ELECTRICITY.

VOL. XXVI. NEW YORK, JANUARY 6, 1904. NO. 1.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

CONTENTS.

EDITORIAL NOTES.

A Court of Patent Appeals. The adjudication of patent suits is a question of vital interest to the inventors of the country, and for this reason the bill recently introduced in Congress by Senator Platt, of Connecticut, to establish a court of patent appeals, and for other purposes, will come in for warm support from American inventors. The bill provides for the creation of a court of patent appeals, to consist of a chief justice and four associate justices, and which shall be a court of record with original and appellate jurisdiction. It shall hold a term annually in the city of Washington and shall exercise original jurisdiction in suits in equity brought by patentees, their assigns, or legal representatives against the United States for infringement of any letters patent, where the cause of action accrues less than six years prior to the filing of the bill of complaint. It may also exercise appellate jurisdiction to review by appeal or writ of error final decisions in the circuit courts of the United States, the territorial or other courts of first instance having jurisdiction of patent or copyright causes, and the Supreme Court of the District of Columbia in all cases involving the validity or infringement of or the title to any letters patent of the United States for any invention or discovery, in all suits brought by the United States seeking the cancellation of any letters patent for any invention or discovery. The decisions of this court in any case within its jurisdiction shall be final.

It is also provided that an appeal may be taken from the ultimate tribunal of the Patent Office as now existing, to the court of patent appeals under such rules as the court may establish, in any ex-parte case in which the final decision of such tribunal refuses to issue letters patent to the appellant for the supposed invention or discovery defined in the claims annexed to his specification, or in any of them; or in any interference case in which the final decision of such tribunal awards priority to another than the appellant; or in any interference case where such final decision awards priority to the appellant, but refuses to issue to him letters patent for his invention or discovery as defined in the interference issue or issues or any of them. There are various other provisions in the bill regarding the procedure before the court.

It is a well-known fact that there is a crying need for a court of this character and in the interest of the inventors of the country it is to be hoped that Congress will enact the necessary legislation to bring it into existence.

Cold Cars. The question as to whether a street railway or other common carrier is violating a provision of the Penal Code if it fails to heat its cars is likely to be examined into as a result of a cold said to have been contracted by Magistrate Flammer in one of the cars of the Manhattan Railroad Company.

The Magistrate claims that the early morning trains on the elevated road are not heated and that such a failure "annoys, injures or endangers the comfort, repose, health, or safety of a considerable number of persons," etc.

The Manhattan elevated road is by no means the only one in this vicinity that subjects its passengers to discomfort and in some cases suffering by a failure to provide heat in extreme cold weather.

A person heavily dressed keeps the blood in circulation by walking, then enters a cold car and sits possibly half to

three-quarters of an hour. The blood is no longer circulating as it should and as a result the feet become cold if not numb. An attack of cold or grippe is frequently the result.

Almost every one who has been forced to travel on the elevated and surface lines in this city has experienced at some time or other this danger and discomfort due to cold cars and if Magistrate Flammer can bring about a better condition of affairs by means of the Penal Code or any other means he will receive the thanks of a large number of the citizens of this metropolis.

Mechanical Stoking in Power Stations. The several forms of mechanical stoking appliances, according to our London correspondent, continue to find their way into electric generating stations in England notwithstanding the view which is occasionally expressed by engineers of some eminence that there is nothing to beat good hand firing. Among those who in the course of the practical operation of their plants have had actual experience with such appliances there is necessarily a great diversity of opinion respecting the comparative merits of the various types, and if we mention the view of one leading central station official, Mr. Albert Gay of the Islington Municipal Electricity Works, we think we shall represent the half-convinced attitude assumed by a good proportion of his fellow workers in central station practice. Generally speaking, Mr. Gay, after making his own tests of rival methods, expresses his ability to appreciate the improved economy of mechanical over hand firing, but beyond that he does not care to go, not being at present satisfied in regard to reliability and cost of up-keep.

As the outcome of his tests of hand and mechanical firing, he prepared some tables, and these indicated, among other things, that with coal having a calorific value of 12,000 to 13,000 B.TH.U. per lb., fired mechanically, the result was nearly equal to coal hand fired, having a calorific value of 14,000 to 14,500 B.TH.U., and that by using a lower grade coal than could be economically fired by hand, a saving of from $1.50 to $1.75 per ton might be effected.

The importance of obtaining the most perfect combustion in order to get the best results from the coal burned, a point which has been pressed home with much persistence by Mr. W. H. Booth and other leading English steam engineers, is discussed by Mr. Gay in a Society of Engineers' paper, and he places it as th chief direction in which the more economical utilization of energy in general, and electrical energy in particular, may be looked for. In this matter, however, he clearly showed that it was quite possible to get in the laboratory, under ideal conditions, such results as could not be expected in actual practice.

Mr. Gay gave descriptions of the various forms of mechanical stoking appliances, dividing them into two main types, viz., top-feed and under-feed, the former being again divided under the sub-divisions of sprinklers and cokers.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The output of 88 electric locomotives during 1903 will probably be doubled in 1904, according to resolutions adopted by some of the larger railway systems to utilize electric power, particularly for yard purposes and on those lines of road now operated by electricity.

The engineers of the Interborough Rapid Transit Company are working on the "third-rail problem," and it is expected that a report will be made soon proposing a number of plans which would be feasible by which the dangers of an exposed contact rail may be obviated. It is said that the engineers favor a plan by which the contact rail will be in short sections, which can either be "cut-out" altogether or may be automatically rendered "alive" as the trains pass along, and be "dead" at all other times.

According to a cable dispatch Sir William Ramsay is authority for the statement that a London firm of analytical chemists has thrown away for many years the by-products obtainable from pitchblende in the process of extracting uranium. It is in pitchblende that radium is now found, and these hundreds of tons of discarded refuse contained in varying quantities the element which in a fluctuating market is worth to-day at least $1,000 a grain.

At a recent meeting of the Berlin Elektrotechnischer Verein, says the *Electrician*, London, Mr. W. von Siemens described a rapid type-printing telegraph on the following principle: A disk, near the periphery of which the letters of the alphabet, figures, etc., are cut out, rotates at a speed of 2,000 revolutions per minute between a moving strip of sensitive paper and a spark-gap. Every time a spark jumps the gap, the letter on the disk which happens to be at the time opposite the gap is photographed. Two thousand letters per minute may thus be recorded on the moving tape, which passes through a developing and fixing bath, out of which it emerges after about nine seconds. To obtain good results, the spark, it is said, must occur with a punctuality of $\frac{1}{40000}$th of a second, and this has been attained by a suitable arrangement of condensers. The messages to be sent are first punched on tape, which is then rapidly run through a rotating sender by means of which corresponding current impulses in rapid succession are sent to the line.

The Automobile Club of Germany has definitely fixed upon June 17 as the date of the great race for the International Cup. The first entries show the international character of the contest, Germany, France, the United States, Great Britain, Italy, Belgium, Austria, and probably Holland and Switzerland, being represented among the competitors.

The cable ship Burnside has been ordered to proceed with Signal Corps men and equipment from Seattle, Wash., for Manila. The Philippine inter-island cables are in great need of repair, and as the Burnside is the only vessel which the Army has fitted for such work it is necessary to send her out at this time. Work on the Seattle-Alaskan cable cannot be recommenced before April on account of ice.

It is gratifying, comments the *Electrical Engineer*, London, that in the struggle going on between factories and domestic industries in some parts of Germany, the latter should occasionally have its share in the achievements of modern engineering. A co-operative enterprise with a view to supplying the domestic weavers (of the silk ribbon trade) in the Southern Black Forest with electric power has lately been started in the Hotzenwald district, it being contemplated to drive by electricity the looms of 500 weavers living in 28 different localities. The first cost of the whole of the power plant is estimated at about $85,000, this sum to be supplied by the Wald-Elektra Sackingen-Waldshut Power Company, apart from a grant by the Government. The significance of this enterprise is its enabling the above branch of textile industry to be preserved as a house industry, securing a yearly income of about $75,000 to the poor inhabitants of that part of the forest.

THE TWO-PHASE POWER TRANSMISSION PLANT AT CHRISTIANIA, NORWAY.

BY FRANK C. PERKINS.

The hydro-electric power transmission plant for supplying current for light, railway and power purposes at Christiania, Norway, is one of the most interesting and unique installations in that country. Two systems were considered for the transmission of power from Skjnerscelven to Christiania, both of which were proposed by prominent Swiss engineers. The one which was adapted was the two-phase alternating current system for generation and transmission by an overhead pole line and underground cables a distance of about 10 km. A receiving transformer station was included for distributing the current, equipped with motor-generators, boosters and storage batteries for supplying the necessary direct current for railway and low tension lighting work.

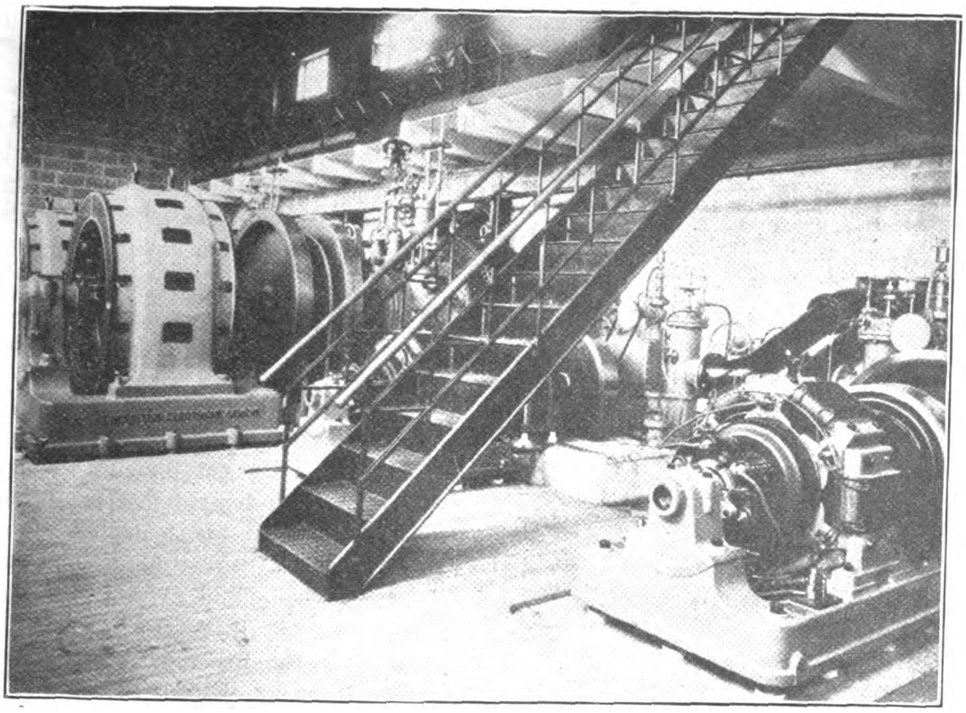

Fig. 1.—Power Station at Skjnerscelven Norway.

The other system proposed was the series direct current system of M. Thury of Geneva, Switzerland, for the generation and transmission and the use of constant current direct current motor-generators at the receiving station. An installation has been in operation for some time at St. Maurice using the direct current generators of this type, a constant current of 150 amperes being used with a potential of 22,500 volts for the power transmission line to Lausanne, which is 56 km. from the generating station. At the receiving station the continuous current is changed to a triphase alternating current for distribution by using constant current direct current Thury motors directly coupled to polyphase alternators generating a 50 cycle three-phase alternating current at a potential of 3,000 volts for distribution. This is a direct reversal of the usual methods of transmission of power as illustrated by the plant at Christiania, which is herewith decribed.

The power station shown in the accompanying illustration, Fig. 1, is located at Skjnerscelven and is equipped with six turbines direct connected to electrical generators by insulating flexible elastic couplings. There is a discharge of 2.5 cubic meters of water per second, the available head being about 100 meters. Four of the turbines have a capacity of 600 hp. each, and operate at a speed of 350 revolutions per minute. These turbines are of the horizontal type constructed by J. & A. Jensen & Dahl of Christiania.

The four 600 hp. turbines drive four Thury bi-phase alternators, which supply a current of 5,000 volts pressure and a frequency of 46.66 cycles per second. The peripheral speed is 27 meters per second at 350 revolutions per minute.

The exciters seen in the view of the interior of power house, Fig. 1, consist of two turbine-driven direct current dynamos of the Thury six-pole type each having a capacity of 50 kw. The excitation current is 17.3 amperes.

The transmission line, pole line construction and terminal station where the conductors pass underground may be noted in the accompanying illustration, Fig. 2. Two of the conductors of the overhead line have each a diameter of 8.2 mm. and the remaining ones are 6.9 mm. in diameter. The aerial line is about 8 km. long and the underground line 1.5 km. The underground cables consist of copper conductors 60 square mm. in cross section and 85 square mm. in cross section.

The receiving station at Christiania, 10 km. from the power plant, is equipped with four motor generators, which change the two-phase alternating current at 5,000 volts per phase to a direct current of 580 volts and 550 amperes for traction purposes. The interior of this sub-station is seen in Fig. 3. There is another sub-station about 1,500 meters away. A booster

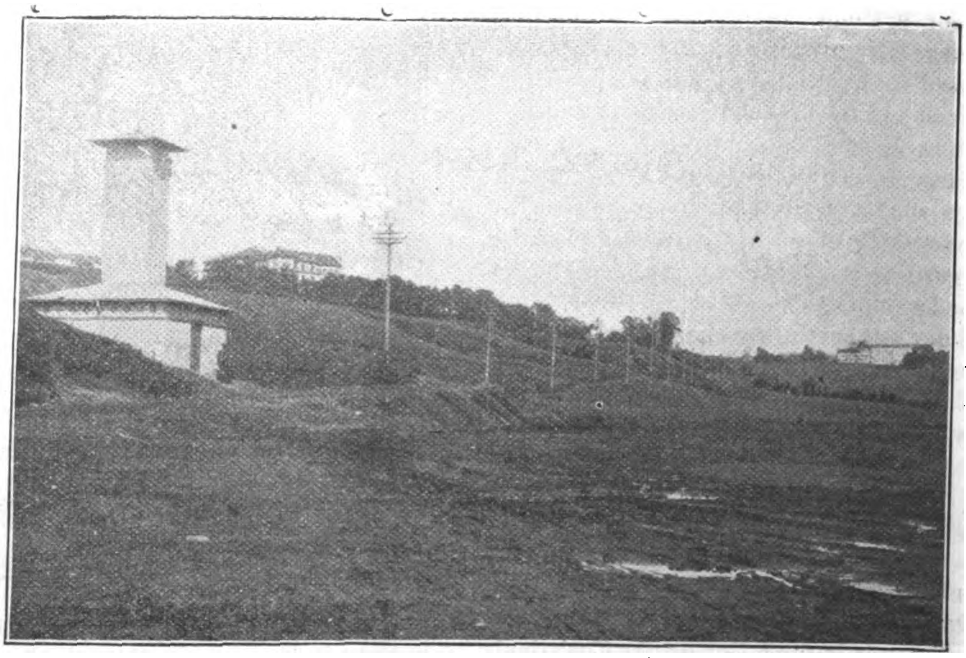

Fig. 2.—Power Transmission Lines, 10 km. Long, from Skjnerscelven to Christiania, Norway.

set is provided for raising the tension for charging the storage batteries used for the railway regulation.

The motor of this set operates at 48.5 amperes and 580 volts and the booster generator coupled to it supplies a continuous current of 500 amperes at a pressure of 55 volts. Mr. Thury has designed an automatic controller for booster sets, which is of more than passing interest. When charging the booster supplies the increased pressure which is necessary to bring the pressure of the storage cells to about 2.7 volts each. During the discharge the voltage of the batteries is raised so that a constant potential is maintained and the automatic controller makes the necessary changes from charge to discharge and vice versa without any attention whatever. All of the variations of potential are quickly corrected without regard to the output or the condition of the battery as charge or discharge. The Thury automatic regulator acts through the excitation of the boosting generator of the motor-generator set. It is operated by a small motor, a mechanical action being used without relays of any kind. A pawl and ratchet are employed which are acted upon by a solenoid and may be made as sensitive as desired. The regulation is ordinarily about 1 per cent. or ½ per cent. above or below normal.

There is in operation at the Christiania station a motor-generator or rotary converter having two fields and two armature windings which is well worth mentioning. This set is used for transforming the direct current used on the railway circuits from 580 volts to 250 volts for use in connection with a steam driven plant when desired. This outfit may also be used for supplying a 580 volt current for the traction work from the 250 volt mains in case there is an accident of any kind on the power transmission line from Skjnerselven or anything the matter with the generating apparatus at that place.

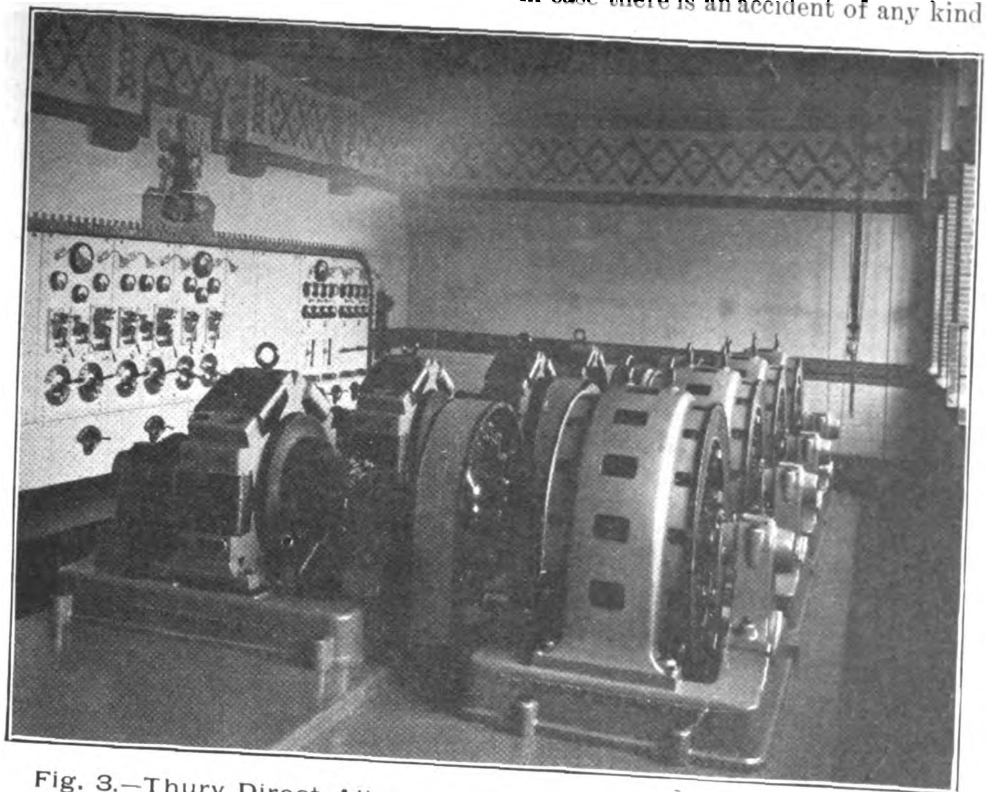

Fig. 3.—Thury Direct-Alternating Current Receiving Sub-station.

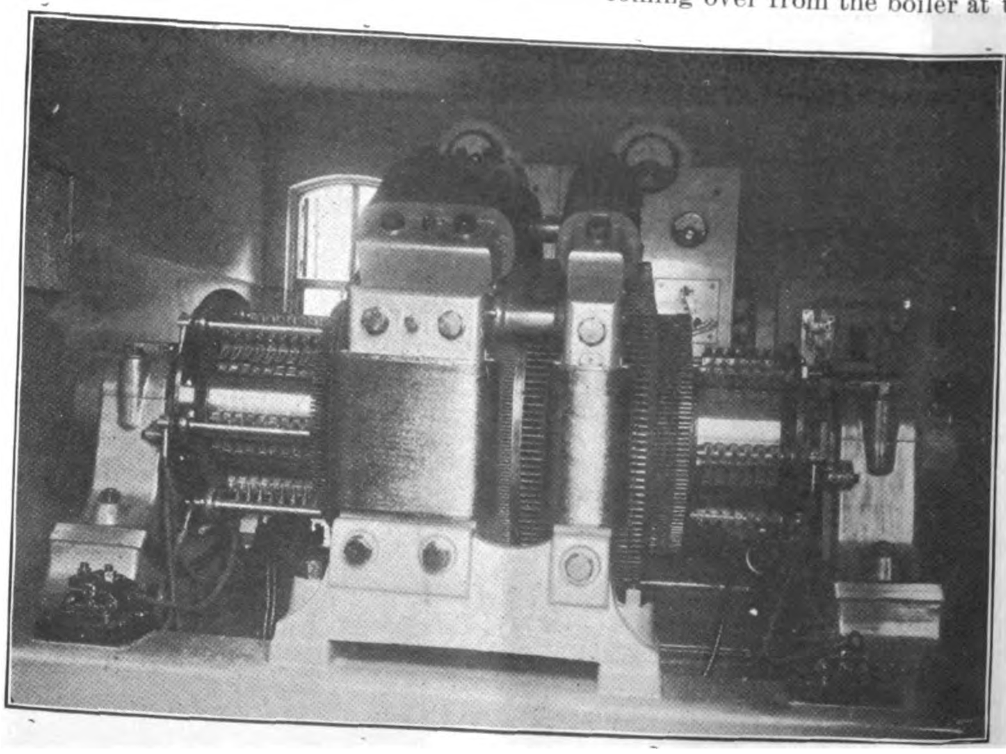

Fig. 4.—Sub-Station at Christiania, Norway.

This machine was built by the Compagnie de L'Industrie Electrique of Geneva, Switzerland, and is of somewhat peculiar construction. The armature and completed machine in operation may be seen in Fig. 4. It is a 400 kw. set with two windings on the armature, supplying a continuous current of 250 volts from one commutator and receiving a direct current of 580 volts at the other commutator, or vice versa.

WHEN AN ENGINE BECOMES A PUMP.

BY W. H. WAKEMAN.

Inasmuch as some engineers seem to think that it is impossible to convert an engine into a pump, under conditions that are ever found in practice, while others are quite sure that it can be done (some of them knowing from experience), a review of conditions which make it possible will be of interest.

When we remember that an engine is made to use steam and not water, and consider that while the former is elastic, the latter is not compressible, for all practical purposes, it is not difficult to understand that much damage may result from substituting water for steam.

For our first illustration suppose that Fig. 1 is the cylinder of an ordinary simple engine, the piston of which is traveling in the direction indicated by the arrow. It is not claimed that this engine will become a pump while carrying a load, neither are we to consider the effects of water coming over from the boiler at this time, as that is another matter to be mentioned later, but I expect to show that it is possible for it to draw in water from the exhaust pipe, and thus cause trouble.

On the engine shown in the cut, the

throttle valve is closed and the momentum of the fly-wheel causes the piston to travel back and forth for about two minutes, as this is possible in practice. Steam remaining in the steam chest and cylinder is soon disposed of, after which the advance of the piston, as shown in the cut, causes a partial vacuum to be formed in the cylinder.

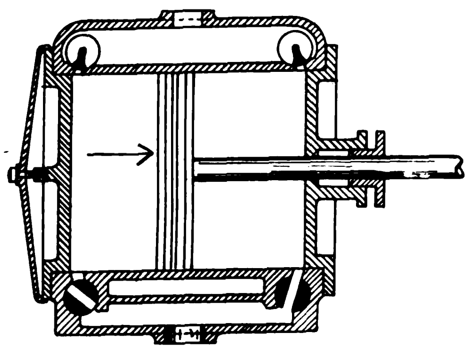

FIG. 1.

The steam valve is now closed, therefore nothing can come in from the steam chest to break this vacuum, and even if said valve was open, nothing could come in as the throttle valve is closed.

The exhaust valve must be closed during the forward stroke of engine, and under ordinary working conditions it will be, as shown in the cut, but after steam is shut off, conditions are changed. As the piston is propelled by the fly-wheel, forming a partial vacuum as before mentioned, outside pressure tends to lift this exhaust valve, but if made as shown it cannot be raised. When an engineer has charge of

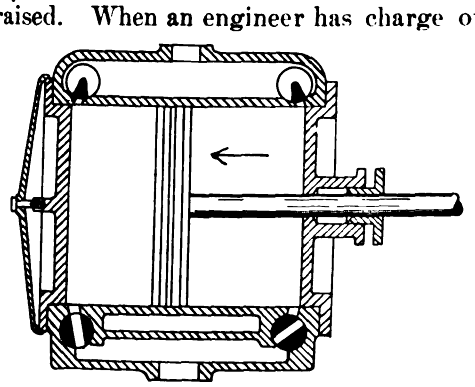

FIG. 2.

such an engine it is not difficult to make him believe that water cannot be drawn into the cylinder, but there are thousands of engines in use in which the exhaust valves can be raised from their seats, and some of them are of the Corliss type too.

Under this condition the exhaust valve will open and if there is water in the exhaust pipe it will be drawn into the cylinder by the pumping action of the piston.

If asked to explain how water can get into the exhaust pipe, the engineer can show that if the heater is not well drained it is quite possible for water to collect there, and be available for trouble making under the described conditions, as demonstrated in my own case some time ago. There are other ways in which water may be present where not wanted, but it is sufficient for our purpose at this time to know that it is found in the exhaust pipe when not wanted.

Assuming that the exhaust valve does e n (ar.d it certainly does in some cases) and that water rushes into the cylinder, let us note the effect.

The piston passes on, reaches the end of its stroke, stops, starts again and makes the return stroke as shown in Fig 2. The piston is now pushing water before it and as the exhaust valve is open there seems to be no reason why it should not pass out of the exhaust port and do no harm, but the piston travels very rapidly at this point, and after it has advanced but a trifle further the exhaust valve will be closed, thus shutting the only exit for the water. As the piston continues to advance its speed is reduced. Before it reaches the end of stroke the entire space between the piston and the cylinder head is filled with the water mentioned. It is claimed that under these conditions the steam valve will open and let the water flow into the steam chest. This may be done in some cases, but not always, for some steam valves are designed so tha they cannot be readily lifted, and others will not lift at all.

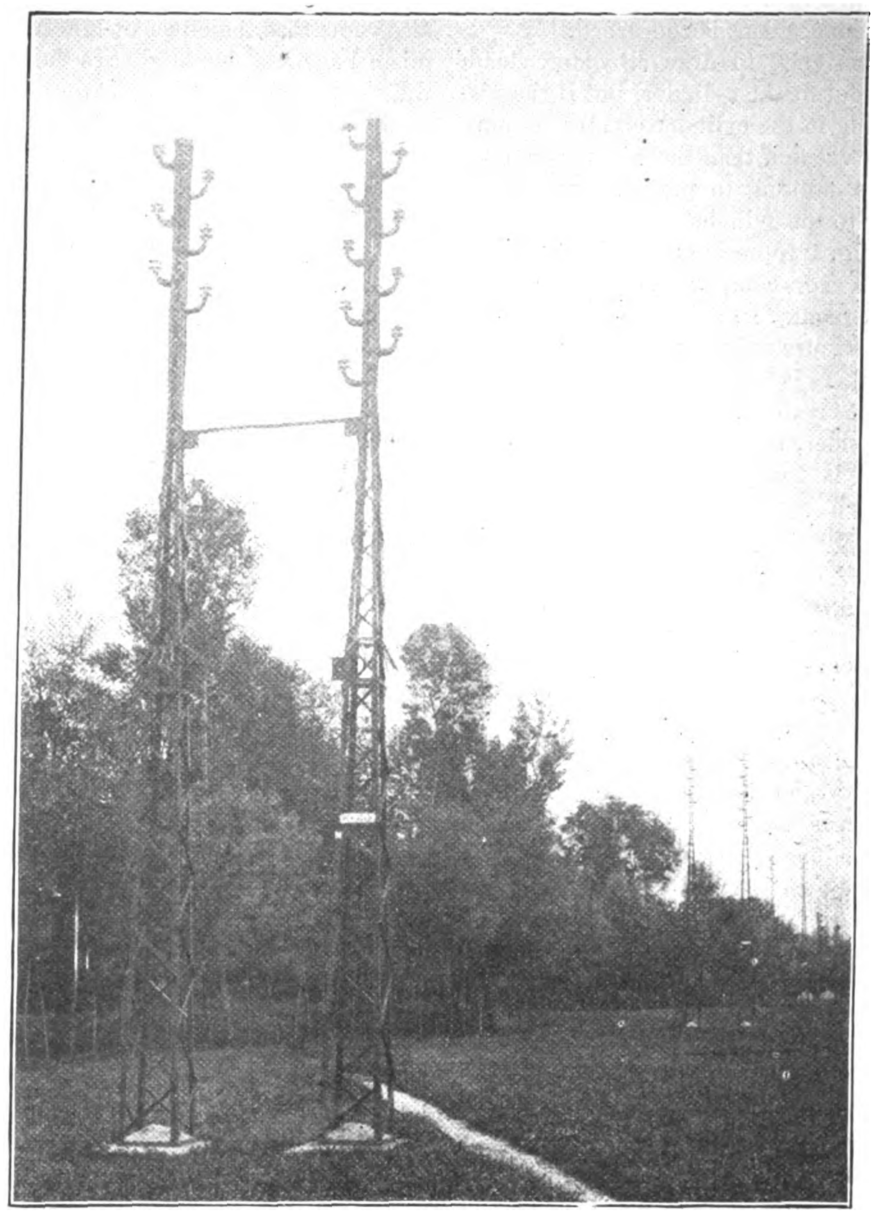

Fig. 5.—Thury High Tension Alternating Current Power Transmission Line at Christiania, Norway.

A short consideration of the matter will show that the crank is near the center at this time, therefore it has what is called a "toggle action," thus bringing very great leverage to bear on the piston, consequently the cylinder head ts blown off or some of the other parts badly bent or broken.

Again referring to Fig. 1, let us suppose that it represents the low pressure

piston of a cross compound condensing engine with an independent condensing apparatus of the jet condenser type.

In this case the exhaust pipe closely resembles the suction pipe of a pump, as it is in direct connection with a plentiful supply of cold water. The air pump is between the cylinder and the water, but it is quite possible to operate this so that it will be practically useless so far as preventing an accident is concerned.

It is designed to draw all water, steam and air out of the cylinder, but if the piston acting in the cylinder creates a more perfect vacuum than the air pump does there is nothing to prevent water from flowing to the cylinder.

As Fig. 1 represents the low pressure side of a cross compound engine it may be, and frequently is, driven entirely by the high pressure piston when starting up, hence there is a good chance for the large piston to create a high degree of vacuum in the cylinder, because on such engines the receiver is frequently large, thus presenting much condensing surface which disposes of the first steam exhausted from the high pressure cylinder before it can reach the low pressure.

A fine engine was wrecked in this vicinity some time ago in just this way, showing that it is a condition which confronts us as well as a theory. Water was drawn into the low pressure cylinder as above described, then when the return stroke was made as illustrated in Fig. 2, after the piston had advanced beyond the point shown, the exhaust valve closed, trapping the water, the piston was propelled by the momentum of the fly-wheel, also by steam pressure acting on the high pressure piston and the low pressure cylinder was broken.

A certain engine of this type, using salt water for condensing purposes, was wrecked in a very similar way, but it was done when shutting down. The engineer closed the throttle valve, either stopped the air pump or allowed it to run slowly, and did not shut off the condensing water. This combination of circumstances made it practically impossible to avoid disaster, for after the throttle valve was closed not only did the pump action of low pressure piston take place, as above mentioned, but the cylinder, receiver and exhaust pipe were filled with steam which immediately began to condense in accordance with natural laws, thus creating a vacuum of high degree, or, in other words, reducing the absolute pressure in these parts until it was much exceeded by atmospheric pressure acting on the surface of the salt water, and as a natural consequence it was forced into the low pressure cylinder.

The engineer claimed that this could not be, and was not done, but when the large cylinder was taken out, unmistakable signs of salt water were found in it, and this evidence could not be successfully disputed.

Due consideration of the above statements will show that it is quite possible to turn an engine into a pump. It will also show that the effect of ignorance and mismanagement is not always the same on different engines, although the mistakes made may be alike, because some of the parts may operate as relief valves, and thus prevent trouble.

While writing on this subject, I wish to make a few statements concerning the idea that a simple engine pumps water out of the boiler under certain conditions, thus lowering the water level rapidly, and causing trouble in the engine. A boiler may foam, or prime, and thus send water over into the cylinder. When the engine is stopped this action will cease as a natural result. This does not prove that the engine pumps it over, but on the contrary it demonstrates that the conditions which caused the boiler to prime or foam have been removed, hence the effect has disappeared.

An engine cannot pump water out of a boiler unless the steam pipe extends down below the water line, as this is a necessary condition which cannot be dispensed with under any circumstances.

Furthermore, if an engine is to pump water in this way, it must be driven by some other power, for water cannot furnish power to raise itself and drive the engine too. Taking all of these things into consideration the expression often used by engineers, to the effect that "she pumps water out of the boiler," conveys a mistaken idea, therefore it should be discarded.

SAFEGUARDS AND REGULATIONS IN OPERATION OF OVERHEAD DISTRIBUTING SYSTEM.*

BY W. C. L. EGLIN.

The distributing system can be considered as one of the integral portions of a power plant and it should receive as careful attention as either the steam plant, hydraulic plant or the electrical plant in the generating station or sub-station. In fact it would appear that the transmission system has to meet more severe conditions than any other part of the entire plant, so that the safety and reliability of the service depends largely upon the amount of forethought given to the plans and to the selection of material.

When it is considered that an overhead distributing system is subjected to many varied conditions, such as the weather, extreme changes of temperature, extraordinary storms, interference from other lines, interference by building operations, excavations, fires and other casualties, and sometimes a willful interference by the public (not to overlook the small boy with a stone), it should be readily appreciated that all these varying conditions must be considered in the construction of the line. There are two divisions of conditions: First, the mechanical or structural features, and secondly, the electrical features.

The first group will include the study of the territory in which the line is to be run, width of streets, kind of buildings, height of buildings; other distributing systems, possibilities of interference with these systems; amount of power to be transmitted, and whether the system consists of a simple power transmission circuit, or one complicated with distributing mains covering the larger part of the territory occupied by the transmission system.

Also to be considered are the weather conditions: wind-storms, rain-storms, sleet-storms, snow-storms, lightning-storms and changes in temperature from summer to winter. The method of erecting the conductors so that they can be properly repaired or additions made without endangering the lives of the men engaged in this work must be carefully planned. Unless these various points are all considered for the construction of the lines no rules or safeguards for their operation will be of material benefit.

The second group includes the electrical requirements: the conductors, the insulating method of support, and the means provided for taking care of any undue disturbances due to lightning or other causes on the line, such as lightning-arresters, fuses, switches, etc.

SPECIFICATIONS FOR MATERIAL TO BE USED.

All of the material entering into the construction of a transmission system should be ordered under specifications which shall clearly set forth the character of the material to be used and also that all of the material will be inspected before it is used on the work, and that tests will be made of samples of all material furnished. The more general requirements are as follows:

Poles.—Poles should be as short as possible to meet the conditions and preferably made of good sound chestnut.

*Paper read at the 182d meeting of the American Institute of Electrical Engineers, New York, December 18, 1903.

Southern cedar and pine poles are sometimes used when chestnut is not obtainable. It may also be necessary to use iron poles under certain conditions; but iron poles are to be avoided, principally on account of danger to linemen and also to the short life of the pole, due to rusting. The pole should be roofed at the top to form a right angle, and gained to form a flat of about 5 inches for the attachment of the cross-arms.

All poles, upon which are located devices requiring regular inspection, should be provided with steps in order to facilitate this work. Spacing of the poles should be carefully considered and should not exceed from 40 to 45 yards. End and corner poles should be braced, and at least every tenth pole throughout the line should be guyed with ¼-inch or ⅜-inch stranded galvanized wire. Regular inspections, at least annually, should be made of the condition of the poles, which is most readily determined by examination at the base of the pole. When poles are used as junction-boxes, that is, when lines are run at right angles and attached to the same pole, special care is necessary. A separate drawing should be made of all such poles, showing the arrangement of the wires—keeping in mind the simplest possible arrangement—as a protection for the men who climb these poles. Switch-boxes, fuses, lightning-arresters or transformers should not be attached to such poles but on the first pole removed from this junction-pole. Junction-poles can frequently be avoided by the use of two poles making a "Y" connection of the line. By this arrangement the connections are very materially simplified.

Cross-arms.—Cross-arms should be spaced at least 24 inches between centers, the top of the first arm being one foot from the top of the pole.

Braces.—Braces should be made of galvanized iron not less than 1¼ inches by $\frac{3}{16}$ inch thick and about 28 inches long.

Pins.—The pins should be made of locust wood well-boiled in linseed oil, and are preferable for voltages of 5,000 volts and under. For high voltages, pins should receive special consideration.

Insulators.—The insulator on the pole line fulfills two functions, viz: The mechanical support of the line, and the insulation. As these conditions vary over a wide range, they must be considered for each condition. This is especially so for voltages of 10,000 volts and over. The two materials of which insulators are usually made are glass and porcelain. The glass insulator is more uniform in quality of material than the porcelain, so that for lower voltages glass insulators are recommended. For higher voltages, porcelain insulators are preferred for the following reasons: Greater mechanical strength, better insulating qualities, and greater ability to withstand severe weather conditions.

Insulators of high voltages should be made up of a number of insulators cemented together so as to obtain more uniform insulation and to increase the factor of safety from defective manufacture. Before being used, each insulator for high-tension work should be tested at voltages in excess of the operating voltage.

The method of attaching the conductor to the insulator should be carefully considered; first, to see that the wires can be properly fastened to the insulator, and secondly, to see that the strain is transmitted without a twisting or bending strain in the insulator; the only strain permitted should be in compression.

The method of distributing the wires on the pole lines depends on the number and character of the various circuits to be installed. For all voltages below 6,000 volts, the wire should be brought out of the station through long porcelain tubes, properly supported; the various circuits being grouped together but well spaced, and preferably being distributed in a single, or not more than a double row of wires. This fan effect allows the circuit to be distributed to the poles without any undue bunching, thus making each circuit easily distinguishable.

The top gain of all poles should be left vacant so that guard-wires can be placed at any point on the line, should they be required. The transmission circuits which are alive 24 hours per day should be placed on the top arm; that is, the trunk lines should occupy the position where there will be the least liability of coming into contact with the other wires or with the men working on the poles. All other circuits should be placed below series arc circuits occupying the lower arms, the distributing series circuit being placed on the house of the lower arms on outer pin occupied by such circuits. The bottom cross-arm should be used for such secondary circuits or low-tension lines as may be required. Space should always be provided for an extra arm on the pole for the erection of a transformer. Protective devices for each circuit may be classified as follows: Circuit-breaker, fuses for branch circuits, and lightning-arresters. Also indicating instruments as follows: Voltmeter, ammeter or wattmeter, and ground detectors.

In the arrangement of the protective devices it is desirable to locate as many of these as possible in the station or sub-station, for the reason that they are more readily inspected and kept in perfect working order, which insures the fulfilling of their functions when required. All circuits of 200 kw. capacity or over should be protected by means of oil circuit-breakers in preference to fuses, to all voltages over 1,000 volts. These circuit-breakers should be attached to both ends of the line, when two or more feeders are used and connected to the same bus; and there should be no other circuit-breaker or fuses which are automatic in action placed at any other part of the line. Small branch circuits may be taken care of when necessary by fuse boxes placed upon the first pole of the branch circuit. These fuse boxes, however, should be avoided whenever possible. This can be accomplished by making a branch circuit about the same as the main circuit, depending entirely upon the circuit-breaker in the station to protect both lines. When small branch circuits are desired, place such fuse boxes. These preferably should be an inclosed fuse of the cartridge type mounted on a porcelain base, the whole inclosed in a fireproof and waterproof compartment. This is usually an iron box with a cover and rubber gasket, clamped so as to make it water-tight.

Lightning Arresters.—Lightning arresters should be installed at both ends of the line, in the station and sub-station, on each conductor. Special care should be used in their installation, and provision made that in the event of a breakdown of the lightning arrester, current may be interrupted by means of a circuit-breaking device.

Series Arc Loop Cut-outs.—These should consist of a mechanically operated switch which closes the circuit at the point of the loop and disconnects the loop from the main line. For the use of constant-potential circuits there may be either a fuse-box provided with solid catches or fuses, depending on the conditions, all of these devices being inclosed in fire and waterproof cases.

Before considering the actions of the safety devices it is necessary, first, to examine the faults which may develop and the functions which the safety devices are required to fulfill. If the condition of a wire parting is first considered, we have first the liability of the wire coming in contact with some of the other circuits; secondly, its liability to fall into the street, and thirdly, its remaining suspended clear of all circuits and the ground.

The first condition, the effect of coming in contact with other wires, would immediately raise the voltage to the more powerful of the two circuits, so it is evident that the insulation of the other circuit must either be as good or there will be a liability of the insulation breaking down at some point on the weaker circuit. This will first be detected at the station by showing that the load is dropped from this circuit, and it demonstrates that the insulation of all circuits must be the same when placed on the same pole-line, unless means are provided for taking off extraordinary high voltages. This can be done by placing spark-gaps, which will relieve the high-tension from any low-tension circuits, or by grounding a wire on the lower-tension circuits.

Wires falling on the ground will indicate immediately in the station, on the ground detector, that there is a ground on that circuit, and instructions should be given that as soon as a ground shows on the circuit and the circuit is not carrying the load to disconnect it.

The third condition will indicate in the station that the load is dropped and will not show a ground. The circuit should be cut off in this case also and inspectors sent out to look after the trouble.

Fourthly, if a wire breaks and falls, crossing other wires of the same circuit, this will cause a rush of current on constant-potential circuit and immediately open the circuit-breaker. In the series arc-circuit it will cut out a portion of the circuit which will be indicated on the voltmeter, showing the necessity of regular voltmeter readings on such circuits.

Interference With Other Wires Falling or Coming in Contact With the Power Circuits.—If these wires cross the power circuit and drop loosely on them, the effect will be to short-circuit the power circuit on constant-potential circuits; the defect develops immediately. The wires either burn off or an arc may be established which will burn off the power circuit, breaking the wires and the connection. The provision should be as the conditions shown for the breaking of a wire. A single wire may merely come in contact with one wire of a constant-potential circuit and assume the same voltage as that circuit; there will be no way of determining this at either the station or the sub-station, unless that wire was grounded and the ground indicated on the ground-detectors. In the event of this falling wire coming in contact with both sides of the series arc-circuit, a portion of the circuit will be cut out and indicated on the voltmeter at the station. Should it come in contact with only one wire of the circuit, no indication will be made at the station unless the wire be grounded. For this reason inspection should be made and all such wires changed so as to come below the power-circuit and not above it. This also demonstrates the necessity of placing protective devices on foreign wires which may come in contact with power circuits.

Lightning Storms.—The installing of efficient lightning arresters as specified may protect the apparatus at both the generating station and sub-station, but fail to protect apparatus at intervening points, particularly the transformers. It is possible that lightning may jump from primary to secondary of transformers during a severe storm. This would be indicated by the primary fuse blowing in the transformer; and after the blowing of the fuse from this cause, tests should be made of the transformer as follows.

It is essential that when a primary fuse on a transformer is blown through any cause, the secondaries should be disconnected from the transformer, and the latter tested to full-line voltage between the primary and secondary coils, so as to determine that there is no breakdown in the insulation between these coils.

There are two methods by which these tests may be readily made by the linemen without removing the transformer: First, take from the station a 600-watt transformer, connect its primary for the line voltage and its secondaries for 100 watts, and connect a 50-volt lamp across the latter. Attach one primary lead of this test transformer to one secondary wire of the line transformer, and place one-ampere fuses in the primary cut-outs protecting the line transformer. Now connect the other primary lead of the test transformer, first to one and then to the other of the main primary lines. If the 50-volt lamp filament becomes red, the line transformer is defective, and should be returned to the station. Second method: If impossible to use the first method, proceed as follows: Attach a short piece of heavily-insulated rubber wire to one of the secondary wires leading from the transformer. Then place one-ampere fuses in the cut-outs, and connect the specially insulated rubber wire first to one and then the other of the main

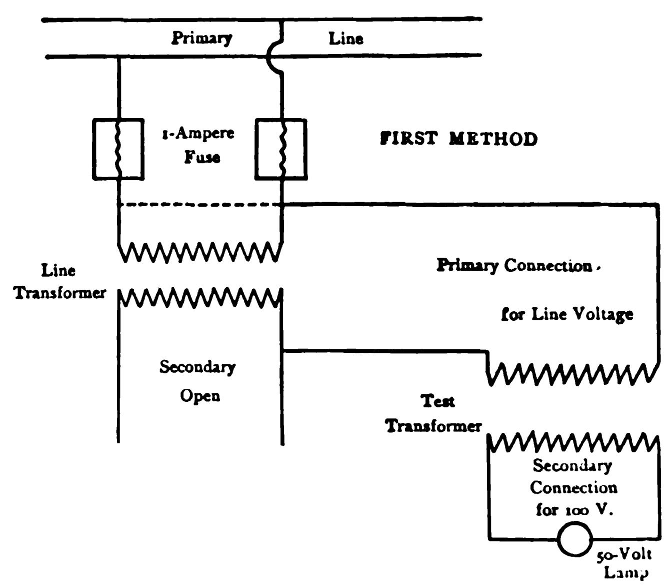

Fig. 1.

primary lines. If the fuse blows, or a spark shows when contact is made, the transformer is defective and should be removed from the line.

In the event of lightning arresters being placed on the pole line, all such lightning arresters should be inspected after each heavy lightning-storm.

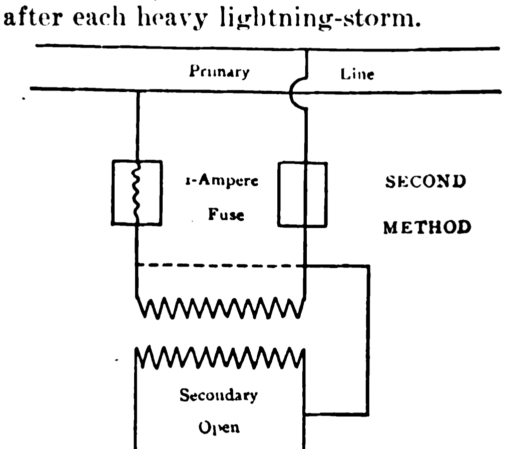

Fig. 2.

Transformers.—Transformers when supported on the poles should be hung on an extra cross-arm provided for that purpose. The primary leads from the line to the fuse-box and to the transformer should be insulated with rubber-covered braid for the line voltage. Transformers should not be attached to buildings or in such locations as to be handled by unauthorized

people, and when they are placed in buildings they should be put in a separate fire-proof closet or room which is controlled only by the operating plant. As it is now the general practice to use oil-transformers it is unnecessary to consider dry-transformers. Inspection should be made to see that the cases are properly filled with oil. This should be done by an inspection force, and not by the men erecting the transformers.

Inspection.—The greatest safeguard in a transmission line is regular inspection. Lines can with advantage be inspected daily, not only an inspection from the ground, but a regular monthly inspection of all devices attached to the line when a continued service is desired.

In may be necessary on some parts of the line to introduce cable. This should be avoided whenever possible for the reason that the conductors are brought close together at this point and static discharge is liable to puncture the insulation; so means should be provided at both ends of the cable to take care of the static. This is best arranged for by a series of gaps of the lightning-arrester type. Standard lightning-arresters can usually be used for this purpose. They should, however, be provided with a small fuse in series with the connection to the line so as to prevent short-circuiting the lines in case of failure of the spark-gaps.

ELECTRICAL STATION PRACTICE.

ARTICLE XVIII.

BY W. H. RADCLIFFE.

The plan of switchboard wiring for alternating current work depends upon the system in use, and this latter may be either of the single-phase, two-phase, three-phase, or monocyclic types. The general principles in all these cases, however, are practically identical, so that there will first be taken up in detail the fundamental one and then in a general way the characteristics in each of the others, thereby enabling the reader to form an excellent idea of this class of work as a whole. As to the fundamental case, reference is here made to the single-phase system and in Fig. 19 a diagram showing the switchboard wiring for a single-phase alternating current generator or alternator, is presented.

In this illustration the alternator is shown at *a*, with its field winding *p* separately excited by the direct current generator *b*. As an aid in reading the diagram the conductors carrying alternating current are represented by solid lines, whereas those carring direct current are denoted by dotted lines. First let us trace out the connections for the exciter *b*. This generator is a shunt wound machine, the shunt field winding being drawn in at *q*. By means of the rheostat *f* in series with *q*, the voltage of the exciter is varied; this, in turn, varies the voltage developed in the alternator *a* since the main leads *d* and d^1 of the exciter are connected through a double-pole switch *g* to the field winding *p* of the alternator. A rheostat *e* is also introduced in this field winding to adjust the pressure of *a*. It may seem unnecessary to employ a rheostat in each of two separate field circuits to regulate the voltage of *a*, but these rheostats are not both used to produce the same result; when a considerable variation of pressure is required, the rheostat *e* is manipulated,

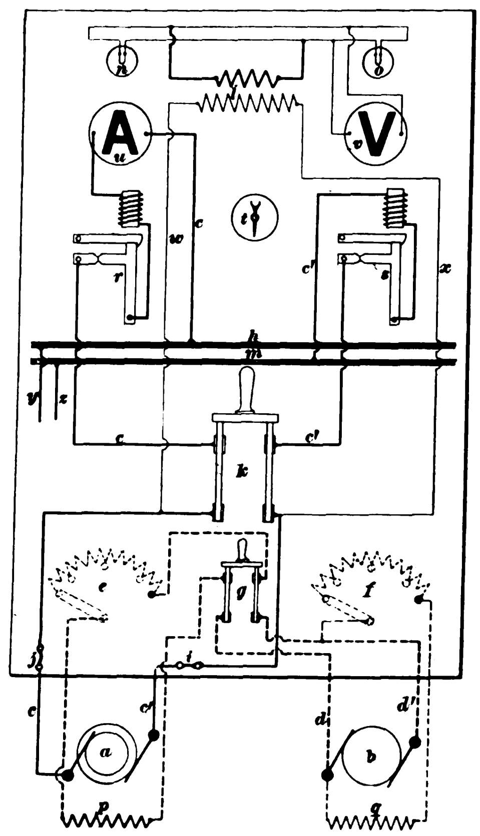

Fig. 19.

whereas for a fine adjustment of voltage the rheostat *f* is preferably employed. Sometimes a direct current ammeter is introduced in the alternator's field circuit to aid in the adjustment.

The main circuit $c\ c^1$ of alternator *a* after being protected on both sides by the fuses *j* and *i*, runs to the double-pole switch *k*. The fuses *j* and *i* serve as a protection to the alternator *a* in case of a short-circuit at the switch *k*. It will be noticed the fuses are of the single-pole type and are mounted a considerable distance apart; this is to prevent any liability of a short-circuit between them in case of action. Inclosed fuses are now used entirely for such work, since in these there is no danger of heated metal being thrown about and causing damage when the fuse wire is melted. Inclosed fuses are also more readily and quickly replaced than open fuses, the containing tube of each being easy to adjust in circuit and when the fuse wire within is once melted the tube is discarded for a new one. The circuit $c\ c^1$ after passing through the switch *k* is further protected on both sides by circuit breakers *r* and *s*. Leaving these protective devices, the left-hand side of the circuit includes the alternating current ammeter *u*, and then through the conductor *c* connects with the bus bar *h*; the right-hand side of the circuit runs from *s* to the bus bar *m* through the conductor c^1. As many feeder circuits, such as *yz*, may be connected to the bus bars *hm* and supplied with current by the alternator *a* as the capacity of this machine will permit. If, however, there be more than one feeder circuit, each one must be wired through a double-pole switch.

In alternating current work the pressures dealt with are much greater than those in direct current installations, so that proportionate care must be taken in the wiring to remove all possibility of grounds. To locate such troubles, however, should they occur, a ground detector *t* is provided. For this class of work the ground detector must be an instrument especially designed for high potential circuits. One of its terminals should be connected to the line and the other terminal to ground; in case of a leak on the line a current will then flow through the detector and by the brilliancy of a lamp connected in circuit the seriousness of the leak may be judged. A step-down transformer *l* is also rendered necessary for the voltmeter *v* and the pilot lamps *n* and *o*, owing to the high voltage in use. The primary winding of the transformer *l* consists of a large number of turns of fine wire, and this is joined by means of the wires *w* and *x* across the main circuit of the alternator, between *a* and *k*. This connection should never be made so that it will be cut out of circuit when the switch *k* is open, for it is always advisable to consult the voltmeter *v* before throwing on the load by closing this switch. The secondary winding of the transformer *l* consists of a comparatively small number of turns of large wire so that the voltage induced in this circuit will be within the limits of the voltmeter *v* and of the pilot lamps *n* and *o*.

In the two-phase alternating current system or quarter phase system, as it is frequently called, an alternator is em-

ployed which generates two alternating electromotive forces having the same maximum values and the same minimum values, but which lag the one behind the other, or in other words, differ in phase by 90 degrees. Since there are two distinctive electromotive forces or currents, these may be handled separately from the alternator on two circuits thereby requiring four wires, or the common sides of the two circuits may be joined together after passing through the switchboard apparatus requiring from there on to the lamps or motors but three wires. Inasmuch as the latter plan effects a considerable saving in copper for the line wires it is commonly employed. In either case the switchboard wiring is practically the same, and differs from that shown in Fig. 19 for the single-phase system in the introduction of an ammeter and a compensator in each of the outside wires, and in the use of a four-pole switch in place of the two-pole switch k. The ammeters, of course, are for measuring the alternating currents in each of the two phases or legs of the system, and the compensators are merely two transformers each with their primary coils in series with the outside wires and their secondary coils in series with each other across the outside wires. The transformers thus connected are known as compensators or potential regulators, and as such compensate for the drop in pressure on either side of the system. The two central terminals of the four-pole switch, which connect directly with the line wires, are joined together by a conductor, and from this point one wire is led off. This wire, together with the two outside wires, from the feeders of the system. One voltmeter will be sufficient on the board if a proper switching device in employed to shift its connections across either of the two circuits; otherwise two voltmeters will be necessary, one bridged across each of these respective circuits. The same reasoning holds true in regard to ground detectors, so that one or two of these will be required, depending upon the aforementioned conditions.

In the three-phase alternating-current system, an alternator is employed which generates three alternating electromotive forces having the same maximum values, and the same minimum values, but which lag the one behind the other, or in other words, differ in phase by 60 degrees. Since there are now three distinctive forces or currents, it is the universal practice to employ for this system three wires. The essential points of difference between the switchboard wiring for this system and that shown in Fig. 19 for the single-phase system, are therefore the use of a three-pole switch in place of the two-pole switch k; the insertion of an ammeter, a circuit breaker, and a compensator in each of the three wires of the system: the presence of two ground detectors instead of one, and the addition of a voltmeter switch if but one voltmeter be provided, or else the installation of two voltmeters connected the one between the middle wire and outer right-hand wire, and the other between the middle wire and outer left-hand wire.

The monocyclic system although of comparatively recent adoption has, owing to its simplicity and the means thereby afforded of operating both lamps and motors from the same alternator, proved itself of great value for this class of work and has therefore become extensively employed. The alternator used generates two electromotive forces which differ in phase by 90 degrees, and by means of three transmission wires these two pressures, one of which has a value of almost .56 of that of the other, are available for use. Alternating-current motors may be connected to the two outside wires and the middle wire or power wire as it is called in the same way as they would be to a three-phase system; while between the two outside wires, arc lamps or incandescent lamps may be introduced into circuit. Since the switchboard wiring for this system is the same as that for the three-wire system already described, no further explanation is necessary.

In the switchboard diagrams previously presented, no lightning arrester connections have been shown for the reason that they are in most cases mounted on the walls of the station near the place at which the line wires enter. If they are mounted outside the station at this point, special precautions should be taken to keep them free from moisture by inclosing them in iron cases, but no matter where they are located it is necessary that they be dry in order to work properly. If possible, one place should be set aside for them and a marble or slate panel provided on which they may be mounted. Wooden supports are undesirable for lightning arresters on account of the fire risk incurred; this, however, may be reduced to a minimum by employing skeleton boards and using sheets of asbestos between the arresters and the wood.

In parts of the country where lightning is of common occurrence, and where overhead circuits are installed which carry high pressures, heavy currents, and extend over considerable territory, it is advisable to have the station well equipped with lightning arresters of the most improved types. Even when lightning arresters are mounted on the switchboard, and this is often done on those wired for alternating currents, they do not present an unattractive appearance, being in one common type composed of seven cylinders of non-arcing metal placed side by side, and separated by air gaps. These cylinders are mounted on a marble base attached to the back of the switchboard near the bottom, and are knurled so as to present hundreds of points for a discharge to take place between them. The two-line wires are connected, one to each outside cylinder, and the middle cylinder is connected to ground. Owing to the air gaps between the cylinders, the alternating current will not flow along this path, but should the line be struck by lightning it will pass freely across them to the middle cylinder and so be conducted to the earth.

In each side of the circuit between the lightning arrester and the switchboard apparatus there should be connected a choking or kicking coil, or what is practically the same thing each of the main conductors may be tightly coiled up for a part of its length. A quick and effective way of coiling up a wire consists in wrapping that part of the conductor in which it is desired to have the coils around a cylindrical piece of iron or wood, the desired number of times, and then withdawing the cylindrical pieces. The coils, each of which may may contain 50 and 200 turns, thus inserted in the main circuit, introduce a high resistance or reluctance to a lightning current, and so prevent the same from passing to the generator; there will, however, be an easy path to earth afforded it through the lightning arrester, as already explained, and so no damage will be done. Coils of the nature just mentioned may advantageously be introduced between the generator and switchboard to take up the reactive current developed upon the opening of the circuit, and also wherever there are suspended conductors to take up the slack by the spring-like effect produced by the coils.

There are certain features peculiar to alternating current switchboards on account of the high potentials cared for thereon, that are worthy of mention. First of all the safety of the attendant should be considered in the design of the board by screening all the exposed terminals on the front of the same in some effective manner. Protection to the

attendant may also be afforded in another way by mounting all the switch mechanism on the back of the board with simply the switch handle projecting through to the front; by pushing or pulling the switch handle the connections may be shifted either to one side of the system or to the other. Less difficulty will attend the breaking of high pressure circuits than would be experienced if the circuits carried lower direct current potentials, because in the former case the arc established between the switch terminals is quickly ruptured by the reversals of the current. When two or more alternators are to be operated in multiple, as will be explained later, a very convenient arrangement consists in mounting the voltmeter on a swinging bracket at the side of the switchboard. The voltmeter may then be swung around in any direction, affording thereby an excellent idea of the pressure while the additional alternator is being switched in. Lastly, in regard to the conductors used in wiring for alternating currents it may be stated that, when the current is such as to require a conductor larger than ½ inch in diameter, it should be stranded. This is necessary in order to limit the drop in volts across it, as otherwise its valve would be considerably in excess of that caused by the resistance of the conductor in ohms.

Carnegie's Gift to Engineers.

Andrew Carnegie's proposal to give $1,000,000 for the erection of buildings for the Engineers' Club and the united engineering societies on West 39th and 40th streets, was, it appears, only a tentative figure, says the New York *Times*, and his actual gift is likely to be largely in excess of that sum.

A circular just prepared for distribution among members of the American Society of Mechanical Engineers tells of the visit of a special committee to Mr. Carnegie and of how he made it clear that the figure he had mentioned need not be adhered to and that the question of cost should be made secondary to the erection of a building which should be a monument to the engineering profession.

The project will be in a measure two separate enterprises, the new home of the Engineers' Club standing on the two lots at 32 and 34 West Fortieth street, and the Union Engineering Building, as the structure for the allied engineering societies, will probably be called, on the abutting property at 25 to 31 West Thirty-ninth street. Just how soon the erection of the buildings will be begun nobody seems to be in a position to state at present, but it will probably be within the next few months, and announcement of a limited competition for selecting an architect will be made shortly.

The project may be delayed somewhat owing to the failure of the American Society of Civil Engineers to signify as yet its acceptance of the plan. Final action by that organization will be taken within two or three weeks, and it was stated Monday that whatever this action is, it will not deter the other organizations from accepting Mr. Carnegie's proposal.

Proposals Invited.

The Interior Department, through the Commissioner of Indian Affairs, is inviting sealed proposals until January 21, for furnishing and delivering the necessary materials and labor required to construct and complete an electric lighting system at the Cherokee School, Cherokee, N. C., in accordance with plans, specifications and instructions to bidders, which may be obtained upon application to the Commissioner of Indian Affairs, Washington, D. C., and at the Indian Warehouse, 119 Wooster street, New York City.

Sealed bids will be received by A. A. Clapp, Sr., city clerk, Alhambra, Cal., up to 7 February 9, for a franchise to erect poles, string wires and construct underground conduits, to maintain and operate the same for 50 years, for the purpose of transmitting electricity for light, heat and power. Each sealed bid must be accompanied by cash or certified check payable to the city treasurer of Alhambra, for full amount of bid, and no bid will be considered unless cash or check is inclosed.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 29, 1903.

Electric Railways and Appliances.

748,268. Magnetic Contact-Box for Electric Tramways. Alfredo Diatto, Turin, Italy. Filed April 8, 1902.

748,322. Trolley Device. Ralph P. Tisch and Robert Kissinger, Hebron, O.; said Kissinger assignor to said Tisch and Charles A. Pence, same place. Filed May 23, 1903.

748,422. Trolley. Walter J. Rowley, Allegheny, Pa. Filed May 7, 1903.

748,441. Trolley. Thomas F. Varley, Lowellville, O. Filed Aug. 14, 1903.

748,557. Electrically-Controlled Railway-Switch. Frederick T. Kitt, Denver, Col. Filed March 4, 1903.

Electric Lights and Appliances.

748,121. Electric-Arc Lamp. Knut Tornberg, Medford, Mass. Filed Nov. 1, 1902.

748,148. Cut-out for Arc-Lamps. Malcolm H. Baker, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Oct. 30, 1902.

748,185. Electric-Arc Lamp for Multiple or Parallel Circuits. Robert H. Henderson, Newark, N. J., assignor to the Westinghouse Electric & Manufacturing Company. Filed March 30, 1903.

748,337-747,338. Socket for Incandescent Electric Lamps. Charles Bakeley, Covington, Ky., assignor of one-half to Chas. Akers, same place. Filed June 18, 1903.

748,445. Incandescent-Lamp Socket. Charles Wagner, Brooklyn, N. Y. Filed May 2, 1902.

Electrical Machinery and Apparatus.

747,926. Multiple-Cylinder Steam-Engine. Henry S. Baldwin, Lynn, Mass., assignor, by mesne assignments, to the General Electric Company. Filed June 1, 1903.

747,927. Exhaust-Relief for Steam-Vehicles. Augustus A. Ball, Jr., Lynn, Mass., assignor, by mesne assignments, to the General Electric Company. Filed June 8, 1903.

747,968. Electric Meter. Ludwig Gutmann, Peoria, Ill. assignor to the Sangamo Electric Company, Springfield, Ill. Filed Jan. 6, 1902.

748,053. Bar for Collecting Electricity for Sectional Circuits. Henri Dolter, Paris France. Filed Feb. 19, 1902.

748,083. Multiple-Cylinder Steam-Engine. Hermann Lemp and Otto F. Persson, Lynn, Mass., assignors, by mesne assignments, to the General Electric Company. Filed Jan. 12, 1903.

748,098. System for Controlling Fluid-Pressure. Edward D. Priest, Schenectady, N. Y., assignor to the General Electric Company. Filed May 21, 1903.

748,123. Electric Switch. Isaac G. Waterman, Santa Barbara, Cal. Original application filed Feb 27, 1902. Divided and this application filed July 1, 1902.

748,145-748,147. Method of Regulating Electric Circuits. Malcolm H. Baker, East Liberty, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 26-28, 1902.

748,146. Constant-Power-Factor Regulator for Electric Circuits. Malcolm H. Baker, East Liberty, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 28, 1902.

748,149. Regulating Device for Electric Circuits. Malcolm H. Baker, New York City, assignor to the Westinghouse Electric & Manufacturing Company. Filed Dec. 8, 1902.

748,182. Magnetic-Power Mechanism. Frederick Hachmann, St. Paul, Minn., assignor of three-fourths to E. R. Wiswell and Benjamin F. Simon, same place. Filed May 8, 1903.

748,228. Turbine-Motor. Byron Stevens, Schoharie, N. Y. Filed July 20, 1903.

748,240. Bearing-Thermostat. George A. Wall, Providence, R. I. Filed Oct. 28, 1902.

748,323. Thermostat. George A. Wall, Providence, R. I. Filed Oct. 28, 1902.

748,354. Automatic Controller for Electric Pumps or the Like. Charles H. Durning, Swissvale, Pa. Filed Jan. 26, 1903.

748,534. Electric Generator for Intermittent Currents. Malcolm P. Ryder, White Plains, N. Y. Filed March 11, 1903.

Telephones and Telephone Apparatus.

748,397. Circuit-Changing Apparatus. William Meyer, Chicago, Ill., assignor, by mesne assignments, to the Stromberg-Carlson Telephone Manufacturing Company. Filed Oct. 10, 1901.

748,524. Telephone-Support. Charles H. Pelton and William Ramsey, Springfield, O. Filed May 29, 1902.

Miscellaneous.

747,949. Signaling System. William H. Dammond, Detroit, Mich., assignor of one fourth to Edward M. Bryant, same place. Filed Nov. 5, 1902.

748,086. Electric Firing-Gear for Breech-Loading Guns. John F. Meigs, Sigard A. S. Hammar and Leighton N. D. Mixsell, Bethlehem, Pa., assignors to the Bethlehem Steel Company, South Bethlehem, Pa. Filed Aug. 27, 1902.

748,143 Wireless Telegraphy and Transmission of Power. James T. Armstrong and Axel Orling, London, Eng. Filed March 11, 1901.

748,309. Electric Heating Pad. William Rickards, Los Angeles, Cal. Filed July 2, 1902.

748 360, Igniting Device. William Gardner, Brooklyn, N. Y. Filed Sept. 27, 1902.

748,408. Elevator Signaling Apparatus. John McLean, New York City. Filed Nov. 16, 1901.

748,442. Vibrator for Induction-Coils. Richard Varley, Providence, R. I., assignor to the Varley Duplex Magnet Company. Filed Nov. 6, 1903.

748,450. Block-Signal System. Elmer E. Wolf and James B. Williams, Springfield, O., assignors to James B. Williams, same place. Filed June 20, 1902.

748,501-748,502. Electric Signaling Apparatus. Felix B. Herzog and Schuyler S. Wheeler, New York City; said Wheeler assignor to said Herzog. Filed Jan. 25, 1886.

THE TELEPHONE WORLD.

Iowa Independent Convention.

The Western Iowa Independent Telephone Association recently held its second annual meeting at the Grand Hotel in Council Bluffs. The principal business was a discussion of plans to secure Independent connection with Council Bluffs, the topic being: "How can we persuade the people of Council Bluffs to allow 10,000 telephone subscribers in Southwestern Iowa to talk with them?" The discussion was opened by H W. Cutshall, of Shelby, who said in part:

"When a merchant in a town tributary to Council Bluffs, takes up his telephone receiver, and calls for Council Bluffs, and is informed that there is no connection with this town, if he is in a hurry for his order, he will naturally ask for connection with Sioux City, Des Moines or some other convenient jobbing point, and Council Bluffs will thus lose much trade. Of course, many of the towns have the Bell toll stations, but this necessitates the customer running over to the booth every time he wants to call, and waiting around, sometimes for half an hour, before he gets the party. In a few of the towns the Bell Company has exchanges, but in most towns where there are both, the Independent telephones are vastly in the majority."

M. A. Reed discussed the subject, "How can we best secure the construction of long-distance copper metallic toll lines in Southwestern Iowa?" and P. C. Holdoegel, "Rules for rural lines and how to enforce them."

It was unanimously decided to call the organization the Southwestern instead of the Western Iowa Independent Telephone Association, and the officers elected for the ensuing year were as follows: President, H. A. Kinrey, Woodbine; vice-president, P. C. Holdoegel, Rockwell City; secretary, J. F. Glenn, Denison; treasurer, A. T. Whittle, Harlan; executive commitee, H. W. Cutshall, W. B. Swaney, M. A. Reed and E. E. Piper.

The Capital City Telephone Company of Raleigh, N. C., with an authorized capital of $200,000, has been incorporated by Julian S. Carr, G. W. Watts and L. A. Carr, of Durham; W. T. Gentry, D. I. Carson, J. W. Crews and Hunt Chipley, of Atlanta, with power to combine and consolidate the Bell and Interstate. There is a third company in Raleigh, called the Raleigh, which will not be affected, and will have the only Independent exchange in North Carolina.

The Supreme Court of Topeka, Kan., has rendered a decision of far-reaching importance to telephone companies operating in that State. It holds that a telephone company must make its peace with adjoining land owners before using a country road as right-of-way for its telephone line.

The following directors have been elected by the Co-operative Telephone Company, of Crawfordsville, Ind.: Samuel Fraley, George W. Bowers, Charles Beck, W. H. Nicholson and M. E Clodfeler.

The North Eastern Rural Telephone Company, Jewett, Ia., capitalized at $1,000, has been incorporated by J. E. Baker, and L. H. Ayer, Jr.

A. C. Hoefner has been elected president, and J. H. Meier, Jr., secretary of the New Melle, Mo., Telephone Company.

Chicago Company to Build.

The Chicago Telephone Company has completed its lease from David C. Cook of the plot of ground fronting on Calhoun place in the rear of 96 Washington street, on which it will construct a building to cost $200,000. The ground is 80 x 72 feet, and is on the north side of Calhoun place, 100 feet west of Dearborn street. The lease is for 99 years from December 1, 1903, at a rental of 4 per cent. upon $200,000. The telephone company binds itself to construct by December 31, 1904, a fireproof building not less than four stories high to revert to the lessor at the end of the term.

The Iowa Telephone Company has removed its general office from Davenport to Des Moines. It is understood the company is intensely interested in legislative matters which will come up this winter. One of the laws that the company desires changed is that regarding franchises in certain cities and towns. The renewal of franchises has been the bane of the company for the past few years, and it is understood an effort will be made to secure legislation that will extend the franchises indefinitely and give the company more rights than it has hitherto enjoyed. President E. B. Smith, it is said, will remain in Des Moines practically all the time during the session of the general assembly or until the matters in which he is interested are completed.

The fight between the telephone companies in Washburn, Wis., appears to be about even, with a little difference in favor of the local Independent company. The old company has refused in many instances to take out instruments when ordered, the result being that the principal business houses find it necessary to keep both instruments. The new company has toll lines in the surrounding places and its line into Bayfield.

The South Shore Telephone Company, whose principal headquarters are at Freeport, N. Y., has filed an amended certificate of incorporation with the Secretary of State. Its lines extend from the Borough of Manhattan on the west to Montauk Point on the east. The capital stock is $20,000, consisting of shares of $25 each, and the directors for the first year are George W. Bergen, Henry P. Libby, William G. Miller, John J. Randall and George P. Bergen, of Freeport.

The borough council of Woodstown, N. J., is considering two ordinances that will mean much to the town. One is for a system of improved sidewalks, and the other for the Eastern Telephone Company, which promises to furnish 'phones at much lower rates, if granted a franchise, than residents are now paying.

The Wilhelm Telephone Manufacturing Company, of Buffalo, N. Y., has been incorporated with a capital of $5,000 to make and sell telephones. The directors are Theodore H. Meyer, Henry A. Brehm and Walter L. Wilhelm.

Three times within a few weeks the telephone booth in the Orange, N. J., station of the Lackawanna Railroad has has been broken open, and all the cash in the automatic device taken.

Telephone Clearing House.

At a conference of representatives of Independent telephone companies recently held in Des Moines, Ia., measures were taken for the establishment of a telephone clearing house. It is the expectation to turn into the clearing house all tolls received by the companies and afterward pro rate them on a mileage basis. The clearing house will be under the direction of a manager selected by the companies.

The stockholders of the local telephone system at Kimball, S. D., lately held their annual meeting. The report of the secretary proved that the company was in good financial condition. Although the system was constructed only last April, and a great many improvements have been made since that time, a dividend of 2 per cent. was declared. The company has no indebtedness. At a meeting of the new directors the following officers were elected for the coming year: President, Dr. Willy: vice-president, C. R. Tinan; secretary, A. S. Stuver; treasurer, H. W. Hinrichs; general manager, A. M. Bowles.

The Central Union Telephone Company at Alexandria, Ind., will put in a new switchboard and change its system from a magneto bell to a central energy system. The strong competition of the Delaware & Madison Counties Company has forced the Central Union people to put up a fight, and while rate-cutting has not yet begun, it is expected when both systems have equal equipment. The city has over 800 'phones, about evenly divided.

The possibility of the postoffice department installing a system for using cars in the tunnels of the Illinois Telephone & Telegraph Company in Chicago, to carry mail between the new postoffice and the railway stations, is said to be strengthening.

The Western Independent Telephone Company, of Kansas City, Mo., has filed a certificate of increase of capital stock from $21,000 to $1 500,000.

A. C. Whidden, assistant treasurer, and M. L. Paige, auditor of the Northwestern Telephone Company, of Minneapolis, Minn., have resigned from their positions.

The Farmers' Telephone Company, operating in the vicinity of Brown Mills, N. J., has reduced its rates to $18 a year, entitling each subscriber to 400 calls.

The Chequest, Ia., Farmers' Telephone Company held a meeting recently and decided to construct a new line to Lebanon.

The new Homer Telephone Exchange at Homer, Mich., has 160 subscribers.

Telephone Incorporations.

The York Telephone Company, Nelsonville, O Capital stock, $1,000. Incorporators: M. S. Wollett, J. W. Bennett, E. R. White, J. M. Bennett and J. G. Filley.

The Egyptian Telephone & Improvement Company, Fairfield, Ill.—to operate telephone, electric light and heating systems. Capital stock, $2,500. Incorporators: C. M. Brock, Luke Whitson and John A. Morian.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Akron, N. Y —The proposition to issue bonds to the amount of $10,000 for an electric light plant was lately carried.

Ashley, Pa.—The Ashley Electric Light & Power Company, was recently incorporated with a capital stock of $30,000.

Athens, Mich.—The Athens Electric Power & Lighting Company has been formed with a capital of $15,000.

Augusta, Ky.—According to plans submitted the waterworks and electric light plant proposed to be built here will cost a total of $47,000 -$11,000 for electric lights and $36,000 for the waterworks.

Barberton, O.—A franchise has been granted to O. C. Barber to furnish electric lights for a portion of this city.

Belmont, O.—Sealed proposals will be received at the office of A. W. Beatty, county auditor, until January 18, for furnishing, installing and equipping a complete electric light plant in the Belmont County Infirmary buildings.

Bernville, Pa.—This village is to be lighted with electricity.

Bradford, O.—The electric light plant here has been totally destroyed by fire.

Brockville, Ont.—The light commissioners have asked for an expenditure of $25,000 on the electric light plant.

Burgettstown, Pa.—Indications are that this town may have an electric light plant soon.

Capac, Mich.—The Fisher Electric Company of Toledo, O., has obtained a contract for the erection of a municipal electric lighting plant here. A 200 hp. boiler, a 150 hp. automatic engine, a 75 kw. alternating current generator and other equipment will be installed.

Durant, I. T.—This town will sell $89,000 bonds for waterworks and electric lights.

Elmer, N. J.—The borough council is considering lighting the streets with electricity.

Fort William, Ont.—This city may issue $15,000 debentures for improving and increasing the power of the electric lighting system.

Hannibal, Mo.—This city may vote on the proposition for the sale of the municipal electric light plant, which is said to be in poor condition, and which would require $10,000 expenditure to put it in proper shape.

Jackson, Mich.—A municipal electric lighting plant is being discussed here.

Joplin, Mo.—Bonds to the amount of $30,000 may be issued for light plant improvements.

Marysville, O.—A franchise for an electric light plant here has been granted D. J. Long, of Mechanicsburg. A $25,000 plant will be erected, work being started at once.

Menasha, Wis.—The Winnebago Traction, Heat, Light & Power Company has asked for a franchise for bringing its light and power wires into this city to furnish commercial light and power.

New Haven, Ind.—The establishment of an electric light plant is favored by the village citizens. H. H Schneilker is at the head of the movement

New Orleans, La.—The city budget for 1904 includes the sum of $8,000 for the installation of new lights.

Northumberland, Pa.—The Northumberland Electric Light, Heat & Power Company has been incorporated with a capital stock of $5,000, The directors are J. Lauterstein, G. R. Van Allen, H. C. Taggert and others.

Orange, Tex.—It is reported that extensive additions to the electric light system of the Ice, Light & Waterworks Company are to be made. S. C. Tremble, Hillsboro, Tex., is general manager.

Plainfield, Ind.—Plans are reported as being made for an electric light plant and waterworks of the recently incorporated Public Service Company, of which Wm. B. Vestal is president. Bids will probably be received soon.

Pendleton, Ore.—The Northwest Gas & Electric Light Company, represented by Dr. F. W. Vincent, has offered to increase its lighting facilities if the city would enter into another contract. The company intends, it is said, to erect a $500,000 power plant in Umatilla County.

Rantoul, Ill —This village is taking steps to have an electric light service.

Rio Vista, Cal.—J. F. Hayes, of the Solano Electrical Works of Vallejo, is said to be considering the establishment of an electric light plant here.

San Pedro, Cal.—W. H. Eddy and W. F. Carlton, of Boston, Mass., have been considering the establishment of an electric light plant here.

Truckee, Cal.—This town is to have a new and modern electric plant, which will furnish a day and night service.

Van Buren, Ind.—M. Otto Bish and John McDougla are organizing a company to build an electric light plant here to cost $10,000.

STREET RAILWAYS.

Allenport, Pa.—The farmers of Allen Township will build an electric line from here to Roscoe.

Beloit, Wis.—An electric road from here to Elkhorn will soon be built by the capitalists now controlling the Rockford, Beloit & Janesville line.

Carlyle, Ill.—The Carlyle Commercial Club is considering a proposition submitted to the Buxton Coal & Mining Company, which proposes to furnish the power to operate an electric railway between here and the mine, provided the citizens build the line.

Centralia, Ill.—The city council is discussing the question of granting a franchise to the Southern Illinois Electric Railway Company to build a line through this city.

Defiance, O.—The Ohio Northern Traction Company, which was recently incorporated with $10,000 capital, will build a line from here to Wauseon.

Harrisburg, Pa.—The directors of the Star Trolley Company, which was chartered to run a network of lines over the lower end of Cumberland County, and in which considerable Harrisburg capital is invested, held a recent meeting at Mechanicsburg, and decided to order immediately all rails and supplies necessary for the completion of the road, which will be started as early in the spring as the weather will permit. C. B. Miller, of this city, is one of the directors of the company.

Hastings, Neb.—Charles A. Baker, a representative of the Nebraska Central Electric Railroad Company, has been negotiating for the right of way for the proposed electric line to connect this city with Omaha.

Liberty Center, O.—The Rapid Transit Railway Company has been granted a franchise to build a line through this town on North street.

Los Angeles, Cal.—An ordinance has been adopted granting to Edward Colter the right to construct, and for 33 years to operate a double track electric street car line in this city, commencing at Main and Jefferson streets. The work is to begin within four months from date of franchise. H. J. Lelaude, city clerk.

Minneapolis, Minn.—The Minnesota Power & Trolley Company will build a trolley line from St Paul through this city.

Mt. Vernon, Ill.—A franchise has been granted by the city council to the Southern Illinois Electric Railway Company to operate an electric railway over certain streets.

Norwalk, O.—There are now very bright prospects for the building by the Buckeye Traction Company of the electric railroad south from here through North Fairfield; Steuben, Chicago Junction and Plymouth to Shelby and thence to Mansfield. Philadelphia men say that they now stand ready to build the road at once if the franchise is renewed and the right of way is again secured.

New Richland, Minn.—John Willis proposes to build an electric line from here to Madison Lake.

Paulsboro, N. J.—The Paulsboro Traction Company has secured all the stock, and work on the new trolley line will commence as soon as spring opens.

Pittsburg, Pa.—The Pittsburg Railway Company will construct a trolley line from Washing to Findleyville.

Portland, Ore.—The Oregon Traction Company will build a line from here to Forest Grove.

Pottstown, Pa.—J. M. Zook, of Exton, is one of the promoters of the proposed trolley road between West Chester and this place.

Springfield, Ill.—A new electric railway company has been organized here to be known as the Springfield, Moweaqua, Sullivan & Mattoon Railway Company, J. B. Titus is president.

Stockton Cal.—R. G. Paddock has been here preparatory to filing an application for a franchise for building a new electric line into this city.

Windfall, Ind.—A right of way for an electric road from Marion to Tipton is being sought by certain parties, and it is claimed it will pass through here. R. M. Van Buskirk is interested.

Youngstown, O.—The Beaver Valley Traction Company will spend $15,000 in improving and extending its lines.

POWER PLANTS.

San Francisco, Cal.—The report from San Jose that valuable water rights had been transferred to Frank Drum, of this city, is believed to be a step toward developing electric power.

Wadhams Mills, N. Y.—D. F. Payne, of this place, who owns a water power here of 48-foot head, is arranging with Port Henry people to install an electric light system there with power transmitted from Wadhams Mills.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅝@12½c; Lake 12½@12⅝c.; casting, 12¼@12⅜c.

The Portable Electric Safety Light Company, Jersey City, has been incorporated with a capital stock of $250,000.

Small lots of stock of Bell Telephone of Philadelphia came on the market on Monday at 52½, against previous sales at 53.

There are now 132,000 telephones in use in Manhattan and the Bronx, being an increase of 76,000 during the last three years.

Electric Vehicle stock on Monday showed considerable strength. The common stock advanced 1¼ and the preferred reached 12½.

Buying in New Jersey Traction in Philadelphia last week advanced the price two points and cleared the market of floating stock as well.

The Interurban Street Railway Company of this city is to assume the new name of "New York City Railway Company" on and after February 10 next.

Justice McCall in the Supreme Court has denied the application of John F. Doyle to examine the books of the Metropolitan Street Railway Company of New York.

The Detroit United Railway Company has sold $500,000 general mortgage 4½ per cent. bonds to E. H. Gay & Co. The price realized was in the neighborhood of 98.

The Russell Electric Company of New York was incorporated at Albany on Monday. The directors are G. W. Russell, Jr., Minnie C. Reddon and J. H. Taylor of New York.

Pittsfield, Mass., capitalists are backers of the proposed electric line between Westfield, Mass., and Hudson, N. Y., as a connecting link in the line to parallel the Boston & Albany its entire length.

The Georgia Electric Railway Company has declared the regular quarterly dividend of 1¼ per cent. on its preferred stock, payable January 20. Books close January 11 and reopen January 21.

The Syracuse (N. Y.) Rapid Transit Company has prepared a report of the business done during the past fiscal year. Some idea of the traffic can be gained from the fact that 15,528,910 passengers were carried exclusive of transfers.

It is figured out that Philadelphia Electric's gross earnings for 1903 will be $3,200,000 against $3,422,411 for 1902 and that the net surplus after dividends are paid will be $788,567 against $563,567 in 1902. But the stock continues weak.

The creditors' committee of the Worcester & Southbridge (Mass.) Electric Railroad Company will recommend the acceptance of the receiver's proposition, which provides that preferred creditors shall receive 50 per cent. and others 40 per cent.

At the annual meeting of the Boston Elevated Railway Company on Monday the old board of directors was re-elected. The total number of stockholders is 2,554, holding 133,000 shares of stock. More than 80 per cent. of the stock is held in Massachusetts.

A dispatch from Chicago says that the Union Traction Company's business in December showed about $2,000 a day gain. The City Railway kept up its average of November, with something to spare. The other Chicago companies made relative gains for the month over those of the corresponding month a year ago, and the preceding month in 1903.

A PRACTICAL BOOK APPRECIATED BY ENGINEERS.

Engineering Practice and Theory for Steam Engineers.

BY W. H. WAKEMAN.

These testimonials should convince everybody interested in steam engineering that this book is well worth the price asked for it.

"After reading your numerous articles in various engineering publications for a number of years past, I was not at all surprised at the lucid manner in which you have written Engineering Practice and Theory, and would therefore commend it to all steam engineers who are desirous of adding to their store of knowledge of the theory and practice of their vocation. I would also particularly commend the several foot notes of advice, which are distributed throughout the book, as being well worthy of emulation. Wishing you every success with this publication, and thanking you for the work you have heretofore written, which has been of great benefit to my fellow engineers, as well as to myself personally, I am very truly yours, CLIFFORD P. WILLIAMS, Supreme Chief Engineer, A. O. S. E., Philadelphia, Pa."

"I have read your book, Engineering Practice and Theory, and find it a valuable book, as it is written very plainly so that any one can understand it. It is full of information that will help any engineer, therefore I recommend it to all such as well worth the money asked for it."—W. H. DAMON, Chief Engineer, The United Electric Light Company, Springfield, Mass.

"It cannot be studied without imparting more than full value for time spent and cost of book. I am sure that any-one who is fortunate enough to get a copy will be well repaid."—ELMER E. MILLER, Consulting Steam Engineer Canton, Ohio.

"I have studied your book and find every point well taken and fully explained." J. H. GRIFFIN, Chief Engineer Ruston Fuel and Ice Company, Ruston, La.

Book contains 184 pages, 5x7½ inches. Sent to any address for $1.00. Address

EDITORIAL NOTES.

Electricity vs. Steam.

The recent heavy fall of snow accompanied by zero weather would seem to have demonstrated the advantage of electric traction over traction by steam.

Last week practically every railroad leading out of New York City was in trouble. The train schedule was a farce and business men living in the suburbs would start for one train and catch the next, after waiting anywhere from one-half hour to an hour on a cold platform or in a colder car.

This enforced delay was to a great extent due to the freezing of the water in the engines. A locomotive would lie out in the yard three or four hours in a zero temperature with the result that the water in the tender would freeze and frequently its pipes as well.

This all had to be thawed out before it could be run in and coupled to its train and travelers had to wait.

But, while the engineers and firemen in the railroad yards were wasting schedule time melting ice, the trolley roads connecting from New York and running out into Jersey were operating practically on time. A few snow plows cleared the track and after that everything was clear sailing, and no matter how cold it became there was no ice on the motors to be melted.

This certainly speaks well for electric traction under severe conditions, and the time will come when up-to-date railroads will operate their short-distance or suburban trains by electricity instead of by steam and save its commuters during the winter months, if not actual suffering, inconvenience and loss of time and money.

Electric Roads as Freight Carriers.

Electric traction is becoming a recognized factor in the transportation of freight for short distances. During the past few years this industry has increased very rapidly, and many rural communities throughout the country depend almost entirely upon the electric railroads for the transportation of their products to nearby markets. The development of this branch of electric transportation has apparently assumed greater proportions in the Middle Western States than in any other part of the country, although there are examples of it in practically all parts of the United States. Electric lines are also used to some exent as "feeders" to steam railroads, hauling the loaded freight cars of the latter from the junction of the two roads to communities many miles distant by means of an electric motor. After the cars are emptied freight destined for points on the steam road, or points on some one of its connecting lines, is then loaded into these cars, which are again delivered to the steam railroad. In almost all cases the management of the electric road is entirely independent of that of the steam road.

The importance of electric lines as freight carriers must be considered, as yet, to be very slight, but there are individual instances of really remarkable development, and several lines give the territory through which they operate service equivalent to that given by the steam railroads, carrying practically all commodities, either in carload or less than carload lots. In many cases farming districts adjacent to cities are served by electric lines; garden truck, milk and live stock are carried to market in freight or express cars, while the farmer procures his supplies from the city in the same manner.

The freight equipment of different roads,

of couser, varies greatly. Where the business is small, a combination passenger and baggage car often meets the requirements, while there are many roads which are able to meet all demands for freight transportation with one or two box or flat cars. There are instances, however, where the freight equipment is very large, reaching as high as 90 freight cars for a single road, and including box, flat and combination cars.

Freight rates vary greatly between different roads for like distances. When an electric line parallels a steam road it generally bases its rates upon those of the steam line. The official classification used by the steam railroads in the territory east of Lake Michigan, Chicago and the Mississippi River, and north of the Ohio and the Potomac Rivers to the Atlantic seaboard, is used to some extent by electric lines in this territory for the purpose of classifying their freight. Printed tariffs embracing a great number and variety of commodities are issued by a number of lines.

A line running out of Portland, Ore., aptly illustrates the development which is, at present, possible in freight transportation by means of electric traction, and a brief history of its growth, therefore, is worth recording. This line has carried more or less merchandise since 1892. The original service was for express packages only, but it has gradually been extended until to-day all classes of merchandise are carried, including farm produce, lumber, and logs in carload lots. The freight equipment consists of 6 freight motors, 10 box cars, 76 flat cars, and four 55-foot combination passenger, milk and express cars, having capacities ranging from 30,000 to 50,000 pounds, and all being equipped with patent couplers and air brakes. Two trips daily are made over the line, and special trains are also operated as business demands. Two freight stations, located at Portland and Oregon City, have been established.

This company has entered into an agreement with the Southern Pacific and Oregon Railway & Navigation Companies for the interchange of freight traffic by which the cars of the above companies are loaded on this company's lines and delivered for shipment to points on the transcontinental lines or east thereof. It has also an agreement by which it handles the pouch mail for the postal authorities between Portland and Oregon City and between Portland and Bering, beyond which point arrangements are now being made for a regular railroad mail service.

While the development of freight transportation by electric lines has been very rapid in the past few years there are many reasons to believe that an increased growth in the future is to be expected. Many roads which have not yet a freight service have indicated their purpose of establishing one, and a number which are carrying only a small amount of freight expect to increase their tonnage by improving their freight-carrying facilities.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The American Institute of Electrical Engineers has accepted the trusteeship of a fund which is being raised by the Edison Medal Association to celebrate the 25th anniversary of the introduction and commercial development of the incandescent lamp. On February 11, Thos. A. Edison's birthday, the inventor will be the guest of honor at the annual dinner of the Institute at the Waldorf-Astoria, and the fund will then be formally presented. The National Sculpture Society will select the competitive design for the medal, which, it has been suggested by Mr. Edison's friends, should be of platinum, in view of the remarkable importance of that metal to lighting and other electrical arts. The permanent maintenance fund will be about $5,000. The medal will be awarded annually to graduating students in electrical engineering.

Prof. Ramsay, when asked recently if he believed radium would ever have a commercial value, said, "I don't believe radium will ever be commercially useful. Medically it will be."

A despatch from Paris on Saturday says: "As a result of recent negotiations it is announced that the Mediterranean Thomson-Houston Company and the German Societe Generale d'Electricite have been amalgamated. The new company will have a capital of $1,200,000. There has been no conclusion of the negotiations for the amalgamation of the French Thomson-Houston Company into the combination, but no hitch has occurred, so far as is known."

The technical committee appointed by the Prefect of Police of Paris to investigate the accident on the Metropolitan at the Couronnes Station last summer, and to suggest improvements, has finished its work, and M. Picou has handed in his report. One of the first things he suggests is that the driver should be able to lift the contact shoe running on the third-rail without leaving his post. As the cars are at present constructed the driver must leave his cabin, go to the side of the car and lift the shoe with his hands. The next important modification suggested is the division of the electric current in the third-rail into sections, so that only a given number of trains may move within a certain section. Each section, moreover, is to be supplied by special cables, which are to be shut off automatically in case of accident or oversupply. Between the stations and at short distances apart all along the line switches should be established by means of which the current may be shut off from all or several sections without resort to the telephone. This would forestall danger from the third-rail in case the passengers had to leave a train between stations.

A special committee of the common council of Binghamton, N. Y., has reported adversely on the question of a municipal electric light plant. It is admitted among other things that the item of labor would cost the city 25 per cent. more than it does the present company.

Electricity in Cincinnati, O., during the next ten years will be sold to private consumers, and for use in public buildings, at not to exceed 12½ cents per kilowatt.

An announcement has been made that a new and unique school of electrical engineering would be founded during the current year by L. L. Nun of Telluride, Col., who is at the head of the electrical power companies operating at Niagara Falls, N. Y., and in the West. It is the intention of the founder to give a full course in mechanical and electrical engineering at Provo Canon, Utah, keeping the students actually employed and under pay during the period of their course.

American electric traction equipment has become so popular in Great Britain that several municipalities in that part of the world specify that bids will only be considered which include Yankee material.

The wealthy Zemindars and Maharajahs of India are using electricity very largely for the lighting of their palaces. The Maharajahs of Dharbanga has just placed an order with a Calcutta firm for the installation of an electric lighting plant for his new palace at Raynagar, which will cost over $100,000.

THE MONEY VALUE OF TECHNICAL TRAINING.*

BY JAMES M. DODGE.

Technical training may be self-acquired or obtained through instruction. The ability to drive a nail properly, or to design and construct the most complex and wonderful of structures or devices, is the result of technical training in but different degree. Up to a very recent date, and within the memory of most of us, the apprentice system and that of independent delving represented the sole methods of acquiring training. Research and investigation carried on in individual lines, with varying degrees of success, dependent upon the mental make-up of the individual were the means of attaining theoretical technical knowledge. The blending of these two methods developed the earlier mechanical engineers and will, even in the future, enable those sufficiently gifted by nature and habits to attain eminence. The progress of the world, however, calls for a better and more speedy means of producing trained men than could ever be developed by the methods of self instruction. The individual striving for manual skill attains his desire under the old apprentice system. Individuals sufficiently gifted rise above their fellows, and become the leaders in their calling. The gratification of a mechanical appetite and the desire to earn more money than his fellows are two moving causes which impel a man towards technical education. A generation or so ago, the universal belief was that the sooner a young man entered upon his apprenticeship, or began practical manual work, the better and more rapid would be his progress in the mechanic arts, and book learning was derided as being purely theoretical and of little practical value. This belief is, even at this date, all too prevalent, largely due to inherited error and to lack of knowledge and reliable data.

Obtaining data from which incontrovertible conclusions can be drawn is now comparatively easy, but a few years ago was practically impossible. We are all prone to take extreme cases of success or failure as the basis of our opinions, and lose sight of the fact that it is the average man whose career shows the true force and direction of the current. For convenience of comparison, I will outline the actual progress made by four groups of men working in the mechanic arts—the unskilled labor group, the shop-trained or apprentice group, the trade school group, the technical school group —and give the results attained. Each group I will refer to as an individual:

Labor.—The first is the laborer, with but primitive and rudimentary training, working under the immediate and constant supervision of a boss, and earning, as the line on the chart indicates, $10.20 per week at the age of 22, his line remaining horizontal through the period of his usefulness. Data are lacking as to his progress before he reaches the age of 22.

Apprentice.—The second, the apprentice or representative of the shop-trained group, of good health and habits, entering a machine shop at the age of 16, earns an average wage of $3 per week for 50 weeks per year, which is about the number actually worked, amounting to $150, or 5 per cent. on $3,000. This, then, is his potential or invested value upon which he draws his interest on pay days.

On the chart accompanying this paper, ruled horizontally, are lines representing amounts increasing from the lower line upward by $1,000 each, starting at $1,000 and terminaiing at the top at $50,000, these representing potential values, upon which 5 per cent. is earned for 50 weeks a year. The vertical lines each represent one year in time, beginning at the lower left hand corner at 16, and progressing in regular order until, at the lower right hand corner, we have 32, representing in all a lapse of 16 years.

To illustrate the progress of the four groups graphically, we indicate on the line representing 16 years of age, and opposite the figure $3,000, the young man just entering his apprenticeship. We will consider him typical of the shop-trained group. Following the line to the right we see his average progress in earning capacity through the ensuing years, noting that at the age of 20 he is earning $9 per week, which is 5 per cent. on $9,000, he having increased his potential or invested value in four years by $6,000.

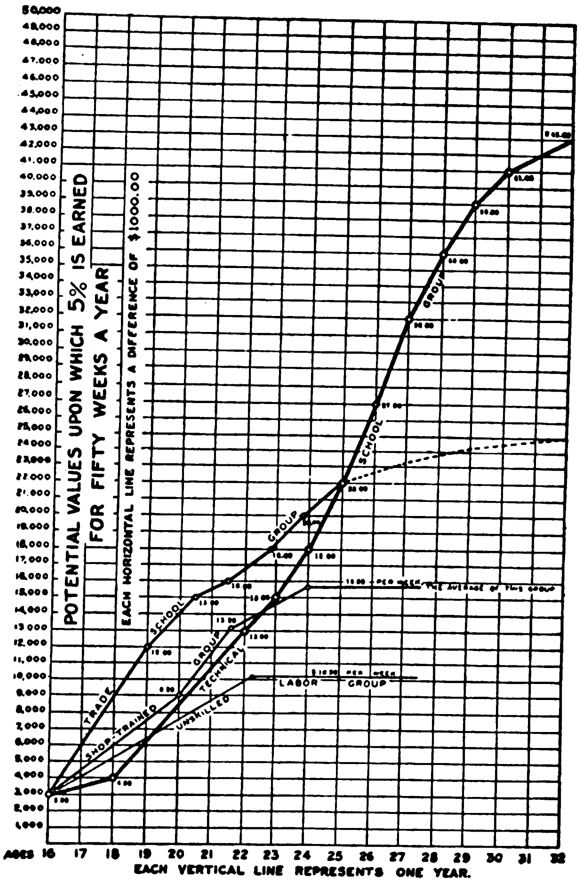

DIAGRAM SHOWING THE MONEY VALUE OF A TECHNICAL EDUCATION.

We now note that his accumulated experience enables him to make more rapid progress for the next year and a half, and from the age of 20 to 21.5 years of age we find that his pay his increased to $13.20 per week, and his potential value to $13,200. He is now approaching his goal, and his line of progress does not continue at the same angle that it followed for the past few years, but deflects towards the horizontal; at the age of 24 we find him earning $15.80 per week, and his potential value $15,800. In other words, in 8 years he has increased his potential value $12,800. Observation shows that 5 per cent. of the apprentices acquiring the machinist trade rise above the line made by our average man, while 35 per cent.

* President's address before the December meeting of the American Society of Mechanical Engineers, held at New York.

follow the line closely; that during the period of training 20 per cent. leave of their own accord, and, as near as can be ascertained, go to other shops to continue in the line originally selected; 40 per cent., however, are found unworthy or incompetent, and are dismissed, probably never rising to the $15.80 line.

Apprenticeship of to-day in many establishments does not make the man, broadly speaking, a mechanic. In a majority of cases he is a specialist or tool hand, and not comparable with the old mechanic, who was a worker in metals, had some practical knowledge of steam and prime movers, could chip, file, work on lathe, planer, drill press, or as an assembler, and was competent to meet the varied and unusual conditions found in general construction and repair work.

Trade School.—The third group of young men are those fortunate enough to have had the opportunity of entering a trade school, which they do at 16 years of age, devoting the next three years of their lives acquiring a trade under competent instruction, and at the same time adding to their store of rudimentary theoretical education. At the age of 19 a trades' school man enters the machine shop and can command $12 per week, equal to the apprentice at 21 years of age, and very quickly makes his employment profitable to his employer. The three years in school have increased his potential value from $3,000 to $12,000, a gain of $9,000. Thus he has caught up with the apprentice entering the shop at 16, and who has been working for five years. Progress of the trades' school group now follows a line which diverges from that of the regular apprentice, and by the time $15.80 is earned by the regular apprentice, the trades' school graduate is earning $20 with a potential value of $20,000, or $4,200 greater than that of the shop-trained man. The trades' school line continues at substantially the same angle up to an earning capacity of $22 per week and a potential value of $22,000. Data are lacking as to the further progress, but the presumption is that this line will bear off more toward the horizontal, eventually paralleling the line of the shop-trained man, but much higher on the chart.

Technical School.—The fourth group we will represent by a boy of 16 studying at school until his 18th year, and preparing himself for admission to one of our higher institutions of technical learning, such as the Stevens Institute, the Massachusetts Institute of Technology, Columbia or Cornell, where, after a four years' course, or at the age of 22, he is ready to begin practical work. The statistics upon which this chart is based show the average starting wage at $13 per week, or the amount earned by the regular apprentice at the age of 21.5, and by the trades' school graduate at the age of 19.5. In other words, apparently a graduate of our technical schools has lost by his six years of preparatory study, having been beaten by the regular apprentice by six months and by the trades' school graduate by 2.5 years. From this time, however, there develops a most interesting and instructive line of progress. The regular apprentice, who is earning $13.50 a week at the time the technical graduate is earning $13, is overtaken in six months, and we find both earning $14 per week, and the technical graduate reaches the $15.80 line nearly one year before the regular apprentice. In other words, while it has taken the regular apprentice from his twenty-first to his twenty-fourth year to increase his wages from $11.50 to $15.80 a week, the technical graduate has done the same in 15 months.

Progress now continues on substantially the same line, and we find the technical graduate earning $22 per week and crossing the line of the trades' school group in three years' time, a worthy tribute to the higher education and attainment.

The line of the technical graduate now continues divergent from that of the trades' school graduate, with earning capacity regularly increasing, and a corresponding augmentation of potential or invested value until, at the age of 32, or ten years after entering upon practical work, we find our technical graduate earning $43 per week and his potential value at $43,000. In other words, six years of preparation have enabled him to distance the shop-trained man and the trades' school graduate overwhelmingly. Bearing in mind that this is an average line, it is of interest to say that most technical graduates with a better record than the one in the chart have devoted even more time to their preparation, either by study or shop-work, after graduation. Those, on the other hand, who have not come up to this average line represent, in the main, men more or less incapable of original work. The reason that higher education, other things being equal, carries with it the ability to earn high wages is that consciously or unconsciously these men are directing and making it possible for large numbers of laborers, shop-trained men and trades' school graduates to perform useful work. A draftsman at his board may never realize that as a result of his drawing 100 men or more may be given employment. His design calling for structural steel, for instance, could not be built were it not for the labor of many men employed in making and rolling the steel before it reaches the shop. Then come the shop men, who cut, punch and shear, and then the erectors, who assemble the structure in accordance with the original plan. For this ability and knowledge our technical man is paid.

It is quite obvious that all workers in the mechanic arts cannot be technical graduates. Some must, through natural limitations, or lack of opportunity, follow the apprentice line, and others the trade school. It is from graduates of the latter that leading shop men and foremen are largely selected. These two classes, supplemented by the technical graduate, constitute the vast army of workers in the mechanic arts.

Thus we see clearly that preparation pays and that it pays in dollars and cents, and that even a long term of years spent in proper study and technical training is a good investment from every point of view.

Of course, apprentices have made and will make, in rare instances, a better showing than the average technical man of the chart, and many of our greatest men have, by sheer force of character, excellence of brain fiber, persistence and self-education risen to pre-eminent positions, independent of all regular systems. To the end of time great examples of this kind will be found. Among those whose names readily come to mind are the elder Krupp, Joseph Whitworth, George M. Pullman, Andrew Carnegie, John Fritz, Prof. John E. Sweet, Edwin Reynolds, George H. Babcock and Coleman Sellers. The same is true of the trades' school graduate, but as said before, we are dealing with the average of each class, taken from actual statistics, with an earnest desire to ascertain the facts, and without any preconceived notion of the outcome.

It may be stated as a truism that every man pays for the amount or percentage of bossing he requires, and conversely, every man's wages increase in proportion to his ability to act as a boss or foremen of himself and others. The lower the wage rate the greater amount of watching and directing constantly required. The slaves of ancient Egypt received no wages, but were treated as horses are to-day. They were fed and sheltered according to the ideas of their owners. No slave worked voluntarily, and the foreman's or leader's excellence was gauged entirely by his

physical strength and efficiency as a driver. This was certainly the zero of labor conditions.

The highest wages are paid to the man through whose ability the largest number of other men may be most profitably employed. He does his work with his brain. Thus, on the one hand, we see manual labor receiving no wages, and on the other mental labor reaping the highest reward. Between these two extremes is found every condition of human life.

A practical man performs his work within the radius of his arm, a technical man within the radius of his brain. The fact is, even to-day, realized by the few, but it is gratifying to know that the number is increasing. The technical training of an individual makes him valuable just in proportion as his ability is manifested by good judgment and perception. Trained common sense receives the highest compensation and reaps the greatest reward. Mental ability to receive ideas and impart them properly and wisely, rearranged and grouped, is typical of the most brilliant mentality; a dull intellect may be compared to blotting paper, fit only to absorb and inter a heterogeneous mass of impressions.

The most interesting of all graphical charts would be that properly exploiting the value of technical training to manufacturing plants and enterprises. To illustrate this more clearly, we may fairly assume that the apprentice of our chart corresponds to the old-fashioned primitive shop, having practically no overhead expense, the proprietor carrying the business "in his hat," priding himself on his non-respective sturdiness, contempt for improvements and personal attention to all details. For his costs he adds together the value of raw materials and labor, and then a few dollars for profit. The line of this establishment would parallel the $15.80 line of our shop-trained group.

The trades' school line on the chart truthfully represents establishments in which some attention has been paid to the improvement of system, with an increased so-called non-productive force, operating possibly in some particulars with brilliancy, but with defective features in others; acknowledging the value of improvement if internally originated, moderately but unconsciously absorbent of ideas from without, but tenacious of dogma and lacking departmental symmetry. Growth, increased earnings and relative immunity from disastrous failure result.

The technical graduate line of our chart represents the manufacturing establishment technically trained and "abreast of the times" in all particulars, and I predict a time not very far distant when it will be almost universally recognized that establishments should be trained as well as individuals, and that the marvelous development in scientific shop practice and management will do for the manufacturer fully as much as technical training is doing for the individual. A change of mental attitude towards the subject of advanced shop practice and management is noticeable to a marked degree. Within a very few years, indifference and antagonism have changed to a growing interest and appreciation.

ELECTRIC LIGHT AND POWER GAS ENGINE PLANT AT USTER.

BY FRANK C. PERKINS.

The city of Uster, near Zurich, Switzerland, has a large number of small industries using more or less small power, and it became evident that a lighting and power plant would be of great value in that vicinity. The installation was supplied with apparatus by the Maschinenfabrik Oerlikon of Oerlikon, Switzerland. It was deemed most advisable to utilize gas-engine-driven electric generators, not only on account of their great simplicity and entire absence of boilers and their accessories, but also on account of the high economy obtained. The central power station included a building large enough to contain the gas plant, an engine and generator room, a storage battery plant, a coal and gasometer room. The power plant at Uster is seen in Fig. 1. The interior of generator and engine room, which covers an area of 234 square meters, is seen in Fig. 2, while the gas generating plant may be noted in Fig. 3, and covers 117 square meters.

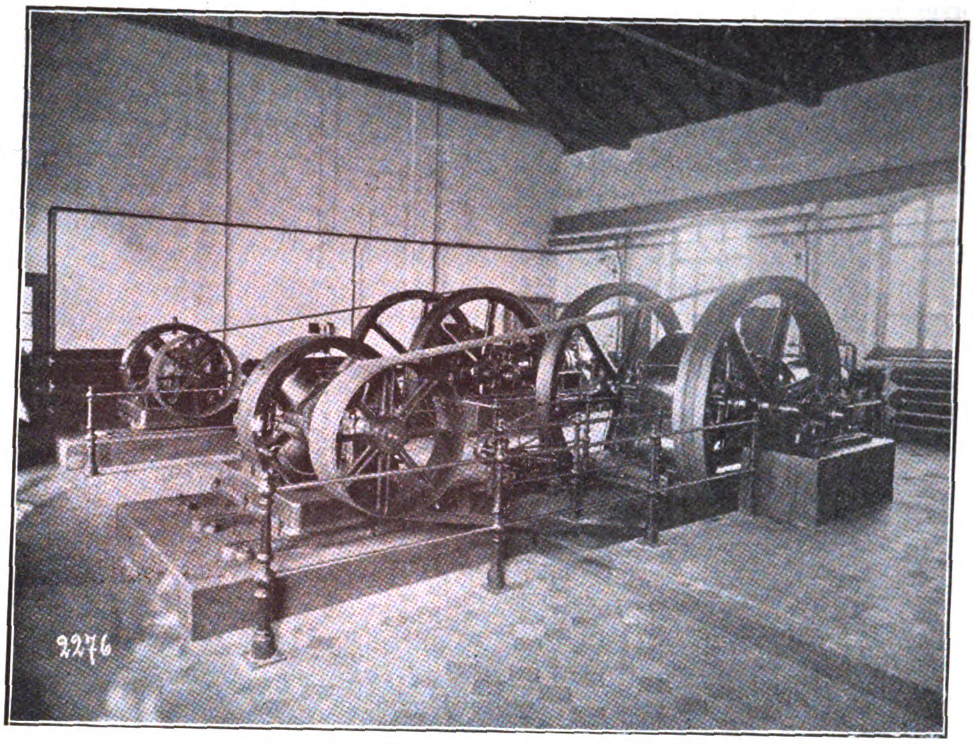

Fig. 2.—Gas Engine and Generator Room in Power Plant at Uster.

Fig. 1.—Central Power Station at Uster.

The gas generating plant has a capacity of 125 hp. and was installed by the Maschinenfabrik Deutz, who also supplied the gas engine now in operation. Both of the gas engines are of the horizontal, single-cylinder type, with a normal capacity of 80 hp. and a maximum capacity of 100 hp. The generators are

driven by the gas engines by belt transmission and heavy fly-wheels are employed for obtaining steady motion. The electrical generators are direct current shunt-wound machines of the Oerlikon type, having a capacity of 80 hp. The generators have each two commutators, each of which supply 200 amperes, while the speed of the machines are 560 revolutions per minute. The pressure at the terminals can be varied from 125 volts to 175 volts, and in charging the batteries series or parallel connections may be used. The armature core of these machines are 520 mm. in diameter and the width 360 mm. The slots in the armature are 116 in number with a section 6.5 x 2.4 mm.

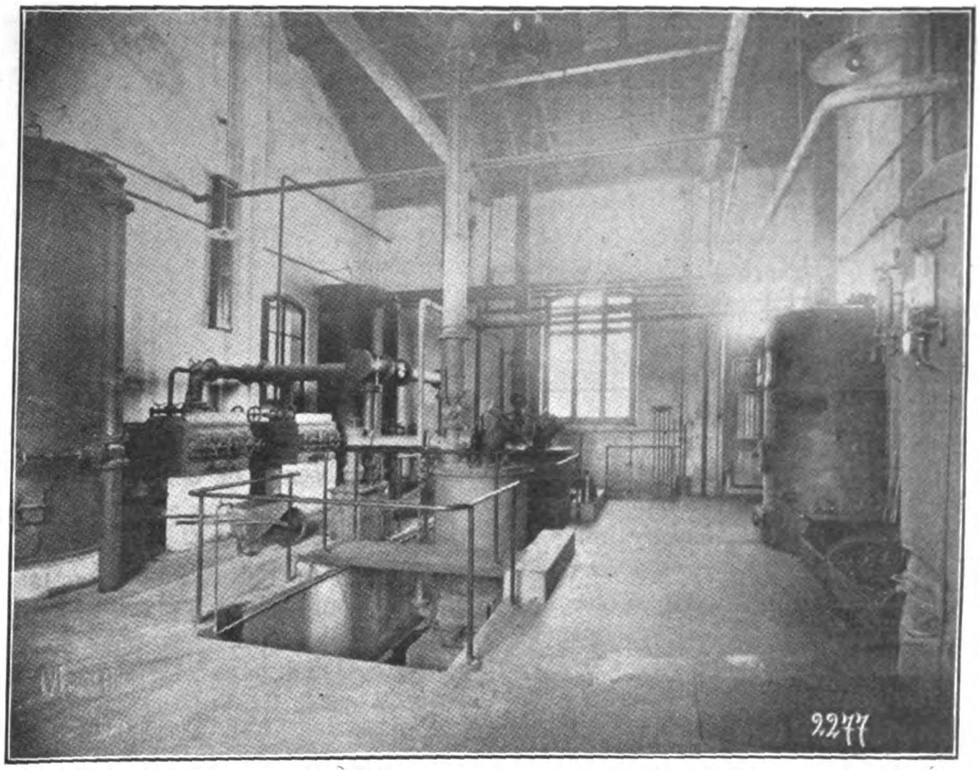

Fig. 3.—Gas Generating Plant at Uster Power House.

Each slot carries two conductors of 4.7 x 5.2 mm. in diameter. Each commutator has 116 segments of pure copper insulated with mica .6 mm. in thickness. The field magnet consists of four coils connected in series, each coil having 968 turns in 16 layers, the conductors being 2.2 x 2.6 mm. in diameter.

The storage battery plant consists of two sets of accumulators, each consisting of 70 cells with a capacity of 800 ampere hours. The light and power distribution circuits are installed on the three-wire system of 250 volts pressure. The motors are operated upon the 250 volt circuits and the lighting service upon the 125 volt. There are several thousand incandescent lights now in operation at Uster of more than 30,000 cp., while the streets are lighted by arc lamps of 9 amperes each. The motor service is quite extensive, from one to five motors being employed in each of the various factories, ranging in power from 1 to 20 hp., the total being in the neighborhood of 140 hp. The accompany- illustration, Fig. 4, shows a 20 hp. motor at Uster driving file machinery in one of the shops.

The charges for incandescent lamps are 1.2 centimes per hour for 5 cp. incandescent lamp, 2 centimes per hour for a 10 cp. lamp, 3.2 centimes per hour for a 16 cp. lamp. and 5 centimes per hour for a 25 cp. lamp, while the yearly rate is 8 francs, 16 francs, 25 francs and 40 francs respectively. The motor rates are 15 centimes per effective horse power hour with a discount ranging from 1 per cent. to 20 per cent. as the size of the motors increase from 9 kw. to 18 kw.

COLLAPSING PRESSURE OF TUBES AND FLUES.

ARTICLE I.

BY W. H. WAKEMAN.

Pressure applied to the internal surface of a boiler shell tends to force it into a true circle (provided it is not already perfect), which is its strongest form, but the same pressure brought to bear on the external surface of a tube or a flue tends to crush or collapse it, and any deviation from true circular form constitutes a weak spot, because external pressure results in an enlargement of the deformity, if the safe limit is exceeded.

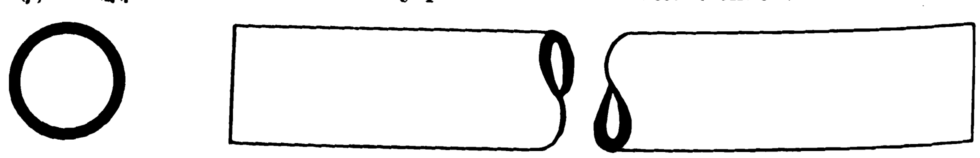

Fig. 1.

The collapse of a large flue is about as dangerous as the bursting of a boiler shell, therefore rules for determining the safe working pressure of the former are as important as for the latter, but they have not received due attention from those who present matter for the consideration of engineers and others interested in steam engineering.

The form of the first flue to be considered is illustrated in Fig. 1. It is of the plain lap welded type having neither riveted seam nor reinforcing ring. Fairbairn's formula for determining the collapsing pressure of this flue has for many years been accepted by the engineering public as a basis for calculations to determine the strength of tubes and flues, but this does not necessarily mean that it is to be taken without modification for all conditions, as it is not elastic enough to meet every requirement of modern practice.

It is introduced here for comment and comparison:

$$9{,}675{,}600 \times \frac{T^2}{L \times D} = P.$$

T = thickness of flue in decimals of an inch.
L = length of flue in inches.
D = diameter of flue in inches.
P = collapsing pressure in pounds.

This formula has been applied to tubes and flues from 3 to 40 inches in diameter, all 16 feet or 192 inches long, and the value of P is as follows:

3	inch tube	.109	inch thick,	199.5	pounds.
4	" "	.134	" "	225.4	"
6	" flue	.165	" "	228.3	"
12	" "	.229	" "	220.2	"
20	" "	.32	" "	257.3	"
40	" "	.5	" "	314.9	"

If we accept the above as correct and use 5 as a factor of safety the safe working pressure will be much less than we carry on at least some of them every day, and this would account for failure of tubes and flues, but there are several reasons why these results should be modified, one of which is that tubes seldom fail in practice even when very high pressures are carried, because their small diameter affords less chance for sudden collapse.

Another reason is that the formula decreases the pressure directly as the increase in length, and of course raises it directly as the length decreases. It is true that Fairbairn found that as the length of a flue increased its collapsing pressure decreased, but we have no proof that it was in direct proportion to the length.

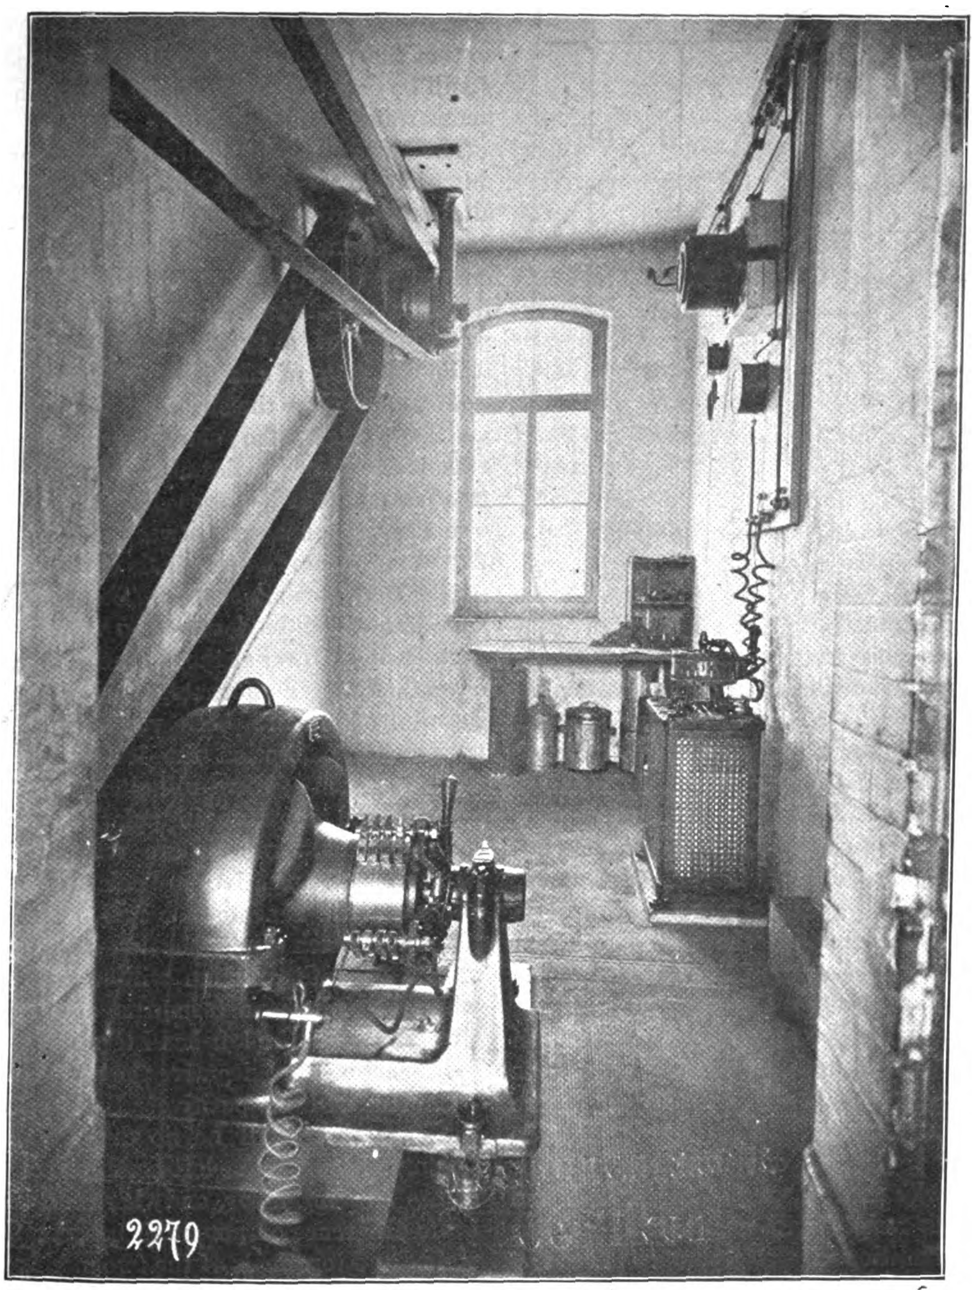

Fig. 4.—Twenty HP. Electric Motor Operating File Machinery at Uster, Switzerland.

This idea has been accepted as correct in some quarters, but not universally.

Applying this formula to a 3 inch tube 4 feet long gives the following result:

$$9,675,600 \times \frac{.109^2}{48 \times 3} = 798.2 \text{ pounds.}$$

It is doubtful if a tube 4 feet long will stand very much more pressure than one 16 feet long, and it certainly will not stand four times as much.

Nystrom drew his own conclusions from Fairbairn's experiments (not from his formula), and gives us the following by which to determine the collapsing pressure:

$$\frac{4 \times T \times t^2}{D \times \sqrt{L}} = P.$$

T = tensile strength of material in pounds.
t = thickness in decimals of an inch.
D = diameter in inches.
L = length in feet.
P = collapsing pressure in pounds.

Taking the value of T at 50,000 pounds and applying this formula to the tubes and flues already used for illustration gives the following result:

3 inch tube	.109 inch thick,	198	pounds.
4 " "	.134 " "	224.4	"
6 " flue	.165 " "	227	"
12 " "	.229 " "	218.5	"
20 " "	.32 " "	256	"
40 " "	.5 " "	312.5	"

The result secured by use of these two formulas, applied to tubes and flues 16 feet long, are practically the same, but when applied to short tubes the difference is plain.

Taking the 3 inch tube 4 feet long, already referred to, this is the value of P:

$$\frac{4 \times 50,000 \times .109^2}{3 \times \sqrt{4}} = \frac{2,376}{6} = 396 \text{ pounds.}$$

As this is just twice the collapsing pressure given for the tube 16 feet long it is a logical conclusion, or at least it is more reasonable than the result secured by the first formula.

Application of it to all the tubes and flues mentioned will show more clearly the difference.

If the reader wishes to take the length of tube or flue in inches and assume 50,000 pounds as the uniform tensile strength of material the following formula may be used:

$$692,800 \times \frac{t^2}{d \times \sqrt{L}} = P.$$

t = thickness in decimals of an inch.
d = diameter in inches.
L = length in inches.
P = collapsing pressure.

It will be noted that in the two preceding formulas the pressure increases or decreases, not directly as the length, but as the square root of the length in feet or inches.

This appears in the light of an improvement, nevertheless all three of the foregoing reduce the pressure indefinitely as the length is increased, which it is difficult to prove correct, because experiments will not sustain the idea. Perhaps this view of the case is unnecessary, as the authors of the formulas intended them for application to lengths commonly found in practice.

As a further illustration of the fact that men do not always arrive at the same conclusion, even when the basis of their knowledge on a subject is common to all, the following formula is introduced. It is given by another engineer who has been studying Fairbairn's experiments:

$$\left(5,358,150 \times \frac{t^2}{L \times D}\right) + 41,906 \times \frac{t^2}{D}\Bigg)$$
$$\pm\left(1,323 \times \frac{t}{D}\right) = P$$

t = thickness in decimals of an inch.
L = length in inches.
D = diameter in inches.
P = collapsing pressure in pounds.

For the purpose of intelligent comparison this formula has been applied to the same examples that were used to illustrate those previously given with the following result:

3 inch	tube	.109 inch	thick,	314	pounds.
4 "	"	.134 "	"	247.7	"
6 "	flue	.165 "	"	352.3	"
12 "	"	.229 "	"	329.8	"
20 "	"	.32 "	"	378.2	"
40 "	"	.5 "	"	452.5	"

It will be noted that these results are decidedly higher than those previously given.

ELECTRICAL STATION PRACTICE.

ARTICLE XIX.

BY W. H. RADCLIFFE.

The operation of an alternator when run singly differs but little from that for a direct current generator. As to the preliminaries, the field exciter must first be started, and for this the directions previously given for starting up a self-excited shunt-wound direct current generator should be followed. At first but a small current should be sent through the field winding of the alternator; then, if the exciter operates satisfactorily and the field magnetism of the alternator shows up well, the load may gradually be thrown on this latter machine until the normal current is carried, the same method of procedure being followed as in the similar case of a direct current generator.

When load is thrown on an alternator there is a noticeable drop in voltage across its terminals. This is caused in part by the demagnetization of the field magnets due to the armature current, and so depends in a measure upon the position and form of the pole pieces as well as those of the teeth in the armature core. The resistance of the armature winding also causes a drop in voltage under an increase of load, which is equal in volts to the product of the resistance of the winding in ohms multiplied by the strength of the armature current in amperes. Yet another cause may be mentioned for the failure of the alternator to maintain its voltage with an increase of load, and this is the inductance of the armature winding, which is in turn due to the positions of the armature coils with respect to each other and also with respect to the field magnets.

When the load on a station increases beyond that which can conveniently be carried by one alternator it becomes necessary to connect other alternators in parallel with it. To properly introduce a new machine in parallel with one already in operation and carrying load, requires a complete knowledge of the situation on the part of the attendant. It may also be added that there is required some experience in this direction, but when knowledge of the situation is grasped the battle is considerably over half won. The case is presented diagrammatically in Fig. 20.

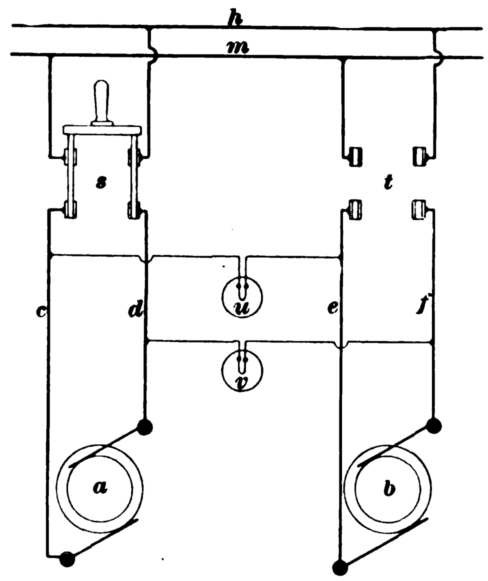

FIG. 20.

In this illustration the alternator *a* is in operation and is supplying current through the mains *c* and *d* and the double pole switch *s*, to the bus bars *h* and *m*. The alternator *b*, on the other hand, is laying idle, not having as yet been called into service. The double pole switch *t* by means of which this machine can be connected into circuit is therefore open. Suppose, now, that an increase of load on the station justifies the introduction of the machine *b* in parallel with the machine *a*. In order that *a* and *b* operate well in parallel, it is necessary that they conform to each other in three respects. The three conditions should also be satisfied before they are thrown together by closing the switch *t*, else the one alternator will be short-circuited through the other and serious results will undoubtedly follow. The conditions are as follows: The frequency developed in each of the two alternators must be the same; the speeds of the machines must also be equal; and the two alternators must be in phase, or as it is sometimes termed, in step or in synchronism with each other.

To satisfy the first of these conditions it is necessary to start up the alternator *b* and regulate its speed in revolutions per second so that the number representing this quantity when multiplied by the number of pairs of poles it contains will be equal to the speed in revolutions per second of the alternator *a* multiplied by the number of pairs of poles on *a*. When such is the case, the frequency in cycles per second of each machine will be the same, since the frequency is always equal to the product of the number of pairs of poles by the speed in revolutions per second. Then, with the speed of alternator *b* maintained constant at the value found to satisfy the first condition, the second condition imposed must be fulfilled by regulating the field current of *b* so that the voltage across the mains *e* and *f* will be equal to the voltage across the mains *c* and *d*.

The third condition, namely, the determination of the instant at which the two alternators are in phase with each other, is a much more difficult proposition to encounter than the other two. The solution of the problem consists in employing some form of a synchronizer to show when this state of affairs occurs, and when therefore to close the switch *t*. For a low voltage system, the simplest and most effective form of synchronizer consists of two incandescent lamps as shown at *u* and *v* in Fig. 20 connected between the mains that extend from the terminals of the same polarity on each alternator. The lamps *u* and *v* must each be designed to supply its rated candle power at the normal voltage developed by the alternators. Now since the alternators are both running under normal field excitation the left-hand terminals of each of them will alternately be positive and negative in polarity, while the right-hand terminals are respectively negative and positive in polarity. If, however, the machines *a* and *b* are in phase with each other, the left-hand terminals of both of them will be positive while the right-hand terminals are negative, and when the left-hand terminals of both machines are negative the right-hand terminals will be positive. Such being the case, there will be no difference of potential between the left-hand terminals of the two machines, and there will also be no difference of potential between the right-hand terminals of the two machines.

If, therefore, incandescent lamps be connected as shown in Fig. 20, one between the left-hand terminals of the alternators and one between the right-hand terminals, neither of these lamps will be lighted when the machines are in phase. The instant there is a difference of phase between the alternators, however, there will be a difference of potential between the terminals of the same polarity on the machines and the lamps *u* and *v* will both light, attaining full candle power when the difference of phase has reached a maximum, since then the full potential of each machine will be supplied to the

lamps. A very slight change in speed will soon shift forward the phase of the one alternator relatively to the other, lowering in consequence the difference of potential between the terminals of like polarity, and causing both the lamps to give a bright red glow. As the alternators continue to come closer in step, the red glow will gradually fade away until the lamps become dark. Then the switch *t* may be closed, thereby throwing the two machines in parallel. If the intervals between the successive lighting up of the lamps are of short duration it is advisable to wait until these become longer even though the other conditions are satisfied, because where the phases pass each other rapidly there is a greater possibility of not bringing them together at the proper instant. An interval of not less than five seconds should therefore be allowed between the successive lighting up of the lamps, before closing the switch.

The switch *t* having been closed with no unusual disturbance occurring in the circuits, attention must next be given to equalizing as nearly as possible the loads upon the two machines. This is accomplished by a proper handling of the rheostats in their respective field circuits so as to cut down as far as possible the current passing between the alternators, and which is known as the synchronizing current. The synchronizing current will have a minimum value when the deflections on the ammeters in the main circuits of these respective machines are as small as it is possible to make them without decreasing the voltage developed in the armature of either alternator. When the alternators are once in phase and running smoothly, they will need but little attention, inasmuch as there always exists a strong tendency for them to remain in synchronism with each other.

When the alternators to be switched together in parallel are each designed to produce a high electromotive force, the simple synchronizing device employed in Fig. 20 is inadequate. By the use of two step-down transformers, however, the same principle is applied in a modified form, and is then well adapted to the case in hand. Each of the two transformers must be connected with its primary coil across the terminals of one of the alternators, and the secondary coil of each is joined in series with the other, and these in series with two incandescent lamps. The connections between the secondary coils of the transformers are such that when each is subjected to the same conditions the action of the one coil opposes that of the other, and as the transformers are both of the same design there will consequently be no voltage across the lamps when the alternators are in phase with each other. If the ratio of each transformer is such as to give, for example, 100 volts across its secondary terminals, then the two incandescent lamps since they are joined together in series must each be designed for 100 volts. When, therefore, the alternators are directly opposite in phase to each other, both the lamps will burn brightly; as the alternators come together in phase the lamps will produce less and less light, until when the machines are exactly in phase no light will be emitted at all. Then the unloaded alternator may be switched in parallel with the other, and the same method of procedure followed as described for the similar case in a low voltage system.

If the conditions are of such a nature that the alternators may all be started together, the paralleling of them becomes a simple task. After bringing each of them up to its proper speed so as to obtain equal frequencies, the main switches may be closed, thereby joining their armature circuits in parallel. As yet, however, their respective field windings have not been supplied with current, so that no harm can result in doing this. The exciters of these machines after being joined in multiple should then be made to send direct current simultaneously through the field windings of the alternators, and from this stage on the directions previously given may be followed in detail.

If alternators are directly connected to each other, or to an engine, they must necessarily run in the same manner at all times. If, therefore, the machines when connected in this way are properly adjusted so that they are in phase with each other, their operation in parallel is still a simpler task than when they are all started together but are not directly connected.

When it is desired to cut out of circuit an alternator running in parallel with others, its main circuit should be opened either by means of a switch or circuit breaker, according to which of these is best designed to be used for this purpose with the voltage employed in the system. No attempt should be made to cut down the voltage of the alternator before disconnecting from the others; while this might be done with advantage were the alternator running alone, there would be a tendency in the case of a parallel connection for the alternator or alternators continuing in operation to force a current through the machine in question and thereby cause considerable damage.

Alternators are seldom if ever connected in series, for the reason that the synchronizing tendency previously mentioned as peculiar to these machines causes them to oppose each other, and fall out of phase when they are joined together in this way. If, however, they are directly connected to each other, or to an engine, so that they necessarily keep in phase all times, and thus add their respective electromotive forces instead of counteracting them, it is possible to operate them together in this manner.

INTERURBAN ELECTRIC TRACTION SYSTEMS--A. C. VS. D. C.*

BY P. M. LINCOLN.

Electric traction is peculiarly an American institution, that is, it has found its widest application in American communities and has been developed chiefly by American engineers. In America practically every town of over 5,000 inhabitants is provided with an electric traction system. In other parts of the world it is only larger centers of population that are so provided.

Practically all the traction work in America has been done by direct current. The alternating current traction system, although it has received considerable attention from American engineers, has not until recently been favorably considered by them. In Europe, on the other hand, the alternating current traction problem has received a large amount of attention. The polyphase induction motor has been developed by European engineers for traction purposes and a number of installations have been made in Europe with apparatus of this character. American engineers have consistently refused to adopt the polyphase induction motor for traction purposes on the ground that it is not suitable for that purpose. The principal reasons for this stand are two in number.

1. That the polyphase induction motor is inherently a constant speed motor and, therefore, not adapted to traction purposes. Continual change of speed is one of the characteristics of traction work. The direct current series motor is peculiarly adapted to this class of work because it is inherently a variable speed motor. At one definite speed the polyphase motor is an efficient machine, while at all other speeds the efficiency cannot be greater than the ratio of the actual speed

*Abstract of paper read before the Electrical Section of the Canadian Society of Civil Engineers, Nov. 19, 1903.

to the synchronous speed. For instance, if the actual speed at which a given induction motor is working is 10 per cent. of its synchronous speed, the power utilized is at most only 10 per cent. of the power put in. In traction work a large part of the work done is necessarily at speeds below the maximum attained, and at these lower speeds the maximum economy that can be obtained from induction motors is necessarily small.

One expedient used by European engineers is to reduce this source of loss is the use of motors in concatenation or in tandem, that is, the secondary of one motor is fed into the primary of another on the same car. If the pair of motors thus concatenated are wound for the same number of poles, this expedient has the effect of making the synchronous speed of each of the pair of concatenated motors one-half that which it is when not in concatenation. It is equivalent in direct current practice to throwing two shunt motors in series. Up to the half speed joint, therefore, there is a gain of economy by this arrangement. By winding the two concatenated motors for different numbers of poles more than one point of maximum economy can be secured between zero speed and full speed, but this arrangement has the disadvantage of being able to use but one-half the total motor capacity above half speed while the greatest expenditure of energy takes place above half speed. In order to secure the advantages of concatenation, however, it is necessary to add largely to the weight of the electrical apparatus. European practice has been to equip cars with four motors, two main motors and the other two being used only while the car is below half speed. Above half speed the motors are running idle and are doing no useful work. The energy required to take care of the additional weight is an offset against the energy which is saved by concatenating the motors. For long runs this expedient would probably be detrimental since the energy taken up to transport the extra weight would be more than equivalent to the energy saved at the start.

2. The second reason against the use of polyphase induction motors for traction purposes is the necessity for providing at least two overhead conductors. If the track be not used as one of the conductors, then the necessity arises of using at least three overhead conductors. Maintenance of insulation on such overhead conductors when they are at high voltage is naturally a difficult problem, much more difficult than to maintain the insulation between a single conductor and ground, as would be the case in a single-phase system.

American engineers instead of endeavoring to adapt the unsuitable induction motor to traction purposes, have devoted their energies to the development of a suitable alternating-current motor. The idea of using a series motor operated by alternating current is not new. The only alternating current single phase motors which have a characteristic suitable for electric traction purposes are those of the commutator type. In no other type of motor are the speed and torque characteristics such as to be suitable for traction purposes. In the commutator type alternating current motor, the speed and torque characteristics are practically identical with these characteristics in the direct current series motor. As early as 1893 extensive experiments were made by the Westinghouse Electric & Manufacturing Company on this class of motors. In fact, the experiments went so far as to equip a car with two motors of this type and the car was put into actual operation. Moreover, the frequency and voltage for which the motors were designed was practically the same as those for which the more recent motors were designed. These early motors were considerably smaller in capacity, however, and the trolley voltage was less. Further, the method of controlling the speed was by control of voltage. Although the early motors were successful as motors, the alternating current system as a system was not thought at that time of sufficient importance to continue the developments along this line. In other words, the time was not yet ripe for the development of this system. Interurban electric traction work, such as exists to-day, was not at that time thought of, and this is, in the writer's opinion, the peculiar field for the alternating current traction system.

In considering the general problem of electric traction, the question naturally arises—what is gained by the use of alternating current over direct current? and the converse of this question also naturally arises—what is it necessary to sacrifice in order to obtain the benefit of alternating current traction? An analysis of the advantages and disadvantages of these two systems may be of interest. Although many of the following points have been treated in previous papers, particularly that of Mr. Lamme, acting chief engineer of the Westinghouse Electric & Manufacturing Company, before the American Institute of Electrical Engineers in September, 1902, it is hoped that repetition of some of the points mentioned will not be out of order.

The principal advantages of the alternating current electric traction over the direct current are as follows:

1. Limits to trolley voltage are removed.

2. Avoidance of rheostatic losses.

3. The necessity for rotary converter sub-stations abolished.

4. Manual attendance at the sub-stations done away with.

5. Danger of electrolysis by return current avoided.

To take up these points more in detail:

1. Voltage Limit Removed.—The greatest item of cost in the electrical equipment of interurban traction systems as they exist to-day is that of secondary distribution. This item of cost usually carries somewhere between 25 and 50 per cent. of the total for electrical equipment and is usually much nearer the latter figure than the former. Six hundred volts at the motor in a direct current traction system is practically the limit at which present designers and manufacturers are willing to guarantee their operation except in some special cases. This necessarily limits the voltage fed into the secondary distribution system to, say, 700 as a maximum. The consequence of this comparatively low voltage is naturally a high cost for conductors of this secondary distribution. The alternating current system, providing as it does the possibility of greatly increasing the voltage of the distributing system, thus cuts down largely the cost of this distributing system.

Another point which militates against the use of direct current is that when large units are used it is difficult to collect the large amount of current for their operation. For this reason, as well as an advantage in cost, trolley construction has been largely replaced by the third rail for interurban work. By raising the voltage of the secondary system the current taken by a locomotive may be reduced, and consequently the difficulty with collecting devices may be made to disappear.

2. Rheostatic Losses Avoided.—In the direct current system the voltage at the car is practically constant, and while the counter EMF. of the motors is building up the excess voltage must be taken up by resistance. At the start, therefore, a large rheostatic loss occurs. With the alternating current system, on the other hand, the voltage at the car may be controlled by suitable means and the rheostatic loss thus avoided. When stops are few, and consequently runs are long, the

rheostatic loss in the direct current system is a small proportion of the total, and, therefore, under these conditions this advantage of the alternating current system is not so greatly marked. With short runs, on the other hand, and consequently frequent starts, the rheostatic loss with the direct current system amounts to a considerably greater proportion of the total loss and the alternating current system, therefore, can have the greater advantage.

3. Necessity for Rotary Converters Avoided.—The cost of sub-station equipment constitutes one of the large items in the cost of the electrical equipment of an interurban road. In this sub-station equipment by far the largest item of cost is the rotary converters. In the alternating current equipment the rotary converter has no place, thus avoiding not only a large item of cost but also one of the largest items of the loss of power.

(To be continued.)

Electro-Capillary Recorder.

A dispatch from London states that Armstrong & Orting, inventors of the wireless telephone, have invented an instrument they call an electro-capillary recorder. Cables are enabled to receive from 400 to 500 letters a minute. The arrangement seems indifferent to leakages and faulty cables.

Looking for a Factory Site.

The stockholders of the Otto Gas Engine Works, which is located at 33d and Walnut streets, Philadelphia, Pa., have decided to increase the capital of the corporation from $600,000 to $2,500,000, and build a large new plant just as soon as the management can find a suitable site for the purpose. Large gas engines, producer gas plants, launches and marine engine, gasoline hoists, compressors and other adaptations of the gas engine will be built at the new plant. A suitable site must contain not less than 30 acres, must be located on a good water front and must have good railroad facilities.

Proposals Invited.

Sealed bids will be received by the board of public works of Jamestown, N. Y., consisting of P. H. Hoyt, Samuel A. Cralson and W. I. Bylstone, until January 15 for the following: One 350 hp. compound condensing engine, one 200 hp. alternating single-phase, 60 cycle, 1,100 volt dynamo, and one 200 hp. turbo-generator set.

Northwestern Electrical Association Convention.

Following is the programme of the twelfth annual convention of the Northwestern Electrical Association to be held at the Hotel Pfister, Milwaukee, Wis., Wednesday, Thursday and Friday, January 20, 21 and 22:

Wednesday, morning session—Convene at 11:30. Roll call, reading of minutes, president's address, secretary and treasurer's report.

Afternoon session—Appointment of nominating and membership committees, applications for membership, reports of all committees except nominating, miscellaneous business. Papers: "Storage Batteries for Central Station Work," J. M. S. Waring; "Peculiarities of Magnets," Richard Varley; "Rectifiers," W. Scheidel.

Evening—Theater party.

Thursday, morning session—Papers: "Double Current Generators in Their Connection with Double Current Supply," W. L. Waters; "Central Station Heating," W. H. Schott; "Standard Practice in the Use of Alternating Current Electrical Apparatus," J. J. Gibson.

Afternoon session—Report of nominating committee and election of officers. Papers: "Steam Turbines" (illustrated), James Lyman; "Rectifiers," Prof. B. F. Burgess; illustrated lecture on radium, Prof. R. A. Milliken.

Evening—Annual banquet.

Friday morning—Unfinished business. Adjournment.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 5, 1904.

Electric Railways and Appliances.

748,591. Third-Rail Cover. Henry F. Duffy, Seattle, Wash. Filed June 20, 1903.

748,592. Third-Rail Protector. Henry F. Duffy, Seattle, Wash. Filed June 20, 1903.

748,619-748,620. Electric Railway. Charles J. Kintner, New York City. Filed Sept. 22, 1899, and March 10, 1902. Renewed May 19, 1902, and May 22, 1903.

748,621. Safety System of Electric Railways. Charles J. Kintner, New York City. Filed Nov. 15, 1902.

748,810. Electric-Car Plow. William F. Taylor, Jr., Providence, R. I., assignor of one-half to Thomas D. Taylor, Boston, Mass. Filed March 30, 1903.

748,815. Railway Block-Signal and Switch. William F. Taylor, Jr., Providence, R. I., assignor of one-half to Thomas D. Taylor, Boston, Mass. Filed March 30, 1903.

748,872. Electric-Railway System. William G. Lowrie, New York City. Filed June 21, 1901.

748,987. Trolley-Harp. Edward D. Rockwell, Bristol, Conn. Filed Nov. 7, 1903.

749,042. Electric-Railway System. William M. Eader, Middletown, Md. Filed July 27, 1903.

Electric Lights and Appliances.

748,574. Apparatus for Producing Electric Arcs for Heating and Lighting Purposes. James I. Ayer, Cambridge, Mass., assignor to the Simplex Electric Heating Company, Boston, Mass. Filed June 22, 1903.

748,599. Incandescent-Electric-Lamp Socket. Henry A. Framburg, Chicago, Ill. Filed April 9, 1903.

748,904. Electric-Arc Lamp. Luis Wirtz and Thomas Hamilton-Adams, London, Eng. Filed Feb. 4, 1903.

748,915-749,016-17-18. Electric-Arc Lamp. Edward H. Belden, Fort Wayne, Ind., assignor to the Westinghouse Electric & Manufacturing Company. Filed first Aug. 6, 1900; all renewed May 11, 1903.

Electrical Machinery and Apparatus.

748,572. Apparatus for Controlling Current-Supply to Electrically-Heated Tools. James I. Ayer, Cambridge, Mass., assignor to the Simplex Electric Heating Company, Boston, Mass. Filed June 1, 1903.

748,573. Electrically-Heated Tool. James I. Ayer, Cambridge, Mass., assignor to the Simplex Electric Heating Company, Boston, Mass. Filed June 15 1903.

748,635. Automatic Brake for Controlling Switches of Electric Motors. Frederick A. Muschenheim and William F. Hendry, New York City, assignor to the Western Electric Company. Filed June 2, 1902.

748,638. Electric-Circuit Closer and Breaker. Thomas H. McQuown, Biggsville, Ill. Original application filed Sept. 26, 1902. Divided and this application filed Jan. 5, 1903.

748,639. Fuse for Electric Circuits. Theodore Nagel, Chicago, Ill., assignor of one-half to Lathrop H. Collins, same place. Filed April 24, 1903.

748,771. Electrically-Driven Centrifugal Machine. Henry G. Morris, Philadelphia, Pa. Filed May 8, 1903.

748,812. Switch-Throwing Mechanism. William F. Taylor, Jr., Providence, R. I., assignor of one half to Thomas D. Taylor, Boston, Mass. Filed March 30, 1903.

748,813. Contact-Shoe. William F. Taylor, Jr., Providence, R. I., assignor of one-half to Thomas D. Taylor, Boston, Mass. Filed March 30, 1903.

748,814. Semaphore Mechanism. William F. Taylor, Jr., Providence, R. I., assignor of one-half to Thos. C. Taylor, Boston, Mass. Filed March 30, 1903.

748,906. Transmitter. Ernest E. Yaxley, Chicago, Ill., assignor to the American Electric Telephone Company, same place. Filed April 13, 1901.

748,907. Electric Dynamo or Motor with Alternating Field. Rudolf Ziegenberg, Schoneberg, Germany. Filed April 25, 1903.

748,961. Electric Coupling. George A. Le Fevre, New York City. Filed Jan. 28, 1903.

749,085. Electrical Cut-out. Columbus B. McPherson, Birmingham, Ill. Filed Nov. 14, 1902.

Telephones and Telephone Apparatus.

748,690. Telephone-Transmitter. Charles F. Bennett, Waterloo, Ia. Filed Nov. 29, 1901.

748,716. Wire-Connector. James S. Ford, Chicago, Ill., assignor to the American Telephone & Telegraph Company. Filed Oct. 9, 1903.

748,980. Telephone-Exchange. Nils E. Norstrom, Chicago, Ill., assignor of two-thirds to John Anderson, Salina, Kan., and M. E. Richardson, Sterling, Kan. Filed March 16, 1901.

Miscellaneous.

748,571. Electric Soldering-Iron. James I. Ayer, Cambridgeport, Mass., assignor to the Simplex Electric Heating Company, Boston, Mass. Filed Nov. 13, 1902.

748,597. Wireless Signaling Device. Lee De Forest, New York City. Filed Dec. 24, 1902.

748,609. Production of Hydroxids and Oxids of Metals by Electrolysis. Frederick F. Hunt, New Brighton, N. Y., assignor of two-thirds to Maas & Waldstein, New York City. Filed Jan. 22, 1903.

748,749. Electrical System of Heating. Edward H. Kitfield, Swampscott, Mass. Filed Oct. 26, 1903.

748,824. Block-Signal System. Joseph Weatherby, Jr., Wilmington, Del. Filed July 24, 1902.

748,940. Method of Producing Electrodes for Storage Batteries. Frederick A. Feldkamp, Newark, N. J., assignor to the Electra Manufacturing Company. Filed April 17, 1903.

748,941. Electric Signal System. Howard A. Fessenden, Detroit, Mich., assignor to the Detroit Electric Signal Company. Filed Dec. 16, 1901.

748,970. Automatic Signaling Apparatus. Ira A. Michael, Chicago, Ill., assignor of one-half to John H. Reynolds, Troy, N. Y. Filed June 27, 1902.

749,033. Telegraphic Receiving Apparatus. Frederick G. Creed, Lenzie, Scotland, assignor to himself, and William Arthur Coulson, Glasgow, Scotland. Filed Aug. 9, 1902.

749,105. Electric Signal. Baptist H. Scott, Allegheny, Pa. Filed Jan. 20, 1903.

749,131. Wireless-Signaling Apparatus. Lee De Forest, New York City, assignor to the Wireless Telegraph Company of America. Original application filed March 6, 1901. Divided and this application filed Dec. 8, 1902.

THE TELEPHONE WORLD.

Bell People Losing Prestige in Bureau County, Ill.

The Central Union Telephone Company, known as the Bell Trust, is said to be losing its hold rapidly in Bureau County. Several years ago it had about 70 telephones in use in Princeton. Now it has about a dozen and in a vacant store room is piled up dozens of discarded instruments. The Central Union has no longer any service between Princeton and Tiskilwa. The business gradually dwindled down, and a few weeks ago the poles along the highway between the two towns were chopped down. The company had a toll station at Dover, but has been requested to remove it. It is claimed there was only about 20 cents worth of business done the last month and that it does not pay to bother with it. Here are some of the towns in Bureau County which the Trust cannot call up: Tiskilwa, Dover, Walnut, Kasbeer and New Bedford. The Princeton city council passed an order giving the company 60 days in which to remove the unused poles and wires and directed the superintendent of streets at the end of that time to chop down the poles, if the company has not complied with that order.

President C. A. Barron, of the Skagit Farmers' Mutual Telephone Company, has lately been in Everett, Wash., and announced that in a few weeks his company would make application for a franchise for an Independent telephone company in Everett, to connect with the services already established in 18 towns in Snohomish and Skagit Counties, and with the Independent Telephone Company at Seattle. This company has just secured a franchise at Arlington and expects to have its system operating there within 30 days. It is building a line from Silvania to Marysville, a few miles from Everett. B. H. Vollans, formerly manager of the Sunset Company in Everett has associated himself with the Independent concern.

The Independent Telephone Company of Le Mars, Ia., which is operating an exchange in opposition to the Iowa Telephone Company, has filed articles of incorporation with the Secretary of State for a new company. The capital stock of the new company will be $25,000. A. C. Colledge is president and I. S. Mahan is secretary.

The Missouri & Kansas Telephone Company completed the work of installing a long distance line into Waco, Kan., a short time ago. An exchange has been placed in that town, which is also connected with private lines running from the homes of many farmers in that vicinity.

The Georgia Railway & Electric Company, of Atlanta, has just completed a telephone system by which the cars are directed when trouble arises or a wreck occurs.

It is reported that a telephone line will be constructed through Brownsburg, Pa., along the main river drive, in the near future.

The Elyria, O., Telephone Company has increased its capital stock from $50,000, to $100,000.

Three Telephone Companies' Earnings.

News from St. Paul, Minn., states that three telephone companies lately filed reports of their gross earnings with the State Auditor. The Northwestern Telephone Company stated that the earnings of the company in Minnesota had been $902,802.30 for the year. This sum is subject to a tax of 3 per cent., making a sum of $27,084.07 for the State Treasury. The Minnesota Telephone Company earned $4,796.77 last year, making its contribution to the State $143.90 The Shakopee Telephone Company made $2,186.70, and will pay a tax of $65.60.

Weather Forecasts by Telephone.

The Colorado Telephone Company, at Denver, has established the system of telephoning the weather forecasts to its patrons. About 240 Colorado towns and the farmers living near them receive daily reports. The system also extends to New Mexico, where 17 cities are given a daily report.

Arrangements have also been made to enable the Indianapolis weather bureau to announce the weather forecast each day at 10 o'clock to the residents of the extreme part of Northern Indiana. The plan is to telephone the report to Lagrange, Shipshewana, Millersburg and Middlebury, from which centers it will be distributed to all telephone patrons at the hour named. A similar service has long been in use in Central and Eastern Indiana.

The Home Telephone Company has added many customers to its lists in Waterloo and Seneca Falls, N. Y., and has now secured the right of way between Waterloo and Geneva, and is soon to commence the erecting of the poles and the stringing of the wires to that city. The company has arranged to connect there with the local line of Waterloo and will thus be placed in direct communication with the western part of the State as far as Buffalo, a connection that will be of great advantage in Waterloo.

The Kensington Telephone Company, at Kensington, Md., has been organized with the following officers: President, Byron A. Chapin; vice-president, Eugene Jones; secretary, George R. Taylor; treasurer, C. E. Bruington. It is proposed to institute local service at the start and expand as occasion demands.

The Keystone Telephone Company of Philadelphia, Pa., has reported its net earnings for the calendar year ended December 31, 1903, as $230,548, or twice the amount required to pay a 5 per cent. dividend on the $2,500,000 preferred stock.

The Sunset Telephone Company has found it necessary to construct a new line from San Diego to Corona, Cal., 100 miles distant. The line has been completed as far as Pala, 45 miles south of Corona.

The Oneonta, N. Y., telephone exchange now has 1,000 subscribers. A new switchboard has lately been installed.

The New York Telephone Company has opened a new telephone exchange at 350 West 17th street, known as the Chelsea.

Uses One Wire for Telephone and Telegraph.

H. C. Todd, of Maryville, Mo., manager of the Hanamo Telephone Company, has perfected an apparatus by which it is claimed that an ordinary telephone wire can be used for both telephone and telegraph service purposes at the same time. He has confined his operations to a long-distance wire extending from Maryville to St. Joseph. His experiment has proved practical, and for two days the line has been doing the double work.

The Hilton, N. Y., Telephone Company, owned and operated by a number of the citizens of the town of Hilton, has had a remarkably successful year. The company was organized a little over a year ago by several enterprising business men of the town, who felt that Hilton should be provided with adequate telephone facilities. Business was begun with only 22 subscribers. Many new 'phones were soon installed, until now nearly every residence and store in Hilton is provided with its telephone. Lines have been run out into the country and numerous farmers have availed themselves of the opportunity to establish telephone connections with the village. The Hilton Company has offices at Parma Center and Parma Corners.

The Madison County Gas & Electric Company has purchased part of the poles and wires of the Oneida, N. Y., Telephone Company, and the work of dismantling the poles down town has been commenced. The rest of the poles of the Oneida Company have been purchased by the Central New York Telephone & Telegraph Company.

Within a short time Lincoln, Neb., will be equipped with one of the most modern telephone exchanges in the world. The Nebraska Telephone Company will install in its Lincoln office improvements costing more than $100,000, principal of which is a $55,000 central energy switchboard with a capacity of nearly 10,000 telephones.

Lima, O., business men are said to have purchased the controlling interest in the Lima Telephone Company, which was owned by the Federal Company. The negotiations have been put through by F. S. Dickson, of the Federal Company.

At a recent meeting of the stockholders of the Warwick Valley Telephone Company at Middletown, N. Y., another semi-annual dividend of 2¼ per cent. was ordered paid to stockholders.

The Maple Valley Telephone Company of Iowa will expend $2,000 in improvements and extensions.

Telephone Incorporations.

The Beekmantown Telephone Company, Clinton County, Beekmantown, N. Y. Capital stock, $1,000. Directors: David Chellis, of Point Au Roche; George Deloria and W. P. Walker, Beekmantown.

The Masonville Telephone Company, Masonville, N. Y. Capital stock, $3,500. Directors: D. O. Smith, W. E. Bogart and H. S. McKinnon of Masonville.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Buffalo, N. Y.—The trustees of this city and County Hall have asked the county supervisors for the installation of an electric lighting plant.

Camden, N. Y.—This town is to set up an electric light plant of its own; $40,000 bonds have been issued to establish a plant.

Canton, Mo.—State Auditor Albert O. Allen, recently registered $10,000 worth of electric light bonds for this city.

Charlestown, Ind.—Mayor E. T. Runyon states that the contract for building a $6,000 electric plant here has been let to C. R. Hay, and the city has given him a 10-year contract for light.

Chillicothe, Mo.—The Merchants' Electric Light Company has raised nearly $25,000 for installing its plant.

Clifton Springs, N. Y.—This village is contemplating building an electric light plant.

Comanche, I. T.—The Comanche Electric Company is in the market for wire, insulators, cross arms, pins, etc., for the electric light plant. Address W. M. Diehl.

Downey, Cal.—A company in which A. L. Ball, T. R. Crawford and others are interested will erect a new electric light plant.

Elmer, N. J.—The Foran Electric Light Company, which has a franchise here, has asked the council to take action on the location of its plant in the borough.

Fort Branch, Ind.—The town board will soon grant a franchise for electric lights to Polk & Genung.

Frederic, Mich.—This town is to have an electric light plant soon.

Laconia, N. H.—The Laconia Electric Lighting Company has increased its capital stock from $45,000 to $60,000.

Meadville, Mo.—The question of an electric lighting plant is being agitated here.

Modesto, Cal.—Charles Tulloch, manager of the Stanilaus Milling & Power Company, states that just as soon as a franchise is granted for an electric lighting and power system in this city, active work will begin on the construction.

Monongahela, Pa.—The council has been considering an offer of Spencer Brothers to build an electric light plant here.

Newtown, Pa.—This village is to have electric lights in the near future.

Penn Yan, N. Y.—The village electric light committee will secure figures on cost of dynamos and other machinery and improvements for the electric light service.

Pinconning, Mich.—The common council has taken action toward procuring an electric light plant.

Rockingham, N. C.—Arrangements are reported to be under way for the establishment of a 25,000 hp. electric plant here. Alex. Page is said to be interested.

Sonestown, Pa.—The citizens of this town and Muncy Valley are trying to secure electric lights for their villages.

St. Peter, Minn.—M. B. Johnson & Co. are to install a dynamo in their factory for power and electric lighting purposes.

Sturgeon Bay, Wis.—The city council has purchased the electric lighting plant from Adolph Hamacek for $19,000.

Tamms, Ill.—The Illinois Milling & Elevator Company, incorporated with a capital of $50,000, will do milling, and furnish electric light and power. Oscar T. Tamms, Joseph Mayer, Jr., and others are interested in the concern.

Troy, O.—The Western Ohio Traction line has made a proposition to the people of Sidney to furnish power for lighting homes and running machinery.

Vicksburg, Miss.—The Vicksburg Railway & Light Company, of which S. S. Bullis is president, will increase its lighting capacity, but has reached no definite decision yet as to how this shall be done.

Wisner, Neb.—The matter of installing an electric lighting plant here has been revived.

Watertown, Tenn.—Plans are under discussion to erect a new electric light plant here.

STREET RAILWAYS.

Albert Lea, Minn.—The Inter-State Electric Railway Company is planning an electric railway from Central Minnesota.

Altoona, Pa.—A project of Philadelphia capitalists is under way to construct a trolley line from this city to Bedford by way of Loys Gap, where the Bedford Water Power & Electric Company is building one of the largest power plants in this section.

Atlantic City, N. J.—The city council has granted a franchise for a trolley line on Virginia, South Carolina and Adriatic avenues to the Central Passenger Railway Company, which is controlled by local capital. The line is to be built within one year.

Baltimore, Md.—A. J. Carr says he has information to the effect that the proposed electric railway will be built from here to Frederick.

Colorado Springs, Col.—General Manager C. W. Sells of the cog road has announced that Eastern electrical engineers are at work perfecting a new storage battery which is his own invention, and which is to be utilized in electrifying the system next spring or summer. The estimated cost of the installation is $225,000.

Connersville, Ind.—The Ohio & Indiana Traction Company is seeking an entrance to this place.

Findlay, O.—Mayor C. B. Metcalf and Drs. W. W. and W. H. Drake, of this city, and C. M. Bailey, of Toledo, are the incorporators of an electric road to be known as the Lake Erie Traction Company. The capital is $100,000.

Fond du Lac, Wis.—J. P. McMullen, of Chilton, is interested in the building of an electric line from here to Manitowoc.

Frederick, Md.—The Catoctin Electric Railway Company is the name of a new concern being formed here, to build an electric trolley system between this city and Middletown. C. R. Tottlemyer is interested.

Gloversville, N. Y.—The Fonda, Johnstown & Gloversville Railroad Company has purchased the property of the Adirondack Lakes Traction Company, consisting of the trolley line leading from Gloversville to Mountain Lake, and all the accoutrements, hotels and pavilions at the lake. The road will be run independently of the Fonda, Johnstown & Gloversville systems. John Shanahann has been elected president, Lyman K. Brown vice-president, and E. H Stechel secretary. The road will be placed in first-class condition, and many improvements are planned at Mountain Lake.

Lafayette, Ind.—The Fountain Warren Traction Company, which was promoted two years ago for the construction of an electric railroad from Danville, Ill., to this city, is now assured of the success of the project.

Marshalltown, Ia.—A franchise was lately granted to the Marshalltown Electric & Interurban Railway Company,

Nashville, Tenn.—C. M. Henley, of Columbus, is contemplating building an electric railroad from this city to McMinnville.

Newport, R. I.—The Newport & Providence Railroad Company will erect a power house early next spring.

Omaha, Neb.—H. C. Avery, chief enginer of the Council Bluffs, Tabor, Southern Electric Railway Company has started on a survey of the route by which the company proposes to enter Council Bluffs.

Pittsfield, Mass.—The Western Massachusetts Electric Railway Company has announced that connecting lines between Westfield, Mass., and Hudson, N. Y., were to be built, connecting the Hudson River with the Connecticut River Valley, and furnishing a connecting link in the chain of electric roads between Boston and the Hudson River.

Richmond, Ind.—If the plans of the men back of the Columbus, Greensburg & Richmond Traction Company materialize the company will have one of the greatest systems of trolley lines in the world. The plans contemplate not only a line from Columbus through Greensburg to this city, but also several long branch lines.

Richmond, Va.—The Passenger & Power Company will build an electric railway between this city and Ashland.

Sterling, Ill.—The Rock River Traction Company has been granted a right of way along the south side of the Sterling and Morrison road.

South Bend, Ind.—Construction work will be begun this month on the Chicago-Indiana Air Line electric road between here and Michigan City, where the company has eight miles of grading finished.

White Plains, N. Y.—An effort is being made to obtain permission to build a trolley line from here to Port Chester over a route which has long been opposed by residents and property owners.

POWER PLANTS.

Lindsay, Cal.—McLees Brothers and William McIndo intend to install an electric-power pumping plant on their property west of town.

Loomis, Wash.—The Plamer Mountain Gold Mining Tunnel Company is to erect an electric power plant here.

Rock Island, Ill.—There is a plan to harness the Mississippi Rapids here and use the water power. It is proposed to build a dike 500 feet from the north shore, 20 miles up the river, and get a 15-foot fall which will develop 20,000 hp.

Vicksburg, Miss.—It is stated that S. S. Bullis, of this city, contemplates erecting an electric power plant at Waltersville, a suburb of his city.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅝@12¾c; Lake 12¾@12⅞c.; casting, 12½@12⅝c.

The Buffalo (N.Y.) Frontier Terminal Railroad Company has been incorporated with a capital of $3,000,000.

At the annual meeting of the Citizens' Passenger Railway Company of Philadelphia, held Monday last, the old board of directors was re-elected.

The Bullock Electric Company is making elaborate arrangements for its annual salesmen's meeting, which takes place in Cincinnati January 25.

The use of electrical power on the New York elevated railway has reduced the percentage of expenses to earnings from 51 per cent. to 42 per cent.

It is reported that the quarterly dividend due on the North Chicago Street Railway Company on January 15 will be 1¼ per cent. instead of 2 per cent.

The Edison Electric Illuminating Company, it is stated in Boston dispatches, has acquired the Somerville (Mass.) Electric Light Company, the consideration being $577,000.

The United Traction Company of Albany, N. Y., has declared the regular quarterly dividend of 1¼ per cent., payable February 1. Books close January 21 and reopen February 2.

It is reported from Carlisle, Pa., that negotiations are under way for the consolidation of all the trolley roads in the Cumberland Valley under the name of the Valley Traction Company.

The Prismatic Electric Manufacturing Company of New York has been incorporated with a capital stock of $200,000. The directors are M. E. Wooster, C. E. Bieyer and Leopold Wallach, New York.

The Electric Company of America (Philadelphia) has declared the regular semi-annual dividend of 3 per cent. payable January 30 to stock of record January 20. Books close January 20 and reopen February 1.

The General Electric Company has proposed a reduction in wages of molders employed at the Schenectady plant, amounting to about 33⅓ per cent. They have refused to accept the reduction and a strike is talked of.

The city council of Cleveland, O., on Monday night passed the three-cent ordinance drawn at Mayor Johnson's dictation some time ago. By its terms three-cent fares will be required on every line within the limits of Cleveland.

The Hudson River Electric Power Company recently filed a mortgage in the Saratoga County (N. Y.) clerk's office to the Knickerbocker Trust Company of New York, to secure an issue of 5,000 $1,000 gold coupon bonds, bearing 5 per cent. interest.

There is annouced a combination of two wireless telegraph companies, with a combined capital stock of $15,000,000. The De Forest and the International Companies have been consolidated. The name of the new company is the American De Forest Wireless Telegraph Company.

The bondholders' committee of the Michigan Telephone Company, with counsel, are now in conference with Mr. N. W. Harris, in New York, formulating a plan for the operation of the Michigan Telephone property purchased by the bondholders through Mr. Harris in Detroit some weeks ago. The property, valued by experts at about $10,000,000, was sold under the hammer and went to the bondholders at $4,100,000. By financiers it is considered as an excellent bargain.

ELECTRICITY.

VOL. XXVI. NEW YORK, JANUARY 20, 1904. NO. 3.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries...................... 3.00
Single Copies......................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

CONTENTS.

EDITORIAL NOTES.

A Good Bill. It is about time that something was done to eliminate the dangers of the third rail on the elevated roads in Greater New York. An attempt is to be made to do this "something." A bill is about to be introduced in the Legislature at Albany which, if it becomes a law, will oblige transportation companies to improve their systems. We say "if" it becomes a law, for every effort will be made by transportation companies in the State to have it tabled indefinitely. The bill as it is drawn empowers the State Railroad Commissioners to compel railroad companies to carry out the recommendations of the board. As the law now stands the Commissioners can order changes, but the companies may make them or not as they see fit.

It is said to be the intention of the State Railroad Commissioners if the bill becomes a law to require the Manhattan and the Brooklyn Rapid Transit Companies to devise a safer method of using the third-rail system. Such being the case, it is to be hoped the bill will not find its way into one of the numerous pigeon holes that abound in Albany.

Will Radium Cure Cancer? From time to time in past years, we have referred in these columns to various alleged electrical cures for cancer. Right here it might be in place to state that up to the present no absolute cure for that dreaded disease has been discovered, although in certain cases treatment by X-rays or by Dr. Finsen's process tends to give relief and retard the spread of the disease.

So far the cases treated have been external ones, but according to Dr. William James Morton it may be possible in the near future to treat internal cancers. This may be made possible through the medium of radium.

Before the Technology Club in this city Dr. Morton last week spoke at considerable length on this subject and explained several discoveries made by him. At the beginning Dr. Morton warned his audience that he did not contend that he had discovered the cure for cancer. He urged on them that he merely had reached certain results with the aid of radium, which he felt justified him in taking his colleagues into his confidence in order that further experiments may be made along the lines he has adopted.

Stripped of all its technicalities, the treatment Dr. Morton has given his patients consists of an outward application of radium to the affected parts, after the body has been prepared inwardly by administering fluorescent fluids which, under the action of the radium, produce ultra-violet radiation.

In other words, by the combination effected through the interior and exterior treatments, what amounts substantially to sunlight is created within the body, and the treatment is the same as though the actual light of the sun was concentrated upon the diseased portion of the body.

At the meeting referred to above Dr Morton explained the reasons and method of his treatment as follows:

"It is well known that certain solutions which may be used as medicines are rendered fluorescent by radium radio-activity and by the X-ray. They are quinine, aesculin fluorescin and orcin. The fluorescence of quinine, aesculin and orcin is of a most beautiful blue-violet color, and where the violet end of the spectrum is found there is also found above it the ultra-violet radiation. Both are capable of these chemical effects, which are usually

known as the effects of the actinic rays of the spectrum.

"It occurred to me that I might combine the properties which the X and radium rays have of penetrating human tissue with these facts of fluorescence, and thus establish a system by means of which we could flood a given organ or seat of disease with a fluorescible fluid used medically and at the same time, by turning the X or radium ray upon this region, set up at desired area actinic radiation, thus bringing to bear the ultra-violet ray in a manner which could not be attained by any application of it from the outside.

"This plan is perfectly feasible, I have already practiced it for some time."

There would seem to be little doubt but what the peculiar and wonderful characteristics of radium will ultimately find its greatest sphere of usefulness in medicine and if any genius can adapt this new element to the cure of cancer he will have conferred upon humanity a benefit for all time.

* * *

Electrical Smelting of Iron Ore. Smelting iron ore by means of electricity has been successfully accomplished in several countries in Europe, namely, in France, Italy and Sweden, and also to a limited extent in the United States.

The Ottawa Government is now looking into the feasibility of this process of reducing ore with a view to its introduction in Ontario and Quebec.

In his recent presidential address before the Canadian Institute of Electrical Engineering, Mr. Robert Raye Gray, the president of that body, made the following reference to the electrical reduction of iron ores:

"Another valuable process, which has made considerable progress during the past year, is the reduction of iron ores by means of the electric furnace. At Livet, in France, the process is in practical operation, generators of 1,200 hp. each giving ingle-phase currents at 30,000 amperes eing employed. The output is 12 tons of teel per day. At these works ferro-silicon is also made from quartz, scrap iron and coke, at less cost than that of smelting, and copper pyrites is reduced to copper and iron sulphides rich in copper and ready for the smelting process. Steel of high quality is similarly produced in Sweden at the rate of 1,500 tons per annum. With the Stassne process, the expenditure of energy is said to be 3,000 hp. per ton of iron."

The Ottawa Government is now examining into the electrical process of smelting iron because in certain localities of Ontario and Quebec there exist extensive iron ore deposits which cannot be successfully worked owing to a lack of adjacent or available coal supplies. It is thought that if the energy now wasted in many waterfalls throughout the interior of the country can be used economically in smelting the ore it will open up a splendid field for profitable enterprise. Such should be the case providing the water power it is proposed to utilize is not too far distant from the ore deposits. At the present time, however, the test of profitable operation will be severe owing to the low price of iron and steel.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

At the next meeting of the Chicago Electrical Association the members will vote on a resolution to affiliate with the Western Society of Engineers.

The Technology Club of this city, composed of the alumni of the Massachusetts Institute of Technology, will give a dinner February 5 at the University Club, at which "liquid sunshine" will be served. Dr. Morton, the discoverer of "liquid sunshine," has given the formula for making this liquid, which in a capsule will be placed at each plate with a glass of water. The room will be darkened, each man will drop the capsule into his glass of water, and will make his own "liquid sunshine," with a tube of radium in this liquid, which will be drunk to Alma Mater.

The experts who witnessed the experiments in wireless submarine signaling conducted last Thursday between New York and Boston are so well pleased with the results that the Government will probably equip many more of the lightships with the submarine bells, providing the owners of steamship lines will put the supplementary apparatus on their boats. Universal adoption of the system would greatly diminish the danger of collision or running aground during fogs, as it was demonstrated during the recent tests that the warning sounds from submerged bells could be heard plainly for at least seven and a half miles.

The Marconi Wireless Telegraph Company is not operating commercially upon land or from shore to shore as yet, but has been successful in its recent experimental operations. Daily communication is now held between Cape Cod and Glace Bay stations, a distance of 700 miles, but the Poldhu station in England has not been equipped as yet to permit of transatlantic communication.

A cable dispatch from Paris says that M. Curie's non-acceptance of the Legion of Honor decoration seems to have encouraged more substantial recognition. One of the best equipped laboratories in the Pasteur Institute has now been placed at the disposal of the savant and his wife. Moreover, a bill has been introduced in the Chamber of Deputies by M. Gerault-Richard opening a special credit of 150,000f. ($30,000) to permit M. Curie to continue his researches. There is every prospect that the bill will be passed by a unanimous vote.

There will be a reunion of members of the Society of Mechanical Engineers on Tuesday, January 26, at 8:30 P. M., at the Society House, 12 West 31st street, New York City. The purpose of this reunion will be to listen to an address by Mr. John A. Brashear, of Pittsburg, entitled, "The Evolution of Measurements." The address will be illustrated.

Tests of an invention by Prof. Michael I. Pupin, of Columbia University, for "strengthening sound waves" are being made by the New York and New Jersey Telephone Company. Thus far results are said to be satisfactory. The system discovered by Prof. Pupin provides for coils wound on wire at regular intervals on a circuit. It has been installed on special underground lines, extending to Kingsbridge, in Manhattan, from New York to Elizabeth and to points on Long Island.

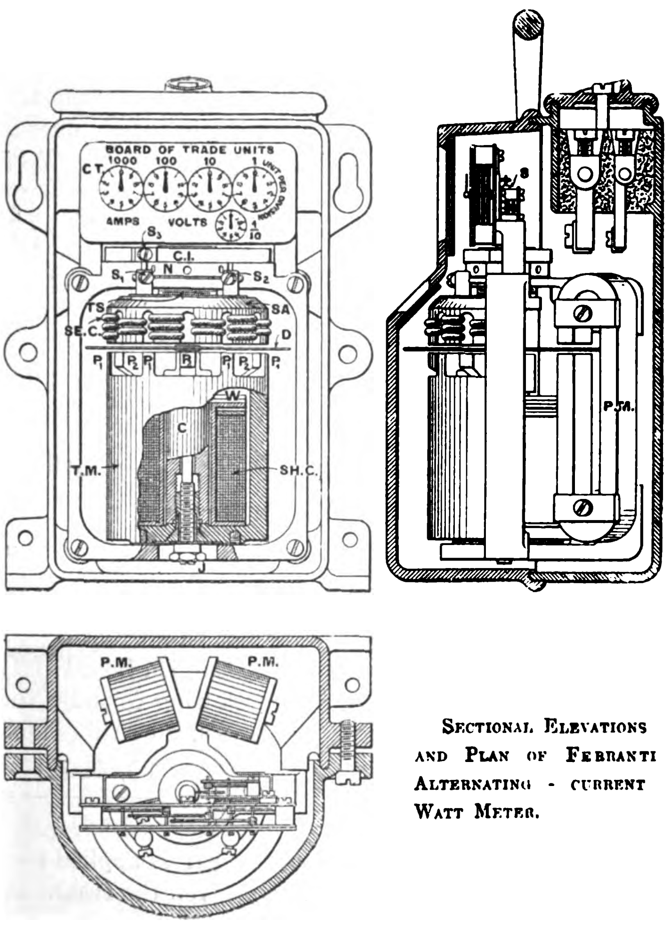
The annual automobile show in New York City began on January 16 at Madison Square Garden and will last one week. More than 185 firms have been accommodated in the distribution of space. The exhibition is held under the auspices of the Automobile Club of America, the National Association of Automobile Manufacturers and the Madison Square Garden Company.

Secretary Wilson informed President Roosevelt last Friday that scientists of the Department of Agriculture had perfected a system of wireless telegraphy. It differs from both the Marconi and De Forest systems. It is now in successful operation between San Francisco and the Farallone Islands, 27 miles. The new system is used by the Weather Bureau and every step in its development is being covered by patents.

FERRANTI ALTERNATING CURRENT INTEGRATING WATTMETER.*

A new alternating current wattmeter possessing certain novel features has recently been brought out in London. The meter is of the induction motor type, measuring accurately the energy consumed on an alternating current circuit, whether the load is inductive or non-inductive; and it is essentially a practical, commercial instrument, the energy being recorded directly in Board of Trade units, and no multiplier or constant is necessary. The accompanying illustrations show clearly the construction of the meter, and indicate the simplicity of its parts.

The aluminum rotatable disk D, mounted on the spindle S and geared to the train of wheels CT actuating the index hands, serves the double purpose of an armature receiving the driving torque of the meter coils and also the retarding torque of the permanent magnets PM. One shunt coil, SHC, placed round the coil C of a special tubular electromagnet, TM, constitutes the shunt system. The core of this magnet has three outward radial poles, P_2, alternating with four inward radial poles, P_1, from the shell or tube of the shunt magnet, the plane of these poles being horizontal and parallel to the disk; this tubular magnet is placed below the disk. It is well known that, in the case of the induction motor type of meter, it is necessary that the shunt circuit should be very inductive, and in this connection a special tubular magnet is found most suitable, no choking coils, secondary circuits, resistances or compensating coils being required. The number of electrical connections is thus reduced to a minimum, and the possibility of trouble therefrom considerably reduced. The series system consists of a slotted armature, SA, above the disk, the series coils SEC being wound in these slots. A wave-form of winding is used, somewhat similar to the winding adopted by Mr. Ferranti for his alternators in 1884; it will be noted that the slots of the series armature are almost directly above the poles of the tubular magnets.



SECTIONAL ELEVATIONS AND PLAN OF FERRANTI ALTERNATING - CURRENT WATT METER.

If the shunt circuit be sufficiently inductive, the eddy currents produced in the disk by the shunt field will be in phase with the impressed EMF. These eddy currents are acted on by the series field, which is in phase with the load current, giving a driving torque on the disk proportional to the EMF. of the circuit multiplied by the amperes and by the cosine of the angle of lag of the main current behind the EMF., this being the true watts supplied to the circuit through the meter. The retarding torque due to the permanent magnets is proportional to the speed, and the disk therefore revolves with a speed which is proportional to the watts. If the series and shunt magnetic systems could be made exactly symmetrical and placed relatively to one another in a symmetrical position—i. e., the slots of the series magnet exactly above the shunt poles—then the disk would not rovolve when the shunt coil alone is energized, and the meter would read low at the small loads owing to the friction of the train and spindle bearings. For the purpose of compensating for any dissymmetry in the magnetic system due to small irregularities in material, workmanship and pivot friction, it is necessary to have some adjustment which gives a driving torque when no current passes through the series coil, this driving torque being insufficient in itself to cause rotation of the disk and train. In many other meters, special grooves, pole extensions or coils are required, but it is an important feature in the Ferranti design that no additional windings or parts are necessary, as the series magnet is simply turned about the axis of rotation of the disk to the necessary extent to effect the required compensation; for if the series magnet is displaced clockwise, the disk will tend to revolve anti-clockwise. But if, on the other hand, the series magnet is put to the other side, the disk will tend to revolve clockwise. Hence it will be seen that it is possible to leave the series magnet slightly out of center in the direction which gives a slight torque on the shunt alone, and this can be very accurately adjusted to compensate for pivot friction or for any dissymmetry in the magnetic circuit met with in manufacture.

The adjustment can be most accurately made, and the meter can be calibrated or adjusted by the simple action of slightly altering the relative positions of the shunt and series magnets, and this is done by means of the two screws S_1 and S_2. The driving torque with the shunt alone, even with the maximum possible displacement of the series armature, is extremely small, and as it will be noted that the armature is fixed by a powerful clamp, Cl, and the two screws S_1 and S_2, the possibility of the meter developing any tendency to creep on the shunt is very remote. The constant of the meter is also readily adjusted by lowering or raising the series armature by means of the nut N on the threaded spindle TS, the effect of this being to strengthen or weaken the action of the coils, and after adjustment the series magnet is securely fixed by means of the strong clamp Cl and the screw S_3. On all conditions of circuit, inductive or

*From the "Electrician," London.

non-inductive, on overloads up to 50 per cent., and under variations of voltage to 50 per cent. above or below the normal, the meter is very accurate, and it is also practically independent of variations in frequency, wave form or temperature. Every meter is calibrated to the following limits of accuracy: $1\frac{1}{2}$ per cent. from one-tenth to full load, and $2\frac{1}{2}$ per cent. from one-twentieth to one-tenth load. The accuracy is not affected by short-circuit through a fuse of double the capacity of the meter. It is said that a 10-ampere meter starts well with 0.05 ampere, and can be relied upon to register with a 250 volt 8 cp. lamp. The losses in the meter are very small, and the efficiency is consequently high; in a 10 ampere 200 volt 100 periods instrument it is claimed that the losses in the shunt circuit are not above 1.7 watts, and the series loss at full load does not exceed 0.8 watt. Only 0.015 ampere is required in the shunt. All Ferranti alternating meters are tested to withstand a pressure of 1,000 volts alternating, applied between windings and case. For convenience in testing, all meters are calibrated to run at a standard speed of 40 revolutions per minute at full load, the standard voltages for calibration being 100, 110, 120, 200, 220 and 240. For intermediate voltages the nearest standard is adopted, this making no difference in the accuracy of the meter.

The terminal box is specially designed to facilitate testing, the shunt being connected to a fourth terminal, which can readily be disconnected from the main terminal, allowing the shunts of several meters to be placed in parallel on the voltmeter leads, and avoiding unnecessary opening of the cases. All meters are fitted with a one-tenth unit train on front dial for facility in testing. The meters are fitted with removable jeweled brass settings, J, which enables a defective jewel to be easily replaced by a new one at any time without altering the calibration of the meter, all parts being interchangeable.

COLLAPSING PRESSURE OF TUBES AND FLUES.

ARTICLE II.

BY W. H. WAKEMAN.

Applying the last figures in Article I to a 3 inch tube 4 feet long shows that the collapsing pressure is 655.6 pounds, or practically twice as much as for the same tube 16 feet long. In this case the collapsing pressure does not vary directly with the length but nearly with the square root of it. The first glance at this formula is sufficient to discourage some readers, but investigation shows that while it is long it is not difficult to apply, as the process is very simple.

D. K. Clark gives the following formula, but does not recommend it for flues more than 6 inches in diameter:

$$\left(\frac{112,000}{D} - 12,000\right) \times t = P.$$

D = diameter in inches.
t = thickness in decimals of an inch.
P collapsing pressure in pounds.

This gives the collapsing pressure for tubes and flues as follows:

3 inch	tube,	2,761	pounds.
4 "	"	2,144	"
6 "	flue,	1,099	"

It cannot be applied to a 12 inch flue because the quotient found by dividing 112,000 by 12 is less than 12,000, therefore the operation fails.

A flue 9 inches in diameter is the largest to which it can be applied, and if we assume the thickness to be .2 inch the collapsing pressure is 67 pounds. A formula which can be applied to a 9 inch, but cannot to a 10 inch flue, is of doubtful value to say the least.

The same authority presents the following for our consideration and adoption:

$$\left(\frac{50,000}{D} - 500\right) \times t^2 = P.$$

D = diameter of flue in inches.
t = thickness in decimals of an inch.
P = collapsing pressure in pounds.

Applying this to the tubes and flues above mentioned gives the value of P for comparison:

3 inch	tube	.109	inch	thick,	192	pounds.
4 "	"	.134	"	"	215	"
5 "	flue	.165	"	"	213	"
12 "	"	.229	"	"	192	"
20 "	"	.32	"	"	204	"
40 "	"	.5	"	"	187	"

It will be noted that the two preceding formulas do not bring the length of tubes and flues into consideration at all, and this is going to the other extreme. His idea is that the length has no more effect on the collapsing than it does on the bursting pressure, which is contrary to the conclusions arrived at by other engineers. While commenting on this idea he says very plainly that the length of tube is the least influential factor, and of very small value, except for very short lengths, as practically all the resistance to collapse offered by plain tubes is supplied by the compressive strength of the material and stiffness of the tube. This is undoubtedly true, so long as the tube is kept perfectly round, but this is an important proviso, which cannot always be realized in practice.

From a large number of collapsed tubes he selects 21, which present a good assortment of lengths and diameters, and by plotting these results and drawing a curve through them, representing the average of the whole, the following formula is derived:

$$\frac{200,000 \times t^2}{d^{1.75}} = P.$$

t = thickness of flue in decimals of an inch.
d = diameter of flue in inches.
P = collapsing pressure in pounds.

The length is not taken into consideration, except in a statement which informs us that it varies from 18 to 40 feet.

At first it appears as if a formula based on the actual results of practical work would be more valuable than any other, but further consideration does not confirm first impressions.

Were all of these flues made of material of uniform quality? Were they all new, or had they seen varying terms of service which would leave them in different conditions? Was the thickness uniform, or was it reduced in places by legitimate wear and corrosion? If one was new and in good condition, and another old and weak, is it proper to take the average of them and adopt it for general use?

Until these questions are answered we have a right to place our own valuation on the formula. The variation in length from 18 to 40 feet shows that there is a chance for this factor to effect the result, and to strike an average in this respect may not be correct.

The English Board of Trade has adopted the following formula for the safe working pressure of tubes and flues:

$$\frac{90,000 \times t^2}{(L+1) \times d} = P.$$

When it is applied to the examples already given the results are as follows:

3 inch	tube	.109	inch	thick,	21	pounds.
4 "	"	.134	"	"	24	"
6 "	flue	.165	"	"	24	"
12 "	"	.229	"	"	23	"
20 "	"	.32	"	"	27	"
40 "	"	.5	"	"	33	"

Applying this to a 3 inch tube 4 feet long gives a safe working pressure of 71 pounds, and for a 40 inch flue 5 feet long it is 94 pounds.

The effect of (L + 1) in this formula is to give a tube 16 feet long less than four times as much pressure as would be allowed on one 4 feet long, but it does not vary the pressure directly with the length, nor yet with the square root of the length,

therefore these two extremes are avoided.

The apparent constant 90,000 may be varied to suit conditions, where the tube or flue is not perfectly round or the workmanship is defective. It may be taken as low as 60,000.

There is a proviso to the effect that pressure on tubes or flues coming under this formula shall in no case exceed the result obtained by the next formula:

$$\frac{8,000 \times t}{d} = P.$$

t = thickness in decimals of an inch.
d = diameter in inches.
P = safe working pressure.

The limit of pressure allowed is much above the results secured by the preceding formula, as the following table demonstrates:

3 inch	tube,	291 pounds.
4 "	"	268 "
6 "	flue	220 "
12 "	"	153 "
20 "	"	128 "
40 "	"	100 "

These pressures are not excessive when viewed from a practical standpoint.

Before passing on to other formulas a general review of those already given are in order. Taken as a whole they are unsatisfactory, because some of them were not intended for use in relation to 3 and 4 inch tubes, but it is not so stated in connection with them, therefore they are taken and applied as found.

Others are apparently designed for comparatively short and large flues, but it is not always so stated.

It is practically impossible to devise a formula that will be satisfactory for small, long tubes and short, large flues.

ELECTRICAL SPEED INDICATORS —SOME UNSUCCESSFUL ATTEMPTS.*

BY A. S. CUBITT.

A short time ago attention was called to the advantages of making public any unsuccessful experimental work, both with the idea of calling attention to the difficulties which beset the path of the experimenter, and also to save later workers the necessity of finding out by unhappy experience the infeasibility of working on certain apparently hopeful lines. With this idea in view, a description of certain experimental and proposed forms of speed indicator which have been devised by the author, and which have been up to the present more or less unsuccessful for reasons which will be stated, may be of interest. Some of the earlier attempts were crude in the extreme, and never proceeded very far even in the experimental stage, but it will be noted that all through one special principle has been adhered to in the main. One of the earliest attempts consisted in interposing a make and break in a circuit comprising an ammeter, a battery, and a resistance, but, as might be expected, it was found that beyond a very small range the value of the current remained stationary for all speeds owing to the fact that the duration of the contact varied inversely as the number of contacts per second, so that the average duration of contact per second remained the same.

It was very apparent that to operate a speed indicator on this principle it would be necessary that the apparatus must be so arranged that the amount of energy imparted to the moving part of the indicator per contact, or its equivalent, must remain a constant. With this idea in mind a mechanical model embodying this principle was devised and built, and proved the correctness of this theory. Mechanical considerations, however, rendered this impracticable, as may be seen. Referring to Fig. 1, a flywheel was con-

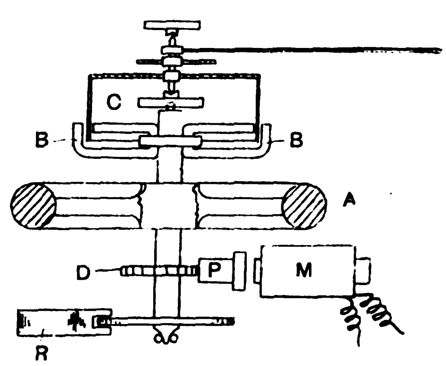


FIG. 1.

structed and pivoted on ball bearings so as to revolve very easily. To this flywheel was attached a set of magnets, B B, designed when revolving to impart a torque to a copper cylinder, C, embraced by them, this torque being proportional to the speed at which the magnets revolved. To the lower part of the flywheel was attached a racket wheel, D, and a copper brake disk revolving between the poles of the magnet, R. The ratchet wheel was arranged to be operated as a pawl, which was normally held clear, but which could be pulled into place by a magnet, M, and which when let go would by means of the spring attached to it impart an impulse to the flywheel. Now, assuming that the amount of energy imparted to the flywheel per kick remains constant, the greater the number of kicks per second the greater the energy imparted to the flywheel and the greater the speed. If a copper brake disk were attached to the flywheel, the speed attained would be proportional to the energy imparted—i. e., to the number of kicks per second. With a simple contact on the transmitter a speed of flywheel proportioned to the speed of the transmitter contact could be obtained, and a means of indicating the speed by indicating the torque in the copper cylinder secured. It was found, however, that owing to the fact—which had been overlooked—that the energy imparted per kick was dependent on the speed of the flywheel at any moment, falling off as the speed went up, the speed curve turned over very quickly, and cut down the range of the instrument greatly. By substituting for the copper brake disk a hysteresis brake having a practically constant back torque independent of speed, the curve was straightened out and a fairly satisfactory instrument attained. Owing to the very high speeds necessary to operate steadily, the life of the instrument was barely 24 hours, and on purely mechanical considerations was abandoned.

At this time the principle of imparting energy to the moving part of the indicator at a rate proportional to the speed to be indicated was shelved for a time, as the difficulties due to the variation of the pressure on tramways—for which purpose the instrument was destined—were considered too great, and experiments were made on a very different type of instrument. A pair of magnets were mounted on a frame which was geared to the axle of the car whose speed it was required to indicate, and this frame and magnets caused to revolve at a speed proportional to the speed of the car. These magnets, which were very powerful, embraced a copper disk controlled by a stiff spring. This disk, under the action of the rotating magnets, took up different positions according to the speed, and by means of a small arm, made contact on one or other of a series of small contacts connected respectively to a set of electromagnets arranged radially in a cast-iron case forming the indicator. A soft-iron needle pointed to the electromaget excited and carried a pointer indicating the speed corresponding. The disadvantages of this instrument were, amongst others, the unreliability of the contacts, the number of wires required, the possible errors of indicating due to the few points available, the method of operating requiring a large torque in order to allow the friction of the moving contact to cut a small enough figure.

After some minor experiments the orig-

*From the "Electrical Engineer," London.

inal principle above referred to was returned to, this time with greater success. After many disappointing experiments it was concluded that a reliable contact, giving a duration of contact independent of the number of contacts per second, was impracticable, it being assumed that this style of contact, or its equivalent, was necessary to give the desired result. In order to obtain this result an entirely novel idea was evolved, which had the merit of being extremely simple. Referring to Fig. 2, it will be seen that an

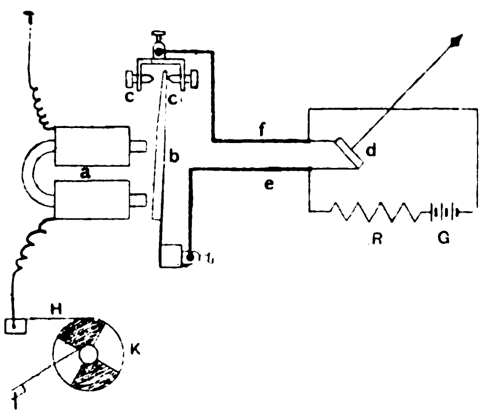

FIG. 2.

auxiliary circuit, comprising a battery, a resistance, and an indicating ammeter, was required. The terminals, f, e, of the moving coil of the instrument, d—in the experiments a Weston milliammeter—were connected by thick wires to the armature, b, and the contact screws, $c c_1$, so that normally the moving coil was short-circuited and the current flowing through the circuit was directed through the armature, b. The battery, G, provided a source of current which was kept to a low value by means of the resistance, R. On the axle whose speed it was required to indicate was placed a contact, K, on which rested a brush, H, and the circuit was so arranged that on revolving the contact, K, the armature, b, would be oscillated between the stops, $c c_1$, at a rate proportional to the speed of the contact, K. The time, however, taken to move the armature from c_1 to c or back would be a constant (the electromagnet being designed to be saturated at voltage below the normal) so that the time the circuit, e, b, c, f, was open each oscillation would be a constant. During this period the current would be free to flow through d, and this would receive a definite impulse. This moving coil was weighted so as to have a considerable mass, and the result was that it took up a definite position corresponding at any time to the number of impulses per second, and, therefore, to the speed required to be measured. This instrument proved quite satisfactory in laboratory operation, but the difficulties in keeping the current constant and the wear of the contacts, $c c_1$, made it unsuitable for practical use. Subsequent experiments evolved a method of doing away with the battery, and by making the contacts of hard steel the wear was sensibly diminished, but as the experiments leading up to these improvements were made on a more suitable type of instrument—which will be described later—no further description will be necessary here.

Whilst experimenting with this instrument with a view to stop the sparking at the contact, K H, which was made in the 500-volt circuit, a high-resistance shunt was connected across K H. This, whilst it considerably lessened the sparking, had the effect of preventing the armature being released when the speed exceeded a certain amount, and the observation of the naturally expected fact, that a considerably less current was required to hold the armature in place than to pull it over, led to the evolution of a novel type of instrument, embodying features which are not to be met with in any other type of apparatus. For want of a better name the principle of this instrument may be described as an "electromagnet ratchet." A reference to Fig. 3 will make this prin-

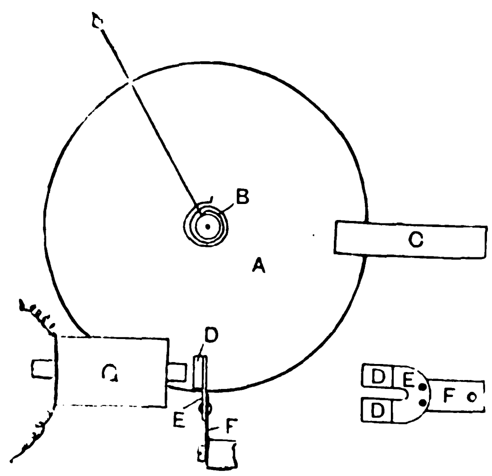

FIG. 3.

ciple clear. A copper disk, A, was pivoted in the center and constrained to remain in the zero position as shown by the spring, B; the movements of this disk were damped by means of the magnet, C. Embracing the disk was the armature, D D, made in two halves, connected by a non-magnetic bridge piece, E. This armature was kept in a definite position with regard to the disk by means of the spring, F. An electromagnet, G, was so placed that the armature, D D, formed part of this magnetic circuit, leaving a gap of about $\frac{3}{16}$ inch between its pole-pieces and the armature D D. This instrument was actuated by means of a simple make and break on the axle.

The operation was as follows: The electromagnet, G, was connected in series with a resistance and with the contact on the axle, and was supplied with current from the trolley wire. In order that the magnetic flux should be practically constant during any changes in the voltage of the circuit, the electromagnet was so designed that its core would be saturated at the lowest anticipated voltage. When the circuit was made, the armature, D D, was attracted and moved over to the pole-pieces. This movement did not take place, however, until the magnetic flux had risen to a fairly high value, and it will be noted that the whole of this flux had to pass through the portion of the copper disk which laid between the two halves of the armature, D D. Thus, when this armature moved over, it exerted a torque on the copper disk by virtue of the eddy currents generated, and moved the disk slightly forward. When the circuit through G was broken, the armature, D D, returned to its initial position by means of the spring, F. This, however, did not happen until the flux had died down to a minimum value, owing to the reduction of the air-gap, so that the torque exerted on the copper disk during the backward motion was very small compared with that exerted during the forward motion. The distance, therefore, that the disk moved back was less than the distance the armature moved back in proportion to the time interval between the successive movements of the armature—that is to say, in proportion to the speed at which the contact on the axle was being made and broken. The result was that the disk was projected forward by the impulses piling one on the other until such a time as the tension on the spring, B, was great enough to constrain the disk to move backwards at the same speed that it moved forward during one impulse—that is to say, until the pseudo torque imparted by the vibrating armature to the copper disk, A, was equal to the torque upon the spring, B. From this it is clear that for every speed of oscillation of the armature, D D, a corresponding definite angular position of the copper disk, A, with regard to its initial position would be found, and by means of a suitable pointer attached the instrument could be calibrated to read direct in miles per hour.

A full-sized working model of this instrument was built, and it was found that the operation followed exactly the lines anticipated, but, owing to the very small movement of the armature, the resultant torque was not great enough to be of any commercial value. In order to increase this torque it was found necessary to use as many as four armatures operating on the same disk, which made the instrument too bulky and complicated to be put for-

ward as a practical instrument. Attempts were made to increase the torque by using an iron disk, and although this was slightly more satisfactory, yet its behavior did not warrant its commercial production. Incidentally it was found that if the armature was allowed to come into mechanical contact with the disk, an apparently satisfactory instrument was obtained with an exceedingly large torque, and an instrument which, moreover, seemed to be perfectly reliable during the short time the trials lasted. But it was anticipated that it would not be possible to make an instrument on these lines which would stand the vibration which such an instrument would have to undergo, and which could be relied on as to its indications as soon as any appreciable wear has taken place.

Some time after this instrument was built a patent was taken out by two gentlemen well known to the author, involving this very principle, and which ap-

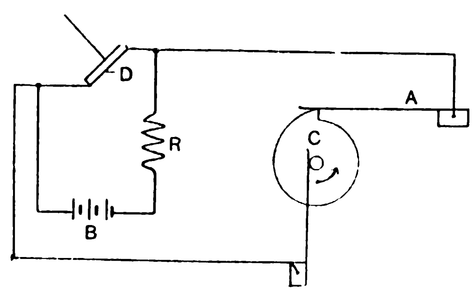

FIG. 4.

peared experimentally to be very satisfactory. This has since been dropped, however, on the same grounds of unreliable operation after any wear had taken place.

During these experiments a very interesting phenomenon was noticed with regard to the curious behavior of some sheet aluminum in a rapidly changing magnetic field. The bridge piece referred to, as connecting the two parts of the armature, was made of aluminum, and it was found that as soon as the armature was started, oscillating curious fern-like shapes semed to grow out from the metal, in a similar manner to that which has been observed when aluminum comes in contact with metallic mercury. A reason for this was never found out, and it would be interesting perhaps to some one with time to spare to investigate this.

Earlier in this article we referred to a method of doing away with the battery used with the type of instruments in which the moving coil of the indicating ammeter was short-circuited during part of the time the instrument was in use. The instrument about to be described was the one referred to, and it will be seen that the means used to render the indicators independent of any change of voltage will be equally applicable to either types. Referring to Fig. 4, D is the moving coil of a Weston type ammeter of very low capacity, B is a couple of cells of storage battery, R is the resistance. The coil, D, is normally short-circuited through the spring contact, A, resting on the cam, C, so that there is practically no current flowing through the coil, D. If the cam, C, is revolved in the direction indicated by the arrow, the spring, A, will rise to the highest part of the cam, as is shown, and then drop down again to the lowest. The time taken to make this drop will be the same whatever the number of times this happens in any given time, and with each drop of this spring the short-circuit of the moving coil, D, will be opened, and therefore current will be free to flow through this coil. We have, therefore, a definite impulse imparted to it in each revolution of the cam, C, and if the moving coil is considerably weighted as before, in order to give it a definite mass, it will be found that for each speed of the revolution of the cam, C, a definite resultant torque will be imparted to the coil D, due to the piling up of the impulses, somewhat in the same manner as in the foregoing instrument. This was the first idea of this method of operation, and in the experiments made it was found that this form of contact was absolutely reliable, provided it was made of sufficiently hardened steel, and provided also that the spring, A, was sufficiently hard and under constant tension, and that all parts in contact at any time were properly cleaned and polished.

In order to overcome the necessity of using the storage battery, or any other external source of energy other than the trolley current, an instrument was devised as shown in Fig. 5. In this instrument, in place of the Weston type ammeter, an instrument of the ratio galvanometer type was used, containing two pairs of coils, C_1 C_2, C_3 C_4, and a soft-iron armature of small section. These coils were connected up, as shown in the figure, between the trolley wire, T, and ground together with the resistance, R. One terminal of C_3 was connected to the spring, A, as shown, the cam being grounded. It will be seen from an inspection of this diagram that as long as the cam is still the pair of coils, C_3 C_4, are short-circuited, so that the magnetic field will lie straight across from C_1 to C_2, and the soft-iron armature will lie across this path, and a pointer attached to this will indicate the zero position. Now, as the cam, G, is rotated for a short period during each revolution, current will be allowed to flow through the coil, C_3 C_4, and will rise in proportion to the number of revolutions of the cam during any given period of time, and, following a well-known law, the resultant field due to C_3 C_4, and C_1 C_2, will take up an angular position whose tangent is equal to the

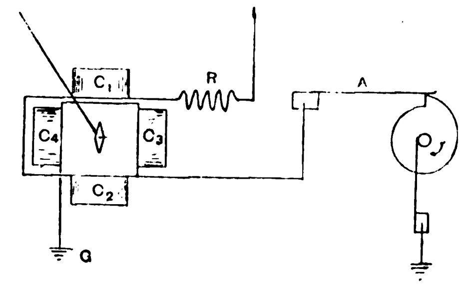

FIG. 5.

ratio of the strength of the two fields due to C_3 C_4 and C_1 C_2. Now, as the strength of the field C_1 C_2 (assuming constant voltage) has a steady value, this ratio will be in proportion to the strength of the field C_3 C_4—that is, to the speed of revolution of the cam. If the impressed voltage changes in any way, it changes equally in both sets of coils—that is to say, the ratio of the two currents, and, therefore, of the two magnetic fields, remains the same, so that the indicating instruments are absolutely independent of the impressed voltage, provided that it does not fall to such a low value that the soft-iron armature is not saturated. As this, however, happens at a very low value, the section of iron being very small, for all practical ranges this instrument will be independent of changes of voltage. It will be noted, however, that the cam, C (Fig. 4) is only capable of rotation in one direction.

Fig. 6 shows a form of cam which was devised, which is capable of rotating in either direction. In this case the single cam is replaced by a double cam, C, having similar upper and lower faces, and a diagonal channel connecting them. When the cam revolves in the direction

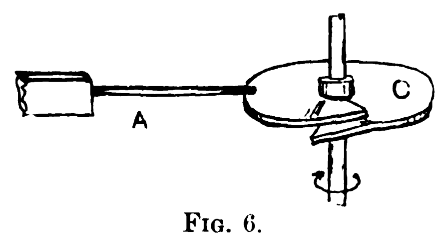

FIG. 6.

shown by the arrow, the spring, A, rises to the highest point on the upper surface and then falls to the lowest point on the upper surface, the operation being similar to that which takes place with the cam shown on Figs. 4 and 5. If, however, the direction of rotation is reversed, the spring, A, passes through the diagonal slot to the lower surface of the cam,

which is similar to the upper surface, but which operates in the opposite direction. Thus the operation of this cam is similar for either direction of rotation, provided the free position of the spring, A, lies in the mid position of the diagonal slot in the cam. It may be mentioned that this type of instrument should not really have been included in the scope of this article, as it promises to be fairly successful in operation. The fact, however, that the instruments which have been described, and which fall strictly within the heading of this article, suggested its conception, led to its being included. This only amongst the instruments which have been mentioned is covered by patents, although several of the other instruments have been patented at one time or another, and have since been abandoned.

In response to a request from some instrument makers to attempt to devise a speed indicator suitable for use with motor cycles, motor cars, etc., an instrument was devised after the following lines: The principle of the instrument depends on the measurement of the torque required to drive a fan at varying speeds. In the model first built the method of operation consisted in allowing the frame of a small clock gear which was driven by means of a pulley at the speed it was required to indicate, to be moved against the tension of a spring by means of the back torque of a fan connected to one of the gear wheels.

In another form of instrument the motion was communicated to the fan through a simple dynamometer, this being a form of the well-known differential gear. The center wheel of this gear was constrained to remain in a definite zero position by a spring, the angular change from this position being an indication of the power transmitted—that is to say, of the speed of the fan. An instrument of this sort is so dead beat that, provided a sufficiently elastic shaft is interposed, it can be driven by means of a ratchet motion actuated by an electromagnet, and yet give a fairly steady indication. Owing to want of time and opportunity, nothing further has been done with this instrument, and should our readers consider it worth while, they are at perfect liberty to follow it up.

The foregoing examples are a few of the most important of the experiments which have have been made by the author during the last five years, and we hope they will have proved of interest.

Dr. Haanel, superintendent of mines, heads the Canadian commission to investigate the electric smelting of ores in Europe.

ELECTRICAL STATION PRACTICE.

ARTICLE XX.

BY W. H. RADCLIFFE.

It has already been shown how a switchboard may be used to regulate, control and protect the electrical energy generated in the station, by means of rheostats, switches, circuit breakers, lightning arresters, etc. Mention has also been made of certain instruments mounted on the board for measuring the voltage and current, and as there are a number of details regarding the operation and maintenance of these, together with the operation and maintenance of meters in general that should be understood by the station attendant, this subject will now be taken up.

The meters previously represented in the switchboard diagrams given were voltmeters and ammeters of the direct and of the alternating current types. A direct current voltmeter consists essentially of a very high resistance connected in series with a coil of fine wire, the latter of which is free to turn between the poles of a permanent horseshoe magnet. Some voltmeters contain a switch or key for closing and opening the circuit through the meter, while others intended to be connected permanently in circuit are not thus equipped. Securely fastened to the top of the coil of fine wire is a pointer which projects above a graduated scale. The passage of a current through the fine wire coil produces lines of force which oppose those developed by the permanent magnet, and which therefore tend to cause a rotation of the fine wire coil about a vertical axis proportional to the strength of the current. The rotation of the coil is opposed at all times by the action of two flat spiral springs, one of which is fastened to the top and the other to the bottom of the coil. When no current is passing through the instrument the action of the spring pulls the pointer back to the zero position, which, in all commercial meters, is practically at the left-hand extremity of the scale. Inclosed within the fine wire coil is a cylindrical core of soft iron; this core does not revolve with the coil but serves to strengthen the magnetic field developed by current in the coil over what it would be were the space occupied by air instead of iron. Since the resistance of the meter is practically constant at all times, the current passing through it is directly proportional to the voltage applied across its terminals. Conversely, this voltage is proportional to the current. There is an old axiom that things proportional to the same thing are proportional to each other; therefore, since the voltage is proportional to the current, and the amount of rotation of the coil or the deflection of the pointer on the coil over the graduated scale is also proportional to the current, the deflection of the pointer is consequently proportional to the voltage. If, therefore, the scale over which the pointer rotates be properly graduated in volts, the position of the pointer over this scale will signify the number of volts to which the matter is subjected.

The graduations of the scale are made at the factory, by comparing the deflections of the pointer with voltages as measured on standard apparatus. The voltmeters in most common use have capacities of 5, 15, 75, 150, 300, 500 and 750 volts each, although in the measurement of very low resistances such as those of armatures, heavy cables, or bus bars, voltmeters having capacities as low as .02 volt are employed. The difference between the design of direct current voltmeters of different capacities lies simply in the high resistance joined in series with the fine wire coil. This resistance is usually about 100 ohms per volt capacity of the meter, and is composed of fine silk-covered copper wire wound non-inductively on a wooden spool. By a non-inductive winding is meant that the wire is doubled on itself before being wound on the spool, so that the magnetic field produced by one-half of the coil may be neutralized by the similar but reversed magnetic effect produced by the other half of the coil. In a voltmeter having a capacity of 150 volts, the resistance introduced would, according to the data just given, be 15,000 ohms, whereas in a voltmeter having a capacity of 300 volts, twice this resistance or 30,000 ohms would be used.

As the capacity of a voltmeter depends upon the value of the resistance in series with it, advantage is often taken of this fact in using with it an instrument known as a multiplier. The multiplier consists of a resistance suitably mounted, whose value in ohms is some multiple of the resistance of the voltmeter with which it is intended to be used. By this arrangement the resistance of the voltmeter circuit is increased a certain whole number of times, thereby decreasing in exact proportion the deflection of the pointer on the scale for a given number of volts. To compensate for the latter change, the deflections of the pointer must be multiplied by the amount of the resistance of the voltmeter circuit has been increased in order to obtain the exact voltage measured. To impress this statement more forcibly, the following example is given: Suppose a multiplier

having a resistance of 50,000 ohms be used in connection with a voltmeter having a capacity of 500 volts, and that a deflection of 400 be obtained on the scale. It is desired to know the voltage which will produce this deflection under the conditions mentioned. From the data previously given a voltmeter having a capacity of 500 volts will have a resistance of 50,000 ohms. This resistance added to the 50,000 ohms in the multiplier will give 100,000 ohms, and this is $100,000 \div 50,000 = 2$ times that normally contained in the meter, so that a deflection of 400 on the scale represents $2 \times 400 = 800$ volts. Although a given voltmeter together with a multiplier containing sufficient resistance might be used in this manner to measure any voltage employed, multipliers enabling pressures up to 40 times that of the scale readings have thus far been the only ones on the market.

The preceding principles laid down in this article apply to all voltmeters for direct current circuits. The details in the construction of these instruments, however, differ according to the service they are intended to perform. When designed for taking measurements in different places they are called portable voltmeters, and when designed for continual use in one place as on a switchboard, they are called station voltmeters. Portable voltmeters and station voltmeters will be taken up in the order named; the former are mounted on wooden bases with the working parts inclosed within metal dust-proof cases. Above the graduated scale on each instrument, an insertion of glass enables the deflections of the pointer to be observed, and to aid in obtaining the correct reading of the pointer there is placed on each portable voltmeter beneath the pointer and extending along the scale a mirror. The use of the mirror for the purpose mentioned consists in placing the eye in such a position that, when looking into the mirror, the reflection of the pointer will be entirely covered by the pointer itself; such being the case, the observer is in the proper position to secure the most accurate reading on the scale, since then he will be directly above the pointer. If the pointer when deflected does not readily come to a position of rest owing to friction in the moving parts, it may be aided in this respect by gently tapping the case of the instrument with the hand; this will often enable the obstruction, if not of a serious nature, to be overcome and an accurate reading obtained.

On many direct current voltmeters of the portable type there are two scales, the one for low voltage readings and the other for high voltage readings; on these scales the values of the graduations for low voltages are marked with red figures, while those for high voltages are marked with black figures. A voltmeter carrying two scales must also contain two resistances in place of one; a terminal from each of these coils must be connected with a separate binding post, but the remaining terminal of each resistance is joined to a wire which connects through the fine wire coil with the third binding post of the meter. The two first mentioned binding posts are usually mounted at the left-hand side of the metal case, and the last mentioned binding post and key at the right-hand side of the metal case. The resistance corresponding to the high reading scale is composed of copper wire having the same diameter as that constituting the resistance for the low reading scale, but as the capacity of the former scale is generally a whole number of times greater than that of the latter scale the resistances for the two must bear the same proportion. This means, since wire of the same size is used for both cases, that the lengths of resistance wire employed must be proportional. Thus, a voltmeter carrying one scale graduated to 5 volts and the other scale graduated to 500 volts, would require two resistances, one of which would be 100 times the length of the other.

In the connection of a two-scale voltmeter in circuit, the single binding post which, as previously stated, is usually on the right-hand side of the instrument, is always employed regardless of which scale is desired. If, then, the voltage be such that it may be measured on the low reading scale, the other binding post employed is that connected to the lower of the two resistances contained within; if, however, the pressure is higher than those recorded on the low reading scale, the binding post to use in addition to the one on the right-hand side of the instrument, is the binding post connected to the higher of the two resistances contained within. Inasmuch as the capacities of the scales are usually marked on or near the corresponding binding posts, there will generally be no difficulty in selecting which of the two left-hand binding posts to employ. In case these binding posts are not marked and only an approximate idea is possessed of the voltage to be measured, it is always advisable to connect to the high reading scale of the meter in order to determine if the measurement may not be made safely and more accurately on the low reading scale. In any case, some knowledge must be had of the voltage at hand, else the high reading portion of the instrument may be endangered. Too much care cannot be taken to observe these precautions whenever the voltmeter is used, for the burning out or charing of the insulation either in the fine wire coil or in the high resistance of the meter by an excessive current, is one of the most serious accidents that can befall the instrument.

If a voltmeter has been subjected to a voltage higher than that for which it was designed, yet not sufficiently high to injure the insulation, but high enough to cause the pointer to pass rapidly over the entire scale, damage has been done in another way. The pointer being forced against the side of the case in this manner, bends it more or less and so introduces an error in the readings that are afterward taken. The same damage will be done when the meter is connected in circuit so that the current does not pass through it in the proper direction, although in this case the pointer is not liable to be bent so much as when it is forced to the opposite side of the meter by an abnormal current, since then it has gained considerable momentum which causes a severer impact. The extent of the damage may be ascertained by noting how far away from the zero mark the pointer lies when no current is passing through the instrument. If this distance is more than two-tenths of a division, the metal case inclosing the working parts should be removed and the pointer straightened by the careful use of a pair of pinchers.

The location of a voltmeter has considerable effect on the results obtained from it. If it is placed near to conductors carrying large currents, the magnetic field developed thereby will produce a change in the magnetism of the instrument, and so introduce an error in the readings.

In wiring portable voltmeters in circuit, the connecting wires or cables must be firmly secured to the support on which the meter rests so as to reduce the possibility of their being pulled by accident, and so causing the meter to fall. A fall or a rough handling of the meter at once shows its effect on the readings, for as much harm is done as would result from a similar treatment of a watch. The hardened steel pivots used in all high grade voltmeters are ground and polished with extreme care so as to secure and maintain a high degree of sensitiveness. The jewels on which the moving parts revolve are of sapphire, and they too must necessarily be made with skill and carefulness; if, therefore, the jewels become cracked and the pivots dulled by

careless handling, the meter at once becomes useless as a measuring instrument.

When taking measurements, the deflections of the pointer should be read to tenths of a division; this can be done with considerable accuracy, especially after a little practice. For very accurate results, a temperature correction should be applied to the readings to compensate for the effect which the atmospheric temperature has upon the resistance of the meter when measurements are being taken. If, however, Weston's portable instruments be used, the temperature correction is negligible, being for resistance corresponding to the high scale less than one-quarter of 1 per cent. for a range of 35 degrees above or 35 degrees below 70 degrees Fahrenheit.

Station voltmeters of the direct-current type operate on the same principle as do portable voltmeters. They are, however, constructed larger, so as to be easily read at a distance, and the containing case is of iron. Iron is used principally because it shields the working parts of the instrument from external magnetic influences by collecting within itself the lines of force associated therewith. To render the deflections of the pointer easily discernible at a distance, the scale is composed of opal glass with black graduations; directly behind the scale an incandescent lamp is mounted, and this together with a pair of mirrors illuminates the background very evenly, permitting at the same time the graduations and figures to stand out most effectively.

In a station providing constant potential service, a great convenience is afforded by employing a voltmeter equipped with a normal index. This is a circular disk, usually of blackened aluminum, which projects over the scale just beneath the graduations; its position along the divisions may be varied by turning a knob mounted on the front of the case. By placing the disk so that it occupies a position directly beneath the point of normal voltage, the pointer when indicating this value will be immediately over it. Owing to a circular opening somewhat larger than the disk, cut out of the pointer at the part which travels on a level with the disk, there will be a narrow ring of white visible between the disk and circular opening when the pointer is in its proper position. A very small variation in the voltage developed can therefore be detected without difficulty at a considerable distance from the meter.

A station voltmeter being generally used to indicate the pressure of the generator wired to the switchboard, must of necessity be connected across the terminals of this machine, or across the leads running therefrom. Care must consequently be taken to guard against any short-circuiting of the voltmeter, which, of course, would mean a short-circuiting of the generator and as a result the probable burning out of its armature. The high resistance of the voltmeter prevents any such occurrence when it is connected in the proper way, but should one side of the circuit be grounded to the metal case or frame of the meter, a careless handling of the lead connected with the other side of the circuit would produce the result just mentioned. Station voltmeters are usually connected permanently in circuit; there is therefore a certain amount of heat developed in the wiring of the instrument which is proportional to the square of the current, the resistance of the voltmeter, and the time during which it is connected in circuit. This heating effect of the current increases the voltmeter resistance and consequently reduces the current below that which otherwise would pass through the meter; since the deflections of the pointer are in reality governed by the strength of the current, station voltmeters invariably indicate a voltage slightly lower than that which actually exists across the leads.

INTERURBAN ELECTRIC TRACTION SYSTEMS--A. C. VS. D. C.*

BY P. M. LINCOLN.

(*Concluded from page 25.*)

4. Attendance at Sub-stations Done Away With.—The direct current rotary being a piece of revolving machinery, of course requires manual attendance at the various sub-stations. Alternating current sub-stations consist of static transformers only, and therefore require attendance only for the purpose of operating the switches. Making the switching devices entirely automatic in their operation avoids the necessity of attendance for this purpose. A still further requirement is the use of distant controlled switches operated from a central point, say the main power house. Electrically operated switches have already been developed to be operated from a distance of several hundred feet, and no reason exists why this distance of operation cannot be extended to twenty or thirty miles by proper design.

5. Electrolysis.—Electrolysis of parallel conducting systems is generally recognized as one of the most serious dangers in connection with present direct current trolley systems, and the fact that an alternating current system avoids this danger entirely need only to be mentioned in order to be recognized as a marked advantage.

So much for the advantages which accrue to the alternating current system. Now, the question arises, what points must be sacrificed in order to obtain these advantages? The disadvantages which necessarily accompany the use of the alternating current traction systems are as follows:

1. Additional weight.
2. Difficulty of operating on existing lines.
3. Increased rail loss.
4. The fact that an active EMF. exists between field turns.
5. Possible interference with telephones.

Now, suppose the above points in detail be taken up:

1. Additional Weight.—An alternating current motor of a given capacity is necessarily somewhat heavier and more expensive than a direct current motor for the same capacity. This difference in the motor, however, does not constitute the total difference in weights of equipment. In order to make use of the advantages of high trolley voltage, the alternating current equipment should preferably be provided with a step-down transformer on the car. Also, in order to obtain the advantages of avoiding the rheostatic losses, some provision must be made for controlling the voltage on the car. The transformer, the voltage control apparatus and the greater weight of motors makes the alternating current equipment necessarily heavier than the direct current. Although this difference need not, and, in many cases, will not be as great (18 per cent.), still a difference in weight will always exist detrimental to the alternating current equipment. This greater weight of the alternating current equipment is one of the items on the debit side of the ledger.

2. Difficulty of Operating on Existing Lines.—Practically all interurban roads run in and through cities on existing tracks, and, therefore, must use the existing sources of direct current power. In order to meet this condition, the equipment for an alternating current interurban road must be so arranged as to operate outside the city and on direct current inside. Although this is entirely possible, it must necessarily prove to be a matter of considerable complication. It means, in the first place, the use of motors which can be operated from both direct and alternating current. This is entirely possible with the series alterna-

*Abstract of paper read before the Electrical Section of the Canadian Society of Civil Engineers, Nov. 19, 1903.

ting current motor. It means, in the second place, that another system of control must be added to the car. This objection might in part be avoided by using rheostatic control for both the alternating current and direct current conditions, but the objection obtains that this method will deprive the alternating current system of its advantage of saving rheostatic losses.

3. Increased Rail Loss.—Experiments have shown that with alternating current from 2,000 to 3,000 alternations, the actual loss which takes place with a given current through the iron rails is from three to five times that which the same direct current would give. The ratios of loss hold for the higher frequencies. At first thought this seems to be an important objection to the a. c. system. But when it is considered that in order to utilize the main benefit of the alternating current, a higher trolley voltage is used, and therefore, smaller currents in the return conductor, the element of rail loss in an alternating current proposition may be made even a smaller proportion of the total than in the direct current in spite of this apparently large handicap. The rail loss with direct current is usually a small proportion of the total and this with alternating current, at the trolley voltages which are usually considered, viz., 2,000 to 5,000, becomes a much smaller proportion.

4. Active EMF. Between Field Turns.—The space that can be assigned to the motor for operating a car is necessarily limited. It is this limitation of space, in fact, which often forces the use of a four-motor equipment instead of a two, the available space not being large enough to allow the installation of motors, two of which are sufficient for the work. When we consider the a. c. motor, the question of space available becomes still more exacting, first, because the a. c. motor is necessarily heavier, and therefore occupies more space than an equivalent d. c. motor; and, second, because the active EMF. that exists between the field turns in the a. c. motor, and which, other things being equal, again requires additional space for insulation. In the matter of EMF. between field turns, the a.c. and d.c. motor are quite different. The EMF. between the field turns of a d. c. motor is due simply to ohmic resistance and a short circuit between turns simply throws out of action the turns so short-circuited, and, if not too severe, does not interfere seriously with the motor's operation. Between field turns of the a. c. motor, on the other hand, there is an active EMF. similar to that between turns of a transformer winding. A short circuit between field turns in an a. c. motor, therefore, means a destructive short circuit and an immediate interruption of service from that motor.

5. Interference with Telephones.—It is a question whether alternating current in the rails will interfere with telephones and similar instruments more than the direct current which they have to contend with at present. In any event, the amount of current in the rails can be reduced by the use of higher voltages so that this source of interference can be made less than it is with the present direct current system. Further, means have been proposed whereby the current can be confined entirely to separate conductors provided for the purpose, and not allowed to wander at will through any return circuit that may exist, as is the case with the direct current system. This can be done, of course, only at the expense of erecting a separate system for the return currents and a system of series transformers whereby these currents can be confined to this return system. The alternating current system, therefore, possesses the advantage of being able to use the rails for contact and still not allow the alternating currents to escape at will through the earth. As a matter of fact, interference with other circuits by the alternating current system is expected to be less than with the present direct current system.

Society of Chemical Industry.

The next meeting of the New York Section will be held at the Chemists' Club, 108 West 55th street, Friday evening, January 22, at 8:15 o'clock. Papers will be read by J. Merritt Matthews, Martin L. Griffin and Edward Durant.

PERSONAL MENTION.

Mr. Irving H. Reynolds, formerly with the Allis-Chalmers Company, and for many years identified with the design and construction of that company's engines, has accepted a position with the William Tod Company of Youngstown, O., as consulting engineer.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 12, 1904.

Electric Railways and Appliances.

749,160. Electrically-Operated Railway-Switch. Claude W. Breedlove and Rudolph R. Grant, Berkley, Va. Filed March 25, 1903.

749,301. Trolley-Stand. Washington H. Kilbourn, Greenfield, Mass., assignor to the Stanley Electric Manufacturing Company, Filed Aug. 14, 1902.

749,401. Electric Railway. Leon W. Pullen, Philadelphia, Pa., assignor to the Wireless Railway Company, same place. Filed April 18, 1903.

749,509. Trolley. Willis D. Williams, Kirkland, Ariz. Filed Aug. 19, 1903.

749,597. Electric-Railway Switch. Johann G. Weniger, New York City. Filed June 9, 1903.

749,601. Trolley-Harp Device. Frederick H. Allen, Dunkirk, N. Y. Filed Nov. 2, 1903.

Electric Lights and Appliances

749,268. Electric-Arc Lamp. George R. Davison, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed May 8, 1903.

749,500. Miner's Electric Lamp. Henry G. Prested, Camden Town, Eng. Filed Feb. 7, 1903.

Electrical Machinery and Apparatus.

749,255. Electric Interlocking Switch and Signal System. Gustave Bleynie and Theophile Ducousso, Paris, France. Filed March 6, 1902.

749,271-749,272. Electric-Motor Control and Motor Control. Samuel T. Dodd, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company, Filed June 4-13, 1903.

749,324. Electric Sparking Ignition Apparatus for Gas Rock Drills, John V. Rice, Jr., Edgewater Park, N. J., assignor to the John V. Rice, Junior Company, same place. Filed June 8, 1895. Renewed July 16, 1898.

749,416. Safety-Appliance System for Electrically-Actuated Elevators. Harry G. Wright, Providence R. I., assignor to William C. Woodward, same place. Filed May 9, 1903.

749,439. Electrical Controlling Apparatus. John D. Ihlder, Yonkers, N.Y., assignor to the Otis Elevator Company, East Orange, N. J. Filed March 22, 1902.

Telephones and Telephone Apparatus.

749,225. Telephone System. Hope Redmon, Rufus L. Hall and Robert H. Conway, Cynthiana, Ky. Filed Nov. 10, 1902.

749,306. Telephone System. Albion D. T. Libby, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Dec. 3, 1902.

749,308. Telephone-Exchange. Frank A. Lundquist and John K. Norstrom, Chicago, Ill., assignors to M. E. Richardson, trustee, Sterling, Kan. Filed Nov. 19, 1900.

749,388. Locking Device for Telephone Apparatus. Sherwood J. Larned and James S. Ford, Chicago, Ill., assignors to the American Telephone & Telegraph Company. Filed Oct. 9, 1903.

749,399. Alternating-Current Relay. Greenleaf W. Pickard, Amesbury, Mass., assignor to the American Telephone & Telegraph Company, Filed Aug. 21 1903.

749,448. Telephone-Transmitter. Philip G. Randall, Boston, Mass. Filed Feb. 9, 1903.

749,481. Telephonic Repeater. Merritt Gally, Brooklyn, N. Y. Filed April 18, 1903.

Miscellaneous.

749,178-749,434. Wireless Signaling Apparatus. Lee De Forest, New York City. Filed March 5, 1903, June 4, 1903.

749,185. Electrode. Rudolf Hager, Halensee, near Berlin, Germany. Filed Jan. 31, 1901.

749,191. Electric Signaling Apparatus. Felix B. Herzog, New York City. Filed May 17, 1886.

749,199. Skeleton Frame for Tanks or Cells of Electric Batteries. Daniel F. Jones, Providence, R. I. Filed Oct. 17, 1903.

749,335. Insulator. Louis Steinberger, Brooklyn, N. Y. Filed Sept. 18, 1902.

749,336. Insulated Support for Wires. Louis Steinberger, New York City. Filed Nov. 12, 1902.

749,365. Electric Bell. Harry E. Dey, New York City. Filed Aug. 15, 1901.

749,371. Wireless Telegraph Receiver. Lee De Forest, New York City. Filed June 4, 1903.

749,372. Art of Wireless Telegraphy. Lee De Forest, New York City. Filed June 4, 1903.

749,387. Automatic Non-Interfering Repeater for Fire Alarm Circuits. William H. Kirnan, Bayonne, N. J., assignor to the Gamewell Fire Alarm Telegraph Company. Filed Oct. 4, 1902.

749,391-749,392. Bond and Elbow for Conduits for Electric Wires. George A. Lutz, New York City, assignor, by mesne assignments, of one-half to Frank K. Boland, same place. Filed May 7, 1901. Renewed June 5, 1903.

749,426. Lightning-Arrester. William E. Cone, Memphis, Mo. Filed May 28, 1903.

749,435. Generating Set for Wireless Telegraph. Lee De Forest, New York City. Filed June 17, 1903.

749,436. Wireless-Telegraph Range-Finder. Lee De Forest, New York City. Filed June 17, 1903.

749,460-749,461, Electric Furnace. Le Roy W. Stevens and Bernard Timmerman, Chicago, Ill., assignors to the Advance Furnace Company of America. Filed Aug. 8, 1902, Oct. 29. 1902. Renewed June 17, 1903.

749,495. Electric Striking Clock. William Olsen, Jersey City, N. J. Filed Dec. 31, 1902.

749,584. Wireless Signaling System. Harry Shoemaker, Philadelphia. Pa., assignor, by direct and mesne assignments, to the International Wireless Telegraph Company and Marie V. Gehring, Philadelphia, Pa. Filed Oct. 3, 1902.

749,628. Electric Heater. George J. Peacock, Pittsburg, Pa., assignor of one-fourth to Charles Bonini, same place. Filed April 19, 1902.

749,633. Electrical Hose Signaling Apparatus. William G. Seeley, Brookline, Mass. Filed May 25, 1903.

THE TELEPHONE WORLD.

Independent Companies Resist Postmaster General's Order.

According to a dispatch from Cleveland, O., the order of Postmaster General Payne, which bars from the Post Office of the United States all Independent telephones, has raised a row. The order prescribes that only the instruments of the companies that have long-distance connections with Washington shall be used. This means that the Bell Company shall have a monopoly of the business.

In the Middle and Western States the Independent companies have a very extensive service and their charge of discrimination is being taken up by Congressmen. Cleveland, as the headquarters of many of the largest of the companies, has started the fight against the order, and it is aided by the National Association of Independent Telephone Companies and the State Telephone Association. A personal appeal has been made to President Roosevelt, who has promised to make an investigation.

Senator Hanna has been appealed to by capitalists interested in the Independent companies, many of whom are his warmest friends. Congressmen, too, have been interested, and the question is certain to be entangled with politics. While New York, Boston, Baltimore and Washington are the only big cities in the East without an Independent company, Cincinnati is the only city between the Alleghenys and the Rockies that has not a large list of Independent line subscribers.

The president of the Cuyahoga Company, Independent, has declined to remove his 'phones, saying that he will make a fight and trust to the courts for his money.

At a meeting of the Southern Iowa & Northern Missouri Telephone Association, held recently in Kirksville, Mo., it was decided to form a company with a capital stock of $100,000, for which bonds will be floated for the purpose of constructing a long-distance line from Moberly through Macon, Kirksville, Lancaster, Southern Iowa, Des Moines, Downing, Memphis, Kahoka and Keokuk. A committee, of which J. M. Kennedy was made chairman, was appointed to organize a company.

The American Car Telephone Company, capitalized at $2,500,000, was lately added to the list of Grand Rapids, Mich., big corporations. Although incorporated under the laws of Arizona, its general office will be in Grand Rapids. The officers are: Theodore Morgan, of Muskegon, president and general manager; F. W. Lyle, Dowagiac, vice-president; E. L. Siver, Grand Rapids, secretary and assistant general manager.

George Finch, of Escanaba, Mich., owner of the Finch Independent telephone system there, will extend his toll lines from Delta County to Menominee and Cedar River, in Menominee County. The work will commence early in the spring. Mr. Finch also intends to apply for a franchise to build a telephone system in Menominee in opposition to the Bell.

W. A. Booth, P. B. Davis and G. M. Cornett have formed a company with a capital of $10,000 to build 60 miles of telephone lines between Prineville, Bend and Sisters, Ore.

Representatives of Independent Companies Confer.

Representatives of 13 Independent telephone companies in Central and Western Illinois met recently in the offices of C. F. Tonn, general manager of the Illinois Telephone Company in Jacksonville, Ill., for the purpose of organizing an Independent Telephone Association and arranging matters so that it will be clearly understood what part of the gross charge each company is to receive for the transmission of a long distance message, or of messages other than local.

It is expected during the present year to establish copper metallic circuits between Hannibal, Springfield, Alton, Louisiana, Jacksonville and other cities of importance in the district embraced by the following counties, which were represented in the meeting: Calhoun, Jersey, Macoupin, Greene, Scott, Morgan, Cass, Sangamon, Pike, Adams, Brown, Hancock, Hannibal and several counties in Missouri.

When copper wires have been stretched between the leading cities in these counties a long distance circuit will have been established, and will be of inestimable value to the various Independent companies. It is also expected that the wire through to Chicago will be completed during the coming summer, when communication may be had direct with that city. Preliminary steps were taken at the meeting toward fixing the amount of toll due each company when a long distance message is transmitted through several of them.

The following gentlemen were present at the meeting: C. F. Tonn, general manager of the Illinois Telephone Company; J. L. Jennings, of Fayette; W. H. Ramsey, of Auburn; John G. Pratt, of Virginia; E. D. Boynton, of Pleasant Plains; W. G. Tucker, of Virden; W. J. Finch, Jr., of Chesterfield; A. T. Vanninan, of Girard; A. F. Loehr, of Carlinville; Ed. D. Glandon, of Pittsfield; H. G. Conger, of Hannibal; F. W. Kelley, of Springfield, and W. B. Rogers of Waverly.

Nine of the leading citizens of Estherville, Ia., have formed an Independent telephone company, and have petitioned the city council for a permit to build, operate and maintain an Independent system in Estherville. The new company expects to extend its lines to the rural districts and to connect with other lines on all sides of Estherville. It is said to have plenty of capital behind it.

The annual meeting of the Rome, N. Y., Home Telephone Company was lately held. Fred M. Shelley was re-elected president; John S. Wardwell, vice-president; and D. Odell secretary, treasurer and manager of the company. The company now has 1,004 'phones in service in that city.

According to Dover, Del., dispatches, the Diamond State Telephone Company has bought control of its last competitor on the peninsula, the Peninsular Telephone Company, which has a system of 125 miles, extending to Virginia.

The Chicago Telephone Company now has 101,200 telephones in service having added 1,600 in December. The gain for 1903 was about 22,100 instruments.

Growth of a Western Company.

Two years ago a few of the citizens of Benedict, Neb., organized the Benedict Telephone Company with $10,000 capital stock, with the idea of putting in some 'phones in the village and two or three lines in the country for the convenience of business interests. In one year they reorganized and became the York County Telephone Company, with authorized stock of a half a million dollars. To-day they have toll connections with over 30 towns and over 1,000 'phones in York County. The board of directors of the company are some of the solid men of the county, and the company has succeeded beyond their most sanguine expectations. Two years ago when the switchboard was purchased for Benedict it was supposed it would not be filled up for years, but to-day it is full and people are clamoring for 'phones that cannot be supplied until a new switchboard is secured.

The San Diego, Cal., common council lately sold to Arthur Wright, of Los Angeles, a telephone franchise for San Diego for $300. It is understood the purchaser represents the Home Telephone Company. He will put in a guarantee bond to expend at least $120,000 in the construction of a plant. The franchise will be formally awarded in 30 days. There was no opposing bid, although representatives of the Sunset Company were present.

A certificate filed with the State Department at Albany, N. Y., sets forth that the Baiting Hollow & Roanoke Telephone Company of the town of Riverhead has increased the amount of its capital stock from $5,000 to $20,000. The company's directors include A. B. Young, Charles H. Warner, H. R. Talmage, John C. Young, F. O. Reeve, E. E. Mosier and W. R. Fanning.

W. E. L. Gaine, general manager of the National Telephone Company of Great Britain, accompanied by Frank Gill, engineer in chief of the company, are making a tour of this country and Canada visiting telephone and electrical plants. They have a great telephone system in their own country, but Mr. Gaine said they never come to the United States but they gain ideas.

At a recent meeting of the Taylorsville & Bethlehem Telephone Company, at Elk Creek, Ky., the following officers were elected: President, William V. Wiggington; secretary and treasurer, William McMakin; general manager, Dr. J. L. Long, and Arthur Van Arsdale, lineman.

The Athens, Tenn., Telephone Company has changed hands and is now owned and managed by Eugene Horton, who is preparing to overhaul the plant and put it in first-class condition.

The Monrovia, Cal., Telephone & Telegraph Company has filed a certificate of bonded indebtedness of $25,000.

G. Y. Stamp, of Melrose, Ky., has bought the telephone exchange at Stithton, Ky., formerly owned by H. W. Bryant.

A telephone system connecting Lorane with
projected.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Attica, O.—This city will vote to issue $6,250 of bonds for electric light purposes.

Clinton, Ia.—The Dewitt Electric Light & Power Company has voted to purchase a new and larger dynamo and perhaps a new engine, as the present two are too small.

Clinton, S. C.—It is stated that an electric plant is to be erected at Musgrove Mill on Enoree River for Thornwell Orphanage. Rev. W. P. Jacobs, president.

Colfax, Wash.—Nicholas Codd, one of the proprietors of the Colfax electric light plant, and James A. Ralph have bought the electric light plant at Dayton. Mr. Ralph will have charge of same.

Creston, Ia.—M. E. Springer, of Des Moines, may install an electric light and gas plant here.

Eau Claire, Wis.—The city council has appointed a committee to investigate the desirability of city ownership of the electric light plant, and requested the Commercial Association to appoint a committee.

Elizabethtown, Pa.—The Elizabethtown Electric Light Company will enlarge its building and add sufficient machinery to more than double the capacity of the present plant.

Fairmont, Neb.—Electric lights are again being discussed here.

Hailey, Idaho.—Harry J. Allen proposes to construct an electric plant to cost about $75,000, to supply power and light to this town, Ketchum and B ll vue.

Hamilton, O.—The Hamilton Heating & Power Company has asked for a franchise for a lighting and heating plant here.

Langdon, N. D.—A new dynamo is to be installed in the electric light plant here.

Lexington, Ky.—A franchise is to be asked here for a new electric lighting plant. W. H. McCorkle is interested.

Matehuala, Mex.—James Kilton has obtained a contract for supplying this city in the State of San Luis Potosi, with electric light and power and to establish a waterworks system. Work has been started. Four electric generating stations will be erected.

Middletown, Ill.—An electric light plant is to be erected. Mr. Allison is interested.

Negaunee, Mich.—The municipal electric light plant is to be improved at a cost of $15,000.

Newton Falls, O.—A proposition to establish an electric lighting plant has been made to the council, but the citizens want waterworks and sewers in addition to street light.

Norwich, N. Y.—The Norwich Gas & Electric Company is negotiating for a contract to light this village.

Oneida, N. Y.—There is a movement under way to start an electric light plant here.

Opelika, Ala.—The Alabama Electric Light & Power Company has been incorporated with a capital of $50,000 by C. S. Abercrombie, H. C. Davidson, of Montgomery, and others.

Pelican Rapids, Minn.—The village council has voted to issue $5,000 more in electric light bonds, making $15,000 in all.

Pitcairn, Pa.—The electric light plant here was lately damaged by fire.

Pittsfield, Ill.—The Pittsfield electric light and power plant was sold to Kendal & Whiting of Geneva Lake, Wis., for the sum of $20,000.

Salt Lake City, Utah.—General Manager Campbell, of the Utah Light & Railway Company states that the company will make a number of improvements to the plant. The power plant is to be increased considerably.

Sandersville, Ga.—Sealed proposals will be received by the water and light commission of this city, of which W. A. McCarty is chairman, until January 27, for constructing a complete system of waterworks and an electric light plant. The electric light plant is to consist of two electric generators, 50 and 75 kw. capacity; two high-speed engines, 75 and 110 hp; switchboards and station instruments; 40 arc lights, 2,000 cp.; complete arc and incandescent circuits, transformers, etc.

South McAlester, I. T.—This city has outgrown its electric light plant and power house.

Taylorsville, O.—At a recent meeting of the town council a proposition was submitted for lighting of the streets and public buildings of the town with electric lights. The proposition was submitted by Messrs. William H. Frazier, of this place, and ex-Senator C. U. Shryock, of Zanesville.

Waddington, N. Y.—This town, at a special election, has voted to sell its municipal electric light plant and water power and rights to a Canadian company for $3,750, the amount which remains unpaid on the plant. The municipal operation of the concern has not proved satisfactory.

Wilkes-Barre, Pa.—The Co-operative Electric Light Company is being organized with Frank Slattery, attorney, as president.

STREET RAILWAYS.

Brazil, Ind.—H. D. Falls and O. E. Adams are the promoters of an interurban electric line between this city and Diamond.

Brooklyn, N. Y.—The Brooklyn Rapid Transit Company expects to abandon the locomotive service entirely on April 1.

Cooperstown, N. Y.—The long and expensive litigation which since last May has prevented the completion of the trolley line to Mohawk has come to an end and Superintendent Jennings is given 18 months to complete the road, and $250,000 to do it with. Work will be resumed in the spring.

Dubuque, Ia.—The Interstate Construction Company, which will build an electric line from here to Platteville., Wis., has been incorporated with a capital stock of $750,000. Peter Kiene of this city is president.

Durand, Mich.—The common council here has been asked to grant J. D. Leland, cashier of the First National Bank, and Charles Irwin, of Philadelphia, a franchise to operate an electric railway in this city.

Elkhart, Wis.—A new franchise was granted the Sheboygan, Elkhart Lake Railway & Electric Company to lay tracks in this village.

Granite, Ill.—The St. Louis, Granite City & Alton Traction Company has been incorporated with a capital stock of $150,000, and W. H. Warnock, F. E. Allen, D. Francis and others as the directors.

Harrisburg, Pa.—The Valley Traction Company and the Harrisburg & Mechanicsburg Electric Company have been merged. The lines cover all the lower part of Cumberland County, Pa., and extend into this city. M. C. Kennedy, of Chambersburg, is president. It is understood that leases of several other lines in Cumberland and York Counties will be secured.

Lancaster, Pa.—A movement is on foot to build a trolley line to connect with the Strasburg line. C. R. Kerr has been chosen president of the new company.

Napoleon, O.—There is a project on foot, which has every prospect of success, to build an electric railway line from Detroit to this place. The company will be known as the Cincinnati, Toledo & Detroit Short Line, and will be capitalized at $500,000.

Nashville, Tenn.—Dr. J. R. Shepard and his associates are the promoters of an electric road from here to Lewisburg.

New York City.—The New York, Westchester & Boston Railway Company has perfected plans for a modern third rail electric road from this city to Port Chester. The route is almost an exact duplicate of that laid out by the New York & Port Chester Railroad. William L. Bull, former president of the Stock Exchange, is president. Dick & Robinson, of No. 30 Broad street, are members of the financing syndicate There will be an issue of $15,000,000 first mortgage 5 per cent. gold bonds.

Rock Falls, Ill.—The Dixon, Rock Falls & Southwestern Electric Railway Company is to locate its power plant and car barns here.

Toronto, Ont.—J. H. Coburn, of Walkerville, will apply to the Ontario Legislature for a charter for an electric railway from Windsor to Walkerville.

Wilkes-Barre, Pa.—The indications are that in a short time there will be third-rail electric systems in connection with several of the railroads in this vicinity. It is now known that the Delaware & Hudson Railroad will equip its road between here and Carbondale with a third-rail system for passengers.

POWER PLANTS.

Bloomington, Ind.—The Indiana State University will erect a power plant, 50 x 100 feet, of brick and stone construction, which will cost $20,000.

Granville, N. Y.—The Granville Electric Light & Gas Company has acquired water rights at the outlet of Lake St. Catherine near here. The purpose of the company in acquiring these water rights is to dam the lake and use the fall to generate electricity for lighting and power. A dam will be built at the outlet, the source of Mettowee Lake, and a storage reservoir established. By means of this dam and one already established where the Mettowee River flows through Granville, it is expected 200 hp. can be developed in dry weather. The officers of the company are: President, F. D. Pember, Granville; vice-president, Brodie G. Higley, Sandy Hill; secretary and treasurer, E. R. Norton, Granville.

Seattle, Wash.—The Everett Improvement Company will harness May Creek near Wallace for electric power. George Montardon is the engineer in charge. Work will soon commence on dams, etc., necessary to develop 10,000 hp.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅝@12¾c; Lake, 12¾@12⅞c.; casting, 12½@12⅝.

The annual stockholders' meeting of the Chicago City Railway Company will be held in Chicago, February 16.

The Minneapolis General Electric Company has declared a dividend of $3 per share on its preferred stock, payable February 1.

The Chicago & Milwaukee Electric Railroad closed the year with a gross gain of 53 per cent. and a net gain of 75 per cent.

The Edison Electric Illuminating Company, of Boston, has declared a 2½ per cent. quarterly dividend, payable February 1.

The Chicago Edison Company has declared a regular quarterly dividend of 2 per cent, payable February 1, to holders of record January 23.

Another suit has been brought against the American Telephone & Telegraph Company on a patent involving the long distance transmission.

An Electric Storage Battery director says the 1903 year's earnings ran about $4,000,000, the largest business the company ever did, and that 10 per cent. can be shown earned on the stock.

The Butte (Mont.) Electric & Power Company declared a regular quarterly dividend of 1¼ per cent on its preferred stock, payable February 1. Books close January 28 and re-open February 2.

Judge Grosscup made no announcement before convening court in Chicago on Monday, concerning when he would decide upon the North Chicago dividend rate. While it is popular belief that the dividend will be 1¼ per cent., there is doubt in the minds of some as to whether or not such can be paid.

Interborough Rapid Transit, of New York, which showed considerable activity at the close of last week, netting 8¼ points gain for the week, showed increased strength Monday. About 1,000 shares were traded in, the price reaching 103½, and it closed at 103, a net advance of 2½.

The Chicago City Railway franchise extension will come before the city council January 25. No change looking toward municipal ownership will be allowed to enter the measure. The only question is that of compensation to the city. Ten per cent. of the gross receipts seems to be the most favored amount.

The Illinois Telephone and Telegraph Company filed for record with the County Recorder in Chicago on Monday a bill of sale for all its property, including tunnels, tracks, telephone cables and automatic switchboard appliances and telephone system. The bill of sale runs to the Illinois Tunnel Company, an Illinois corporation recently chartered, with an authorized capital of $30,000,000 and the power to issue as much more in bonds. Accompanying the bill of sale there was also filed for record a trust deed for $30,000,000 on the assets of the new corporation to secure a bond issue.

The New Jersey & Hudson River Railway & Ferry Company, which operates the ferry between the foot of West 130th street, New York, and Edgewater, N. J., and the electric railway from the New Jersey ferry terminal though Fort Lee, Englewood and Hackensack to Paterson, has just secured control of the Hudson River Traction Company, which owns the railway running south from Hackensack to the outskirts of Newark. An arrangement has also just been concluded between this company and the Public Service Corporation, whereby the Hudson River Traction Company's cars will be run through, without change, to Newark and Passaic

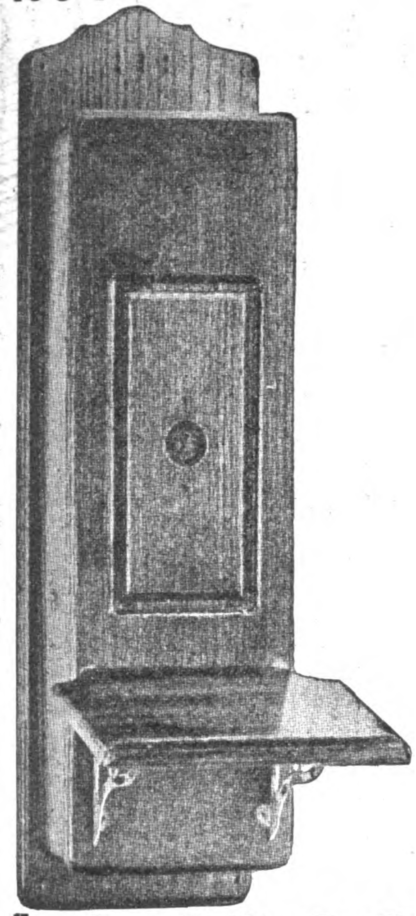
We Make All Kinds of Boxes and Cabinets for the Electrical Trade



WE CAN ACCURATELY DRILL THEM FOR YOU SO THAT THEY ARE ALL READY FOR THE ASSEMBLING OF THE METAL PARTS. SEND US YOUR SPECIFICATIONS AND LET US QUOTE YOU.

Our Specialty is

High Grade Finish and Accurate Work.

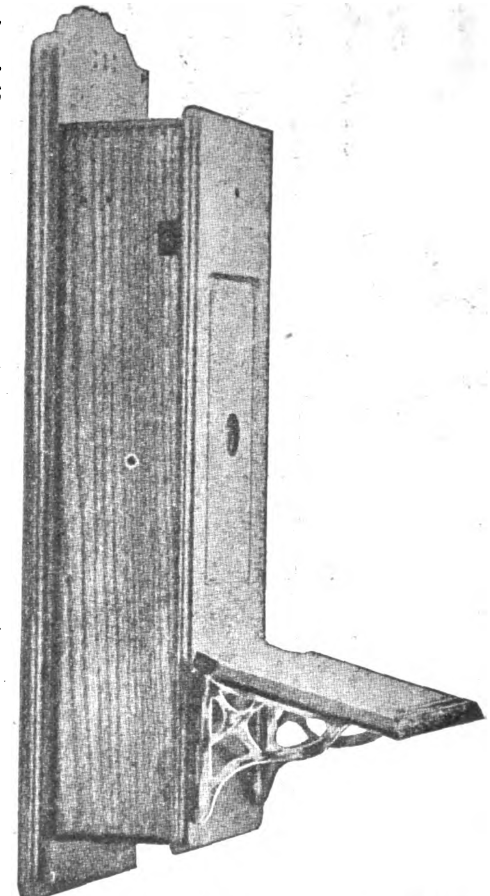
These two cuts show our new Compact Cabinet with nickel-plated brackets supporting the paper shelf. The paper shelf and nickel-plated brackets are removed in shipping. Doing this saves room, avoids scratching, and facilitates shipping.

The nickle-plated brackets make a handsome contrast with the highly finished quarter-sawed oak front and paper shelf.

We Can Furnish These Cabinets All Drilled Ready for the Working Parts.

In addition to the above cabinet, we make all of the standard styles including

CENTRAL ENERGY, MAGNETO BOXES, CABINETS FOR RESIDENCE PHONES, ETC.



LA CROSSE CABINET CO., LA CROSSE, WIS.

GONZALOS OIL CO.,

170 West Broadway, New York.

REFINERS OF BUENA VENTURA BRANDS OF

Lubricating Oils and Compounds
Floor Oils and Greases.

TELEPHONE 4479 J FRANKLIN.

"ELECTRICITY,"

IS ONLY $1 A YEAR.

ELECTRICITY.

VOL. XXVI. NEW YORK, JANUARY 27, 1904. NO. 4.

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

EDITORIAL NOTES.

The Northwestern Electrical Association Convention.

The convention held last week in Milwaukee by the Northwestern Electrical Association was replete with good things. A number of valuable papers on up-to-date subjects were read and thoroughly discussed, and an interesting and instructive lecture on radium was delivered by Prof. R. A. Milliken.

The president's address with the proceedings will be found on another page of this issue. The convention wisely decided to hold its midsummer meeting in St. Louis in conjunction with other electrical associations who will assemble at the Exposition in September.

We will print the most interesting papers read at the Milwaukee meeting in early issues of ELECTRICITY.

High-Speed Trials in this Country.

The high speed railway trials which have been going on for some time at Zossen, in Germany, and in which a speed of about 130 miles an hour has been obtained, are, according to the latest reports, likely to be duplicated in this country.

The New York Central Railroad assisted by one of the leading electrical manufacturing companies will, in all probability, undertake in the near future a series of speed tests with electric locomotives.

At a recent conference in Schenectady, N. Y., of the railroad officials and of several engineers representing the manufacturing concern the question of the tests was gone into quite thoroughly.

The party inspected the apparatus being constructed for the electrical equipment of the New York City terminal of the railroad, and also the stretch of the Central tracks near Schenectady where the proposed speed tests are to be held. The railroad company has just completed a detour of the city for the use of its freight trains. This will leave idle the present freight tracks, a well built stretch about eleven miles in length, and it is planned to use these two tracks for the tests of new electric locomotives.

One of the engineers at the conference is reported as saying:

"It is believed that the new apparatus being built for the New York Central Railroad will be able to attain a speed of more than 100 miles an hour. These locomotives will at least beat the record of 65 miles an hour made on the private tracks of the General Electric Company last summer. The Electric Company officials are confident the records made at Zossen will be equalled, if not beaten, by apparatus constructed in this country."

If these high speed trials come off, the results will be watched with interest by the electrical and railroad world.

* * *

Another Railroad Safety Device.

We have frequently referred in these columns to various devices that have been brought out to prevent railway accidents, more especially on roads making use of the third-rail. A resident of Rutland, Vt., has recently patented a block signaling device which he believes will make impossible such disasters as occurred in the Park avenue tunnel in this city. In fact, the inventor declares that his system will practically eliminate collisions of any kind on any road. From this it will be seen that the gentleman is nothing if not optimistic.

The invention provides for an electric block system by which it is impossible for more than one train to be upon a single

block at the same time. This is accomplished by setting track signals and flashing danger lights in the face of the locomotive engineer. Unlike several such schemes, the current is not obtained from a storage battery. Instead the power comes from track circuits placed between the rails.

When an engine enters a block a shoe underneath strikes the contact rail in which the power lies. This completes two circuits and instantly sets electric light signals wherever placed. The current passes to lamps in the cab, flashing a red light in the face of the driver and warning him of danger. Each block is controlled by the one preceding, so it is impossible for one train that is following another to come closer than the distance of one block without the engineer receiving two warning signals. One is a semaphore at the side of the track and the other is in the cab in front of his face. The warnings are the same whether the train is moving backward or forward.

An extra precaution is a pilot lamp which indicates whether the system is in perfect operation. If this lamp burns then the current is on; if it goes out it shows that there is something wrong with the current.

A daily paper, commenting on the system, states that one of the great advantages is that the engine driver has no levers to work, no mechanism to operate, and further does not have to depend upon man for his warnings. He simply has to keep his eyes open.

But here would seem to be the weak point. An engine driver does not always *keep his eyes open.* Another invention which automatically applies the brakes in case of danger, whether the engineer is awake or asleep would seem to be the better.

* * *

Electric Towing Device for Champlain Canal.

It looks very much as though the Champlain Canal might in the near future be equipped with an electric towing device. The New York State Superintendent of Public Works in his annual report just issued speaks as though in many respects he favors the scheme. A company that experimented for some time at Schenectady, N. Y., last fall with an electric towing device, has offered to equip the entire canal with its patent system. The work is to be done at the expense of the company, and it demands in return the exclusive right to maintain its system on the canals.

The Superintendent of Public Works in his report is cautious in giving his official approval to the plans of the company. He says he cannot indorse its offer to extend its proposed monopoly to the entire canal system, "because of the construction that might be placed upon such act by the public," and he adds that he has been "nearly convinced" by "careful consideration" that it should be let in on the Champlain Canal.

There is no doubt but what electric towing should be adopted on the canals, but it is questionable whether any one company controlling a certain device should have a monopoly.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Berlin, Germany, street railroads in 1903 carried over 300,000,000 persons, exceeding all previous records.

The General Electric Company is expected shortly to make an announcement of a development in alternating current work which will be of a revolutionary character in the electrification of steam railways.

What is claimed to be the richest radium-bearing earth in the world has been discovered in the Llano gold and coal fields, 115 miles north of Austin, Tex.

The Weather Bureau of the United States Department of Agriculture has established on Governor's Island a storm warning display station equipped with high power electric lights. Hereafter all storm warnings, flags by day and lights by night, will be displayed at that point.

In a recent article on steam ferries in this country, *Engineering*, of London, says: "On the Hudson River thousands of *railway carriages* are conveyed on large lighters pulled by ordinary tugboats. The italics are ours. We would call them freight cars.

The 183d meeting of the American Institute of Electrical Engineers will be held at the Chemists' Club, 108 West 55th street, on Friday evening, January 29, at 8:15 o'clock. The following papers will be presented at this meeting: "The Alternating Current Railway Motor," by Charles P. Steinmetz. "Speed Torque Characteristics of the Single-Phase Repulsion Motor," by Walter I. Slichter. These two papers relate to the latest and most interesting advance in electrical engineering as applied to traction purposes. Prof. Steinmetz's paper deals with the subject from a simple mathematical point of view, and Mr. Slichter's paper from a more general point of view. It is expected that these two papers will provoke an exceptionally interesting discussion.

Engineers of Atlanta, Ga., will soon form a branch of the American Institute of Electrical Engineers.

At the annual convention of the United Electrical Contractors' Association of New York State, held last week at the Building Trades Club in this city, the following officers were elected to serve for a year: President, Marshal L. Burns, Troy; vice-president, James R. Strong, New York; secretary, Frederick Fish, Rochester, and treasurer, J. C. Stearns, Buffalo.

The *St. James' Gazette* of London calls the attention of professional neologists to the present and rather pressing need of some new verbs. "We want," it says, "popular verbs for several operations introduced by modern science. The X-rays, the Finsen treatment for lupus, the operation of radium for cancer, and what not - what are the words for these? A man is guillotined or hanged, his leg is amputated; he is trepanned. What is it when he is rayed, Finsened, radiumed? We still want a wireless word. 'Marconigram,' which was suggested, seems to have died a natural death. What is the synonym for telephone when one speaks over the instrument to which a phonograph is attached? And have we finally agreed that 'motor' is the verb to travel by automobile?"

At a regular meeting lately held by the St. Louis Electrical Contractors' Association the following officers were elected for the ensuing year: President, E. C. Van-Nort; vice-president, R. Routgell; secretary, Edward T. Cooke; treasurer, William Carroa; sergeant-at-arms, J. H. Lucas.

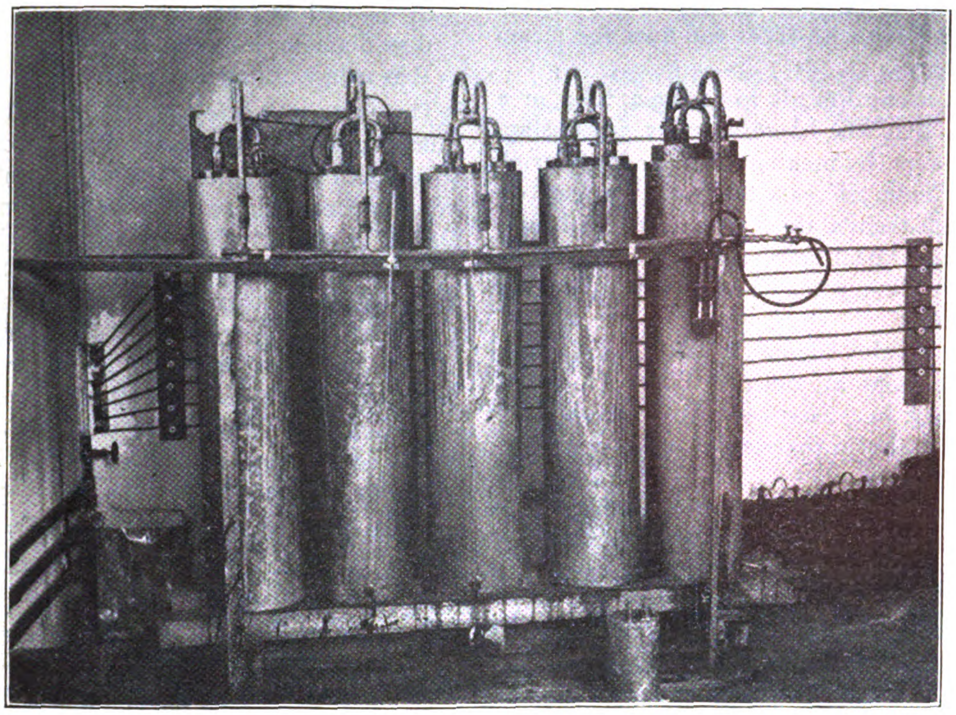
This (Wednesday) evening before the New York Electrical Society Prof. W. G. Goldsborough will discuss the use of electricity in connection with exposition work since the introduction of electric power, starting with the very earliest and most primitive applications. The evolution which has taken place in the making of exhibit installations will be brought out, leading up, as it will, to an estimate of the installations which will be made in the Electricity Building at St. Louis. A general view of the development of electric decorative effects in connection with the interior and exterior illumination of exposition buildings will also be given. The lecture will be profusely illustrated by lantern slides.

THE SCHOOP ELECTROLYZING ACCUMULATOR.

BY EMILE GUARINI.

The above title is a very appropriate one for the invention which is about to be described. The Schoop electrolyzer, after being in operation a short time, differs from the others by the formation of peroxide of lead at the positive pole, making of it an accumulator of small capacity, which fact gives it a certain superiority over all the other kinds of electrolyzers for the industrial production of oxygen and hydrogen gases, because its production of these gases is much greater per kilowatt hour used than is furnished by any of the other processes. Furthermore, it is made by the firm of Kolner A. K. Kumulatoren-Werke, Gottfried-Hagen, one of the oldest German dealers in accumulators. The Schoop accumulator, as manufactured by the firm, possesses in addition to its advantages none of the defects found in others of its kind. It contains no diaphragm, as is usually employed for the separation of the two gases. It consists of a vat or cell which is lined on the inside with lead, and filled with a solution of sulphuric acid having a density of 1.23. There are two curved lead tubes, covered with insulating material on the outside, or two group of tubes, mounted in parallel, which lead into the cell. These tubes are enlarged at their extremities, giving them a bell-shape, so as to present a larger surface for the passage of the current. When these enlarged diameters of the tubes amount to 90 mm. the current, which has a constant flow, is 25 amperes, and the production of oxygen and hydrogen is then respectively 5.22 and 10.44 liters per hour.

The gas pressures depend on the length of these tube electrodes. The pressure in the apparatus, as it is constructed at the present time, is from 60 to 70 cm. of water, and thus need not be mechanically compressed for direct use. The electrical tension is 3.3 to 3.6 volts. Should a 110-volt current be used 30 electrolyzers may be set up in series. The maintenance consists in filling the cells each week with pure water. The discharge pipes are connected to the collecting pipes by means of rubber hose. Usually pressure gauges are fitted to the pipes before they enter the gas holders. While the gases produced are very pure it is considered necessary to wash the oxygen with sulphuric acid for the purpose of taking out what little aqueous vapor it may contain.



View of a Battery Composed of Five Elements of the Schoop Electrolyzing Accumulators.

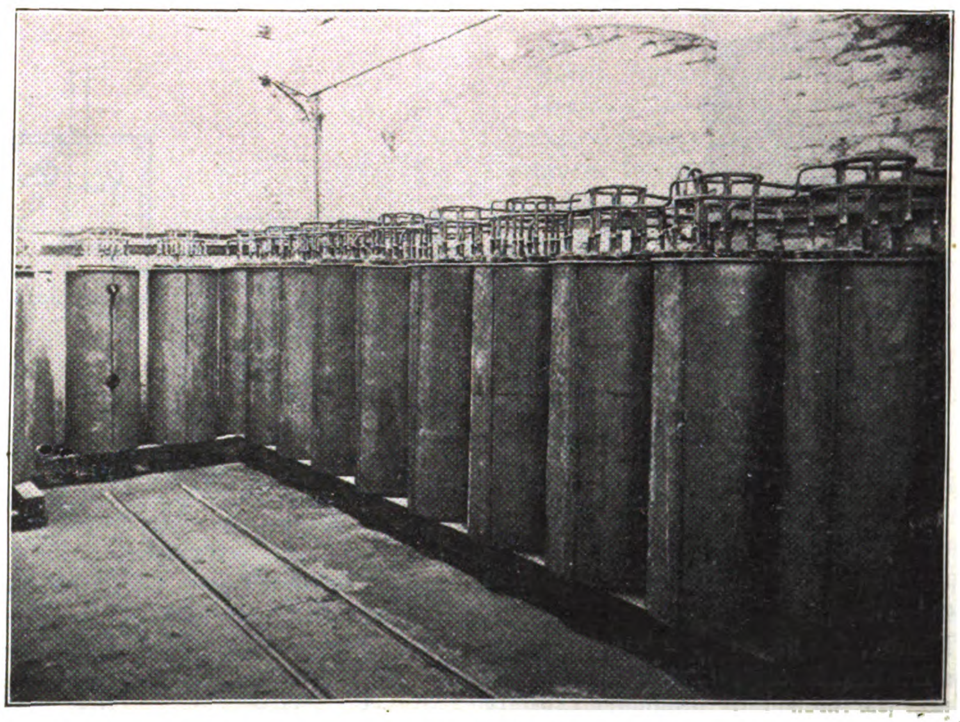
The inventor and the manufacturers claim for this apparatus the following advantages: Absolute sureness of its operation, the exclusion of all danger of explosion, absence of diaphragms and consequently no repairs, an almost chemical purity of the gases, and a reduction in the expense of operation.

From tests already made the oxygen contains impurities of only 1 per cent., that is, 0.8 per cent. of aqueous vapor and 0.2 per cent. of hydrogen; the hydrogen gas produced contains from 2 to 2½ per cent. of foreign gases.

One horse power hour furnishes 48.75 liters of oxygen and 97.5 liters of hydrogen, consequently 6.2 to 6.8 horse power hours on the average is required to produce one cubic meter of the combined oxygen and hydrogen gases.

If we compare the production from this apparatus with that produced by the Garuti process we obtain the following:

Process.	Oxygen in liters.	Hydrogen in liters.
Garuti......	0.083	0.1666
Schoop......	0.067	0.13



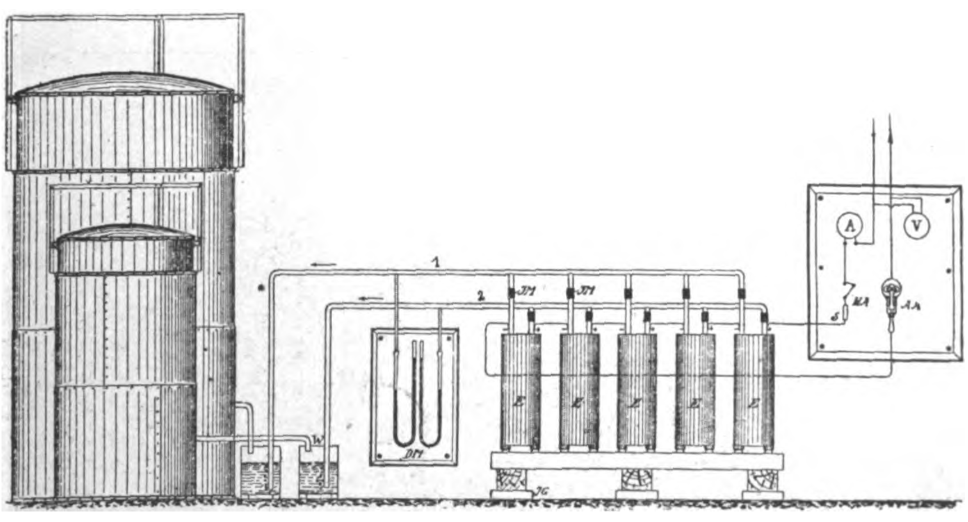
A View of a Large Schoop Electrolyzing Accumulator Battery.

In the meantime it is interesting to note that the Garuti process has advantages over the Schoop process, in that the average of the current is 2.4 volts for the first

and 3.3 to 3.6 volts for the latter, but on the other hand the Schoop process has the advantage over the Garuti in the amperage used. It is further stated that in the production of a cubic meter of the combined gases the consumption of energy in the Schoop process is 6.2 to 6.8 horse power hours and in the Garuti process 5.43 hp. hours.

Soldering Accumulator Connections by Means of Oxy-hydrogen Gas Flame, as Produced by the Schoop Process.

Finally, the process is interesting from the fact that it compensates to a certain extent for the lack of producing capacity which might be imputed to it as well as for other reasons. There is no doubt but that it will contribute to the growth of those industrial processes which require oxygen and hydrogen and which have already commenced to gain a footing.



Diagrammatic View of a Schoop Electrolyzing Installation.

COLLAPSING PRESSURE OF TUBES AND FLUES.

ARTICLE III.

BY W. H. WAKEMAN.

Several years ago the United States Board of Supervising Inspectors adopted the following rules and formula for use in connection with tubes and flues for steam boilers.

It is not difficult to design a tube or a flue that will be safe under any desired pressure, by making it of thick material, but inasmuch as a thin tube is more efficient than a thick one (because it will transmit heat more readily), it should be as thin as a proper regard for safety will admit.

The rules adopted by the United States Inspectors are not only based on correct theory, but have been proved by experiment, also in practice, and are not found wanting.

Some of these formulas are taken from what is known as Lloyd's Register (English authority), but others are apparently original.

Tubes 4 inches and less in diameter and flues not exceeding 6 inches in diameter may be made plain, of any required length, and are allowed to carry 225 pounds pressure per square inch, provided they are properly made of material not less than the thickness prescribed by the following table:

Outside diameter.	Thickness.
2 inches	.095 inch.
2¼ "	.095 "
2½ "	.109 "
2¾ "	.109 "
3 "	.109 "
3¼ "	.120 "
3½ "	.120 "
3¾ "	.120 "
4 "	.134 "
4½ "	.134 "
5 "	.134 "
6 "	.165 "

For flues from 7 to 12 inches inclusive in diameter, and all lengths found in practice, the following formula applies:

$$\frac{806{,}300 \times t^2}{L \times d \times 3} = P.$$

t = thickness in decimals of an inch.
L = length in feet.
d = diameter in inches.
P = safe working pressure.

The factor of safety is evidently 3 in this case, which appears small when compared with the higher factors frequently used in determining safe loads for machinery, etc., but when we remember that for boiler shells the United States Supervising Inspectors allow less than 4 as a factor of safety, when the strength of riveted joint is considered, the factor allowed for flues nearly agrees with it.

Taking flues 16 feet long as before and applying this formula gives the following safe working pressure:

7 inch flue	.24 inch thick,	138 pounds.
8 "	" .26 "	" 142 "
9 "	" .27 "	" 136 "
10 "	" .28 "	" 131 "
11 "	" .29 "	" 128 "
12 "	" .31 "	" 134 "

Of course the collapsing pressure may be found in each case by multiplying the above results by 3, or it may be calculated directly by omitting 3 in the formula.

The next formula may be used to determine the diameter of flue, when the thickness of material, length of flue and safe working pressure are given:

$$\frac{806{,}300 \times t^2}{L \times P \times 3} = d.$$

t = thickness in decimals of an inch.
L = length in feet.
P = safe working pressure.
d = diameter in inches.

Taking for illustration a flue to be made of iron .24 inch thick, length 16 feet, to carry 138 pounds, we find that it may be

$$\frac{806{,}300 \times .24^2}{16 \times 138 \times 3} = 7 \text{ inches.}$$

The required thickness of material may be determined by this formula:

$$\sqrt{\frac{L \times d \times P \times 3}{806{,}300}} = t.$$

The letters refer to the dimensions already explained. Applying it to a case where a flue is to be 16 feet long, 8 inches in diameter, to carry a pressure of 142 pounds, gives the following result:

$$\sqrt{\frac{16 \times 8 \times 142 \times 3}{806{,}300}} = .26 \text{ inch thick.}$$

Where the thickness, diameter and pressure are given the suitable length is determined by the next formula in which the

letters refer to data previously explained:

$$\frac{806,300 \times t^2}{d \times 136 \times 3} = L.$$

If we wish to construct a flue of iron .27 inch thick, 9 inches in diameter, to carry 136 pounds pressure, the required length is easily obtained:

$$\frac{806,300 \times .27^2}{9 \times 136 \times 3} = 16 \text{ feet long.}$$

The four preceding formulas are suitable for application to plain flues of any reasonable length and for the stated diameters (although their limitations are not sharply defined), but if we apply the first of this group to determine the safe working pressure for a flue made of iron .5 inch thick, 20 feet long and 42 inches in diameter, the result is only 26 pounds.

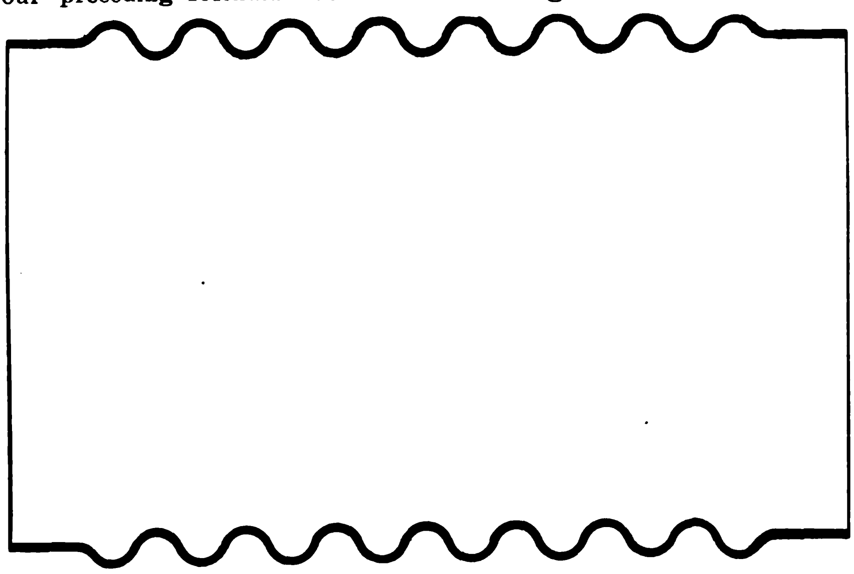

FIG 2.

Such a low pressure is useless for modern practice, but of course the flue would not be made stronger by substituting another formula, therefore measures must be taken for making the flue stronger. This is accomplished by making it in corrugated form as illustrated in Fig. 2, which is known as the Fox furnace flue or Fig. 3, which is the Morison suspension furnace flue. It will be noted that these corrugations add much to the strength of the flue, and another important and valuable feature is that when calculating their safe working pressure it is not necessary to take the length into consideration because the continued corrugations make it independent of the length.

For large flues the corrugations must be not less than 1.5 inches deep, and they must be continued to within 6 inches of the end. Care must always be taken to avoid reducing the thickness of material when making this style of flue.

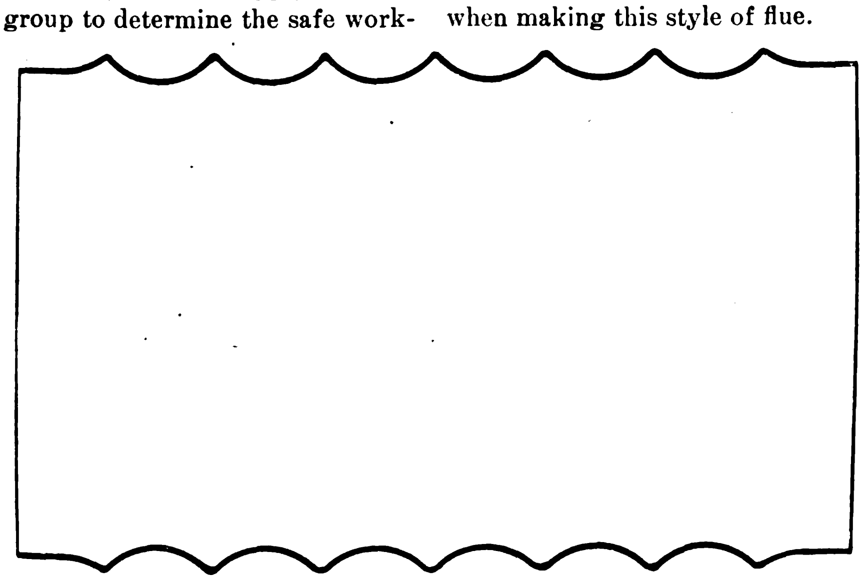

FIG. 3.

When calculating the safe working pressure the average diameter is to be taken. The following formula is given for determining the safe working pressure of corrugated flues:

$$\frac{14,000}{d} \times t = P.$$

d = diameter in inches.
t = thickness in decimals of an inch.
P = safe working pressure.

If a flue is 42 inches in diameter, made of iron .5 inch thick, its safe working pressure is

$$\frac{14,000}{42} \times .5 = 166.5 \text{ pounds.}$$

To determine the diameter of flue for a given pressure and thickness of plate the following applies:

$$\frac{14,000}{P} \times t = d.$$

$$\frac{14,000}{166.5} \times .5 = 42 \text{ inches in diameter.}$$

If the diameter of corrugated flue, and the steam pressure to be obtained, are given, the following formula may be used to determine the necessary thickness of material:

$$\frac{d \times P}{14,000} = t.$$

Applying it to the 42 inch flue to carry 166.5 pounds pressure shows that it must be at least

$$\frac{42 \times 166.5}{14,000} = .5 \text{ inch thick}$$

If large flues that are to carry high pressures are not corrugated they must be made in sections, for experiments have demonstrated that when so designed and constructed it is proper and safe to use the length of section, the same as if it were the total length of flue.

A NEW SURFACE-CONTACT SYSTEM FOR ELECTRIC TRAMWAYS.*

A demonstration of the "G. B." surface contact system was recently given at Ilford, England. As shown in the illustrations, the bare line conductor, consisting of stranded galvanized iron cable, is drawn through plain butt-jointed 5 inch stoneware pipes, and is suspended at convenient intervals by vitrified clay insulators. If found necessary, the electric conductivity of the cable may be raised by including a copper conductor. The galvanized steel pivots of the insulators are carried through one side of the glazed pipe conduit, and are all electrically connected together and with the track rails. This is to insure a direct path to the rails for any possible leakage current from the cable, thus practically preventing a serious difference in pressure between the studs and the rails due to surface leakage on the clay insulators. Although the total depth of excavation does not exceed 19 inches in standard practice, even this depth may be reduced by 6 inches or 7 inches for special purposes. As seen from Fig. 2, the whole conduit is embedded in concrete.

*From the "Electrician," London.

Access boxes, placed at intervals of from 200 yards to 400 yards along the track, consist of cast-iron bodies with manganese covers. The two cable ends, entering a box at opposite sides, are led to terminal bars, mounted on insulators within the box. Drainage pipes, leading from the

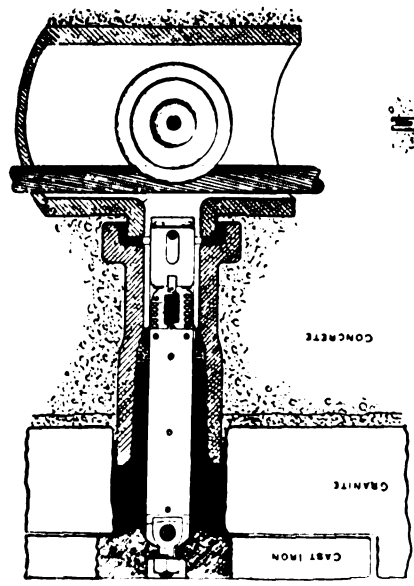

FIG. 1.—CROSS-SECTION AND LONGITUDINAL SECTION OF STUD.

bottom of these boxes, conduct away any water which may accumulate in the earthenware pipes. Every 7 feet 6 inches —corresponding to the distance between studs—a short vertical earthenware tube is cemented to the main horizontal pipe (Fig. 1). Into this vertical portion of the pipe system the laminated stalk of the stud is let, the upper part of the intervening space between it and the tube being subsequently filled up with bitumen, a packing of jute yarn preventing this material from falling through. A loosely fitting contact plunger, consisting of a laminated body and a carbon contact piece, slides in the brass-lined fork of the stalk, as indicated in Fig. 1. It is electrically connected to the stalk by flexible copper conductors and is held up from the cable against the force of gravity by an insulated phosphor-bronze spring, the separating distance being about $\frac{5}{16}$ inch. The stalk is connected to the cast-iron stud by a somewhat flexible joint, but this does not prevent its making good electrical and magnetic contact. A recessed granite block receives the stud which is level with the track and whose surface measures 2½ inches by 14 inches. By directing the flame of a blow-pipe against the stud, the bitumen beneath is made to melt and the stud as a whole may be withdrawn, this operation occupying, it is said, but seven minutes. In addition to the ordinary standard equipment, each car is provided with a magnet rigidly suspended beneath the car and a battery of accumulators. It may be mentioned that the accumulators serve for starting only, being charged up during ordinary running. One pole of the magnet is in the form of two parallel iron bars, and is suspended at a distance of about 2 inches above the center of the track. Between these two bars are a number of iron tongues (Fig. 2) suspended by springs, but free to move a considerable distance up and down. These are all connected at their lower ends by one flat chain belt (not shown in the illustration), about ⅜ inch wide, which is kept parallel to the track at a distance of approximately ⅝ inch by the springs and tongues referred to. In order to have a continuous supply of current, the belt is made longer than the distance between any two studs.

As the car comes over each stud both the flexible chain belt and the sliding

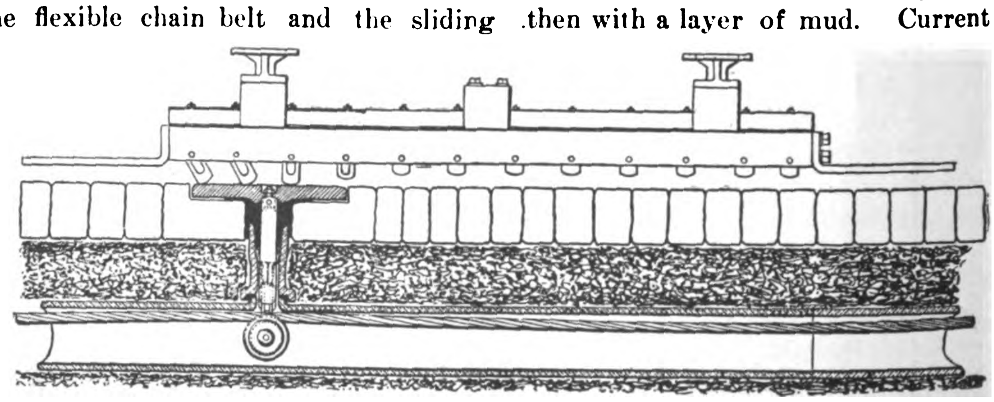

FIG. 2.—CURRENT-COLLECTING DEVICE.

plunger are attracted downwards, and the former, on coming in contact with the stud, completes the electric circuit. It is stated that the net force with which the plunger, weighing 6½ ounces, is drawn downwards, is equivalent to the weight of 6 ounces at the beginning, increasing to about 16 ounces when the carbon contact touches the cable. If a non-magnetic cable is used, the figures are given as 3 ounces and 6 ounces respectively.

The gauge of the trial track, which was one-fifth mile in length, was 4 feet 8½ inches, and the paving consisted of granite in bitumen, granite in cement and hard wood. The steepest gradient was 1 in 32, the sharpest curve having a radius of 54 feet. A double-deck car, with a total seating capacity for 54 passengers and fitted with two 25 hp. Walker motors and Dick-Kerr series-parallel controllers had been fitted up with the auxiliary equipment necessary for the new surface-contact system. Its weight, fully equipped, was stated to be 10 tons. When running empty round the track, the current taken by the car varied between 20 and 35 amperes, the latter current corresponding to the steepest incline, the pressure being kept constant at 500 volts. The leakage of the experimental track was measured and found to be 0.05 ampere; and it may be mentioned that the ground upon which the track was laid was very moist. When a bucket of water was thrown on the track, the leakage of current between the rails and a live stud began with 0.5 ampere, and then fell gradually. In order to show the current-carrying capacity of the contacts, the car brakes were applied and the car set in motion. By this means a current of about 95 amperes was taken through the studs.

The energy absorbed for exciting the magnets was measured during the tests, and amounted to 325 watts. On one occasion, a stud was thickly smeared with mud, and the car slowly brought over it; this, however, did not prevent current being successfully picked up. Another stud was covered with a newspaper, and then with a layer of mud. Current was also picked up in this case, that portion of the paper only being torn by the collecting chain which was directly above the stud.

In case a stud should remain alive after the chain belt has passed, the supply is interrupted by means of chains, fixed to the end of the car and trailing on the track, coming in contact with the live stud and causing a maximum cut-out on the car to operate.

The metric system has been adopted by the Parliament of New Zealand.

ELECTRICAL STATION PRACTICE.

ARTICLE XXI.

BY W. H. RADCLIFFE.

Alternating current voltmeters although similar in outward appearance to direct current voltmeters, are designed to operate on a different principle. This fact would impress itself very noticeably were one attempting to measure the pressure of an alternating current with a voltmeter of the direct current type, for no matter how high the voltage there would be no deflection of the pointer owing to the rapid reversals of the alternating current.

Voltmeters of the alternating current type depend for their operation on the magnetic effect of the current alone, so that they never contain permanent magnets. In the matter of details, however, they differ considerably according to the manufacturer. In one type there are two coils of wire wound in opposite directions on cylindrical spools which are mounted end to end, and these serve in place of the permanent horseshoe magnets in the instruments previously described. Between the spools in each meter is pivoted a fine wire coil which is provided with pointer and springs as in the case of the direct current voltmeter. The three coils are joined in series with each other and then in series with a high resistance wire such as was employed in the direct current instrument. The lead from the resistance wire runs directly to the left-hand binding post, while the remaining lead from the coils is usually connected with an adjustable resistance used for temperature corrections, and then through a key to the right-hand binding post.

It makes now but little difference in which direction the current is flowing since the relation between the lines of force of the two fixed coils and those of the movable coil is always such as to deflect the pointer in the same direction over the scale. The reason for this lies in the fact that the three coils are connected in series, so that when the current changes direction in one of them it changes direction in all three. The reversals of an alternating current are always so rapid that there is practically the same effect produced in the meter as would be done by a direct current of nearly the same strength; there is therefore a steady deflection of the pointer at all times the meter is connected in circuit. From what has just been stated it is evident that a voltmeter thus designed to measure the pressure in an alternating current circuit would also be capable of measuring the voltage in a direct current circuit, although, as previously mentioned, a direct current voltmeter would not measure the pressure in an alternating current circuit.

It has been stated there is usually introduced in this type of alternating current voltmeter an adjustable resistance for temperature corrections. This resistance is varied by turning a knob to which an index projecting over a circular scale graduated in Centigrade degrees is attached. The resistance itself is contained within the case of the meter, but the knob, index and scale are mounted on the face of the instrument. A small Centigrade thermometer is also mounted on the face of the meter to aid in the adjustment. To correct for a variation in the resistance of the voltmeter due to change in temperature, it is merely to note the reading on the thermometer and then turn the knob until the index points to this same number of degrees on the scale beneath it. This movement of the knob cuts in or out of the voltmeter circuit the necessary amount of the adjustable resistance to compensate for the change due to a variation in the atmospheric temperature.

In another type of alternating current voltmeters largely used, a coil of fine wire is connected between the terminals of the meter, and the magnetic attraction produced by a current passing through this coil of wire for a laminated iron core or plunger to which the pointer is attached, is a measure of the voltage applied to the terminals of the instrument. As in the other meters described, springs are here also used; one of them is fastened to the plunger and draws it, together with the pointer attached, back to the zero position where there is no current and, therefore, no voltage applied.

The capacities of the alternating current voltmeters in general use are 3, 7.5, 10, 12, 15, 20, 60, 75, 120, 150, 300 and 600 volts, but these capacities may each be increased by the use of a multiplier in the same manner as previously explained for direct current voltmeters. Station voltmeters are usually bolted to the switchboard by means of four iron supports mounted on the back of the instrument; two of these are fastened toward each side of the case. Under certain conditions, however, as in paralleling of alternators, it is convenient to have the alternating current voltmeters mounted on swinging brackets at the side of the switchboards. The voltmeter may then be swung around in any desired direction so as to enable the attendant to keep informed of the voltage while switching in each additional alternator.

The ammeter or instrument for measuring the current strength has not as yet been considered in detail, so the direct current type of this meter will now be taken up. The outward appearance of a direct current ammeter is not dissimilar from a direct current voltmeter except that the binding posts are larger, and the portable instruments are not provided with keys. Within the metal case there are also many points of similarity. In the Weston direct current portable ammeter there is a permanent horseshoe magnet of precisely the same shape and size as the one described in connection with the Weston direct current portable voltmeter. There is also a fine wire coil to which a pointer and springs are attached as in the previous case, and a soft iron core is permanently fixed in the same manner within this coil for strengthening the magnetic circuits of the horseshoe magnet and of the fine wire coil. Owing to the different positions occupied by the two instruments in circuit, however, the remaining details in their construction differ considerably. The ammeter must necessarily be connected in series with the circuit to measure the current and so must contain a low resistance else the current will be needlessly wasted thereby, whereas a voltmeter being bridged across the circuit in order to obtain its pressure must contain a high resistance so as to shunt as little of the current as possible.

The circuit through a direct current ammeter is as follows: From one of the binding posts a lead connects with a copper plate. Directly beneath this plate and parallel to it is mounted a second copper plate similar in every respect to the one previously mentioned; this plate is also joined by a lead with the remaining binding post of the meter. Connecting the one plate with the other are a number of short circuits of fine insulated wire in parallel, which for support are wrapped non-inductively around the yoke of the permanent horseshoe magnet. The fine wire coil carrying the pointer is also electrically connected across these two plates, and the scale over which the pointer projects is graduated after so proportioning the number of the auxiliary parallel circuits between the plates as to allow the necessary amounts of current through the fine wire coil to produce the proper deflections. The atmospheric temperature correction for this type of ammeter is, for a range of 35 degrees above or below 70 degrees Fahrenheit, less than 1 per cent. and may therefore be neglected.

Inasmuch as the entire current of the circuit must pass through the ammeter in order to be measured, conditions are favorable for the development of a considerable amount of heat within the in-

strument, and as this heat tends to increase the resistance of the interior wiring there is an error introduced which varies according to the strength of the current in amperes and the time during which it is passing through the meter. In ammeters whose capacities are .75, 5, 15 or 25 amperes the currents passing through the instruments are so small that although the meter be left in circuit for an indefinite length of time, the errors introduced in each case will be less than 1 per cent. and therefore negligible. In an ammeter having a capacity of 50 amperes, the error thus introduced will be less than 1 per cent. if connected continuously in circuit with a current not exceeding three-quarters this capacity. An ammeter of 100 amperes capacity may be used indefinitely in circuit with less than 1 per cent. error up to one-half its capacity, and for five minutes at three-quarters capacity without exceeding the 1 per cent. limit. The 150 scale ammeter may be left in circuit for an indefinite length of time at one-third its full capacity, and for three minutes at one-half its full capacity, with a negligible error. Ammeters of 200 and of 300 ampere capacities must not carry more than one quarter these respective number of amperes continuously if the readings are to have an accuracy within 1 per cent., nor more than one-half these respective number of amperes for three minutes if the same degree of accuracy is desired. In order to cut or shunt the ammeter out of circuit when not in use, it is customary when wiring the instrument in place to introduce a switch as a shunt across it; this switch is kept closed except when a measurement is being taken.

When currents larger than 300 amperes have to be measured, ammeter shunts are generally employed, although ammeters up to 500 amperes capacity are manufactured. An ammeter shunt consists of a number of strips of alloy mounted parallel to each other in two copper blocks. Each of the blocks contain two binding posts, one of which serves for the main conductor of the circuit and the other for a lead to the meter. The meter used in this connection is designed along the lines of a voltmeter, rather than those of an ammeter; in fact, the instrument might well be termed a low reading voltmeter, or a voltmeter in which the high resistance coil is replaced by one of low resistance. The meter is graduated by varying the length of the resistance coil until the deflections of the pointer on the scale of the instrument agree with the number of amperes passing in the main circuit as measured on another instrument. After the meter is once graduated, it is, of course, used only in connection with the shunt and a special pair of leads belonging to it, for measuring current.

The principal advantage of the ammeter shunt is that the strips of alloy of which it is composed being surrounded on all sides with air, radiates most easily any heat developed therein by the current, so that its resistance does not vary perceptibly with the number of amperes passing through it; therefore, the voltage operating a meter used in connection with the shunt is more directly proportional to the current than in most other ammeters. Owing to this fact, currents up to and including 10,000 amperes may accurately and easily be measured. In the handling of this meter it is important to guard against passing the current in the main circuit directly through it, that is without the use of the ammeter shunt, since the resistance of the meter is generally so low that the pointer will give a full scale deflection on less than the five-hundredth part of a volt across its terminals. It is well, therefore, always to wire a switch across it so that it may be shunted out of circuit when not in service.

Station ammeters of the direct current type must usually have capacities above 300 amperes, so the majority of them are used in connection with ammeter shunts. The meters themselves are then constructed on the principle of a low reading voltmeter as previously explained. The outward appearance of direct current station ammeters is not unlike that of direct current station voltmeters. The working parts are enclosed within a cast-iron case which, as before, acts as a shield guarding the instrument against magnetic influences of a foreign nature. There is also an opal glass scale illuminated from the rear by an incandescent lamp, but the normal index mentioned as a part of the station voltmeter is quite unnecessary in the case of a station ammeter. The meter is fastened to the switchboard by means of four iron supports attached to the back of the instrument in the same manner as to the station voltmeter.

Owing to the similarity between the construction and the principles of operation of direct current meters, many of the rules previously given for the handling of direct current voltmeters apply with equal force in the case of direct current ammeters. Those precautions to which special attention should be given are the following: An approximate idea of the number of amperes to be measured before introducing the ammeter in circuit. The proper direction of the current through the meter so that the pointer is deflected over the scale. The straightening of the pointer if more than two-tenths of a division off the zero mark. Securely fastening the wires or cables which connect the meter in circuit so that they will not, if pulled by accident, cause the meter to fall. Placing the instrument away from disturbing magnetic influences. Careful handling of the meter when moving it from place to place, or when setting it down. Reading deflections of the pointer to tenths of a division. In portable instruments, making use of the mirror for obtaining accurate readings, and tapping the case of the meter if the pointer has difficulty in coming to rest.

Ammeters which are not used in connection with shunts, and yet which are permanently connected in circuit at or near their maximum capacities, not only suffer in accuracy from the heat developed within their windings, as previously explained, but are also affected by any heat that may be generated at the contacts between the binding posts of the meters and the wires connecting therewith. To reduce as far as possible errors in the observations arising from the latter cause it is advisable to employ for the part of the circuit connecting with the meter, wires of a larger diameter than would actually be required for the number of amperes carried, or else to substitute for these wires cables without terminals; the latter conductors, owing to the relatively large amount of surface exposed to the air, afford a high degree of radiation and therefore maintain low temperatures at the points of connection.

THE INTERNATIONAL ELECTRICAL CONGRESS.

According to the present indications the International Electrical Congress, to be in session at St. Louis September 12-17, will be one of the most successful that has yet been held, both with respect to the number of adhesions and to the value of the transactions.

Up to date about 3,550 circulars letters of invitations to join the Congress have been issued to persons or associations in North America. From these 875 acceptances of membership have been received. About 350 similar circular letters of invitations have been recently sent to other countries. It is intended to issue in all about 5,000 invitation circular letters in American and about 6,000 in foreign countries, It is expected that many persons will join the Congress, both in America and abroad, who do not expect to attend the sessions in St. Louis, in order to secure a copy of the Transactions, which will form one and perhaps two

large octavo volumes. Collection of fees has commenced, and upon receipt of a fee the member will be forwarded a certificate of membership. The certificate is 8½ inches by 11 inches in size, and printed on heavy paper of excellent quality.

Recently 280 special letters of invitation have been issued on behalf of the committee of organization to prominent electricians and electrical engineers, signed by the president and the general secretary of the committee, requesting papers for the Congress in the various sections. Of these, 146 have been sent to foreign authors, and 134 to American authors. There has not been time to receive replies from more than a few foreign authors, but 21 acceptances have up to date been received from abroad, and 46 acceptances from North America. Sixty-seven papers have thus already been promised for the Congress, and the number is steadily increasing. A considerable further number of invitations to contribute papers have yet to be issued. It is hoped that the Congress will convene with a full programme in each section, and that at least half of the papers may be from foreign countries. According to the plans of the committee, papers for the Congress programme are specially invited, but papers voluntarily offered will be submitted to the officers of the sections to which the papers belong, and may be included in the programme by invitation at their request, if the subjects are desirable, and if the schedule allotted to each section will permit, it being the desire of the section officers to secure and offer the best possible programme and presentation.

Petitions from the Congress committee of organization and from the president of the American Institute of Electrical Engineers have been filed with the Department of State at Washington, through the Department of Commerce and Labor and the National Bureau of Standards, urging that the various foreign Governments should be invited to appoint official delegates to the Congress. The lists of such delegates to be invited is in accordance with the lists allotted to the various countries at the Paris Congress of 1900, and the Chicago Congress of 1893. Including the United States, the lists comprise 56 official delegates. Information has been received that these petitions have been granted, and that the State Department on December 17 last, instructed the diplomatic officers of the United States abroad to extend an invitation to foreign countries to be represented at the Congress by delegates.

Arrangements are being made with a view to perfecting plans of co-operation between the Congress and electrical societies and associations in various parts of the world. Invitations have already been extended to the Congress members to visit places of electrical interest on the journey to or from St. Louis.

The committee of organization of the Congress consists of Elihu Thomson, president; A. E. Kennelly, general secretary; W. D. Weaver, treasurer; Bion J. Arnold, vice-president and chairman of executive committee; C. F. Scott, Dr. S. W. Stratton, Prof. H. S. Carhart and Prof. W. E. Goldsborough, vice-presidents.

The following section officers have been appointed by the president and have done much work in organizing their sections:

Section A, General Theory—Prof. E. L. Nichols, Cornell University; Prof. H. T. Barnes, McGill University.

Section B, General Applications—Prof. C. P. Steinmetz, Schenectady; Prof. Samuel Sheldon, Brooklyn.

Section C, Electrochemistry—Prof. H. S. Carhart, University of Michigan; Carl Hering, Philadelphia.

Section D, Electric Power Transmission—C. F. Scott, Pittsburg; Dr. Louis Bell, Boston.

Section E, Electric Light and Distribution—J. W. Lieb, Jr., New York; G. S. Dunn, New York.

Section F, Electric Transportation—Dr. Louis Duncan, Massachusetts Institute of Technology; A. H. Armstrong, Schenectady.

Section G, Electric Communication—F. W. Jones, New York; Bancroft Gherardi, New York.

Section H, Electro-Therapeutics—Dr. W. J. Morton, New York; W. J. Jenks, New York.

All communications should be addressed to the general secretary, Dr. A. E. Kennelly, Harvard University, Cambridge, Mass.

National Electric Light Association.

One or the most interesting and valuable portions of the volume of Transactions which the National Electric Light Association is about to issue is the report with cuts in colors on decorative and sign lighting. If for nothing else the members are likely to prize this volume on receiving it. Mr. Arthur Williams, the reporter on the subject, has been appointed to take up the matter again this year in a second report, and proposes to handle the subject in a somewhat different manner, adding to illustrations the ideas and opinions of central station men concerning advertising signs, and selecting instances in which decorative lighting of that character has been productive of increased trade and revenue to the users. He is now collecting such data and all of our readers interested in the subject should communicate with him at the offices of the New York Edison Company.

NORTHWESTERN ELECTRICAL ASSOCIATION CONVENTION.

The Milwaukee Meeting Well Attended--A Number of Important Papers Read and Discussed—T. F. Grover, of Fond du Lac, Elected President.

The twelfth annual convention of the Northwestern Electrical Association was held at the Hotel Pfister, Milwaukee, Wis., Wednesday, Thursday and Friday, January 20, 21 and 22.

The convention was called to order at 12 o'clock on the opening day by President F. W. Bowen, and at the request of Secretary Mercein the delivery of the president's address was postponed until the afternoon session.

The secretary presented his report which was accepted, and the convention adjourned until 1:45 P.M.

WEDNESDAY AFTERNOON SESSION.

The convention was called to order at 1:50 P.M., and the president then read his address as follows:

PRESIDENT'S ADDRESS.

Gentlemen of the Northwestern Electrical Association:

It is with the utmost pleasure that I welcome and greet you at this the 12th annual convention of this association, which will, I hope, if such a thing be possible, be of even greater interest to our membership than any which has preceded it. I would, however, expressly disclaim responsibility for such a happy result, but on the contrary place the credit for it where it is due, with our worthy and esteemed secretary.

Having thus unburdened my mind and set myself right on the matter of the programme to be presented for your consideration, I wish now to express my regret for the fact that one of the features which I had hoped to make prominent at this convention will not be among the possibilities at this meeting of our association; I now refer to the "Question Box" and "Wrinkle Department," which I had hoped to make a matter of personal work during the past year, but have been

prevented by the fact that twice within the year 1903 our central station has been destroyed by fire, thus entailing much additional work upon our force and seriously interfering not only with our own service and business, but also with whatever plans I had for the work of the Northwestern Association.

It is not, however, of personal matters that an address of this kind should treat, and I beg your indulgence for their mention.

Again returning to the subject of the programme, I would say that it has been most carefully considered and will cover many matters that will be of extreme interest to our members, both active and associate, and, unless some of our contributors fail us, we shall cover a wide field of information, both theoretical and practical, and I trust that the discussion of the papers presented will be active and searching, as it is in these discussions that the true value of the papers presented is to be found; therefore, do not let your modesty hold you back in these discussions, but add each your mite to the value of these proceedings by bringing forward any point which may suggest itself to you.

It is held by some that the better way to get at the "meat" of a paper is by the prearranged discussion of the papers by those who may perhaps be thought the most competent, but I am of the opinion that where this method is in vogue, the membership generally does not get sufficiently interested to bring forward many points that might suggest themselves, and the "cut and dried" method of discussion gradually undermines the active interest of the members generally and destroys in great measure the usefulness of such associations as ours and interest in the proceedings wanes.

I am further of the opinion that we have within our ranks men and minds, which, if not stifled by an air of prearrangement, are competent enough and bright enough to discuss any paper offered by men who are technical in their respective lines and to bring out many obscure points, and thus make the papers of the more value to all of us; again, therefore, let me urge upon all the necessity of discussion if we are to get full values, and let each contribute his share.

It is unnecessary to add that the commercial side of every proposition is the one which most appeals to the central station man, and it is to be expected, therefore, that those side lights will be thrown on the papers to be read, and it is right and proper that it should be so. It is, of course, from the technical side that the papers are written, and it is from the operative side that they are in measure discussed.

During the year which has but just passed over into history there has been much done which is of interest in our profession, though no startling discoveries or innovations have been brought forward, if possibly we may except the mercury vapor lamp; but still the year has witnessed better development of many appliances, and it is now more than probable that each future year will add to this general betterment, though with less of novel ideas to attract and possibly, as in the past, to discard. The general principles of our business seem to be better settled and more fully grounded and the lines of machine building seem to have reached their limit for a considerable time at least, and therefore the central station man is very much nearer a standard than ever before. This is a hopeful sign for our chosen business and it is probable that our depreciation accounts will be the gainer from the fact that the various apparatus used will not be found, as in the past, to be obsolete almost as soon as installed.

The twin subjects of taxation and municipal ownership are and always will be with us. I am, however, very much of the opinion that both are more likely to be met more in the spirit of fairness than in the past. I have no recommendations in the nature of a cure at all to make upon these important subjects, and can only say that as the nature and hazards of our business are more understood by the general public we will be better treated by the same public through their chosen representatives. Let us at all times treat them with fairness and strive by our good treatment of the public, from whom we receive our franchises, to merit their good will, give them the best possible service for the least possible cost to them and we will make friends instead of enemies, or, at best, doubtful friends, as many seem to think us. The standardization, of which I have spoken, will ultimately be the means of enabling central stations to manufacture their output commodity at a cost which will enable them to supply the public at terms that will, while selling their output at a non-restrictive price, yet realize a fair and equitable profit on their sales, which from the very fact that they are selling standard goods, will increase by the application of their product to many new uses by the consumer.

This then will still further operate to make friends of the general public and thus in a measure silence the popular clamor for high and still higher taxes upon our industry and for the establishment of municipal, lighting and power plants.

I shall not here inflict upon you my personal views as to the rights of the municipal authorities to enter upon a commercial venture in competition with their fellow citizens, but in some occult or obscure way our business seems to be a target, though why other lines, such as provisions, fuel and other public necessities, escape such proposal on their part does not make itself entirely clear to me.

I find that I have already exceeded the limit of time which I had proposed and which is of more value if used for other purposes of this convention, and will therefore again welcome you and thank you for your kind attention and forbearance, and we will now take up the regular business before this assembly.

The address was received with great applause.

The president appointed the following committees: Nominating—R. N. Kimball of Kenosha, H. W. Frund of Vincennes and P. H. Korst, of Janesville. Membership—J. H. Harding of La Porte, W. H. Schott, of Chicago and Irving P. Lord of Waupaca.

Several applications for membership were then presented and referred to the membership committee.

Reports were received from several committees appointed at the last session, all reporting progress—the legislative committees reporting that no legislation had been passed the last year adverse to the association's interests.

The president then called for the paper by Mr. W. H. Schott, of Chicago, on "Central Station Heating." Mr. Schott read his paper and it brought out a long discussion, nearly all the members participating.

The next paper called for by the president was on "Coil Windings for Electrical Purposes," by Messrs. Richard Varley and Charles R. Underhill. The paper was read by the latter gentleman.

Secretary Mercein stated that Mr. Underhill is the chief engineer of the Varley Duplex Magnet Company, and came all the way from Providence, R. I., to read the paper, and on motion a vote of thanks was extended to him by the association.

The paper on "The Electrolytic Rectifier and Interrupter," by Mr. W. Scheidel, was read by the secretary, the author not being present.

The next paper read was by Mr. George C. Keech on "Incandescent Lamps in General—Their Smashing Point in Particular."

A lively discussion followed the reading of this paper, many valuable points being brought out.

An adjournment was then taken until 10 o'clock next day.

THURSDAY—MORNING SESSION.

The convention was called to order at 10 A. M. by the president. He said: "The first item on our programme this morning is questions and answers, but instead we will take up Mr. Waters' paper on "Double Current Generators."

Mr. Waters did not read his paper in full, but said: "I propose to deal with this question of double current generators more from the standpoint of the manufacturer than from that of the central station engineer," and stated that it was the old question of alternating vs. direct current.

The President—We will now listen to a paper on "Rectifiers," by Prof. C. F. Burgess.

The paper was discussed at length and the discussion was concluded by the president saying: "I am firmly of the opinion that some kind of a rectifier is to be the future solution of the automobile problem."

At this point the nominating committee reported the following names for officers and directors for the next year:

President—T. F. Grover, Fond du Lac.

First Vice-President—George H. Lukes, Evanston.

Second Vice-President—F. A. Daniel, Menominee.

Secretary-Treasurer—Thomas R. Mercein, Milwaukee.

Directors—W. H. Schott of Chicago, D. C. Jackson of Madison and H. Almert of Oak Park.

On motion of Mr. Lord the chairman of the committee was directed to cast the ballot of the association for the officers named.

Mr. Grover, the president-elect, was escorted to the chair, and after thanking the members sincerely for the honor conferred upon him retired to allow President Bowen to serve until the end of the meeting.

On motion of Mr. Cutter it was decided to hold the summer meeting in September in St. Louis, to meet with other electrical associations and electrical people, the date to be left to the executive committee.

The convention then adjourned until 1:45 P. M.

THURSDAY—AFTERNOON SESSION.

The convention was called to order by the president and he requested Mr. J. R. Kimball of the Walker Switchboard Company to read the paper prepared by Mr. John J. Gibson on "Standard Practice in the Use of Alternating Current Electrical Apparatus." Mr. Gibson was unable to be present, but the members discussed the paper.

A motion was made and unanimously carried that Secretary Mercein be sent to Boston in May as the association's representative at the annual meeting of the National Electric Light Association.

Mr. J. M. S. Waring then read his paper on "Storage Batteries for Small Central Stations," which he illustrated with lantern slides, and this was followed by a paper on "Steam Turbines," by Mr. James Lyman.

At the conclusion of Mr. Lyman's paper Prof. R. A. Milliken delivered a very interesting lecture on radium.

The lecturer was loudly applauded when he concluded and the convention adjourned until the following morning.

FRIDAY'S SESSION.

The convention was called to order by the president at 10 A.M., but there being no business to transact the president declared the convention adjourned sine die.

New York Electrical Society.

The 240th meeting of the Society will be held at the American Institute, 19 West 44th street, this (Wedensday) evening, January 27, at 8 o'clock.

Prof. W. E. Goldsborough, chief of the Department of Electricity, World's Fair, St. Louis, will lecture on "The Influence of Electricity upon Expositions."

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 19, 1904.

Electric Railways and Appliances.

749,716. Rail-Contact-Shoe, George W. Brady and Lawrence R. Jones, Wheaton, Ill. Filed Jan. 26, 1903.

749,795. Trolley-Stand. James Kermath, Detroit, Mich., assignor, by direct and mesne assignments, to the Eclipse Manufacturing Company. Filed Oct. 9, 1903.

749,916. Trolley for Overhead-Electrical Conductor Systems. Eugenio Cantono, Rome, Italy. Filed Aug. 3, 1903.

749,939. Railway Signaling Apparatus. John F. Mickey, Frank T. Bailey and Joseph J. Noppenberger, Baltimore, Md. Filed Aug. 1, 1903.

750,117. Electrical Operated and Controlled Railway Signal. Robert D. Peters, Knox, Ind. Filed Nov. 21, 1902.

750,139. Electrical Controller for Railway-Cars. Harlan P. Wellman, Ashland, Ky. Filed Nov. 19, 1903.

Electric Lights and Appliances.

749,998. Electric Tube-Lamp. Daniel M. Moore, Newark, N. J. Filed Jan. 22, 1903.

749,999. Electrode for Electric Tube-Lamps. Daniel M. Moore, Newark, N. J. Filed Feb, 26, 1903.

750,198. Socket for Incandescent Lamps. Owen E. Kenney, Toledo, O., assignor to the Yost-Miller Company. Filed June 16, 1902.

Electrical Machinery and Apparatus.

749,835. Electrochemical Switching Mechanism. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed May 29, 1903.

749,841. Portable Electrically-Driven Drilling Apparatus. George F. Campbell and Stanley T. Isherwood, Bootle, Eng. Filed Nov. 26, 1901.

749,949. Indicating-Dial for Snap Electric Switches. Charles G. Perkins, Hartford, Conn. Filed Oct. 29, 1903.

750,009. Electromagnetic Gearing. Eric Thordon, Pittsburg, Pa., assignor to the Westinghouse Machine Company. Filed Feb. 6. 1903.

750,012-750,013. Fire-Alarm Mechanism. Leonidas G. Woolley, Kenton, O., assignor to Asa C. Cooney, same place. Original application filed April 27, 1903. Divided and this application filed July 6, 1903.

750,039. Ruhmkorff Coil. Richard Varley, Providence, R. I., assignor to the Varley Duplex Magnet Company. Filed Aug. 21, 1903.

750,040-750,041. Vibratory Circuit-Controller. Richard Varley, Providence, R. I., assignor to the Varley Duplex Magnet Company. Filed Oct. 19, 1903.

750,068. Electrically-Operated Railway Gate. Max Spinrad and Hans Buechting, New York City. Filed June 16, 1903.

750,115. Automatic Electric Pump. Francis L. Orr, Thurman, Ia., assignor of one-half to William W. Keyser, Percival, Ia. Filed Sept. 9, 1903.

750,207. Electromagnetic Brake. John S. Lockwood, Kansas City, Mo. Filed June 23, 1902.

750,239. Electrically-Heated Soldering-Iron. William J. Bowen, Cleveland, O., assignor to the Williams-Abbott Electric Company, same place. Filed Aug. 17, 1903.

750,244. Fuse for Electric Circuits. Elwood C. Phillips, Chicago, Ill. Filed Jan. 9, 1903.

Telephones and Telephone Apparatus

749,798. Central-Energy Telephone System. Kempster B. Miller, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Dec. 19, 1900.

749,814. Relay Device. John P. Downs, Cleveland, O assignor to the North Electric Company. Filed May 7, 1902.

749,824. Telephone-Exchange. Nils E. Norstrom, Chicago, Ill., assignor of two-thirds to John Anderson Salina, Kan., and M. E. Richardson, Sterling, Kan Filed Nov. 23, 1900.

749,977. Telephone-Hook Switch. Ernest E. Yaxley, Chicago, Ill., assignor to the American Electric Telephone Company. Filed June 12, 1901. Renewed Dec. 23, 1903.

749,982. Electrical Signaling System. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company. Filed Dec. 19, 1901.

Miscellaneous.

749,769. Electric Sanitary Closet. James H. Wilson, Lowell, Mass. Filed Oct. 23, 1902.

749,775. Electrostatic Relay, Dan La Cour, Copenhagen, Denmark. Filed Feb. 7, 1903.

749,785. Battery-Plate. Oskar Frank, Detroit, Mich., assignor to Levi J. Lennox and the Michigan Storage Battery Company, same place. Filed May 2, 1903.

749,791-749,792. Means and Method for Reproducing Electrical Variations. Peter C. Hewitt, New York City, assignor, by mesne assignmets to the Cooper-Hewitt Electric Company. Filed May 16, 1902.

749,793. Regulator for Gas or Vapor Electric Apparatus. Peter C. Hewitt, New York City, assignor, by mesne assignments, to the Cooper-Hewitt Electric Company. Filed May 16, 1902.

749,813. Portable X-Ray Apparatus. Eugene W. Caldwell, New York City. Filed Jan. 16, 1903.

749,854. Means for Converting Faint Vibrations Into Electrical Energy. William H. Fahrney, Chicago, Ill. Filed Jan 10, 1903.

749,855. Process of Producing Electrodes for Storage Batteries and Electrode. Frederick A. Feldkamp, Newark, N. J., assignor to the Electra Manufacturing Company. Filed May 19, 1903.

749,867. Method of Securing Electric Wires. Alexander Kline, Jersey City, N. J. Filed March 31. 1902.

749,868. Power Transmission Device. John F. Krema, Chicago, Ill. Filed July 23, 1903.

750,093. Electric Resistance Furnace. Alfred H. Cowles. Cleveland, O. Original application filed Nov. 20, 1902. Divided, and this application filed April 21, 1903.

750,095. Process of Electrically Heating Materials. Alfred H. Cowles, Cleveland, O. Filed Nov. 5, 1902.

750,102. Electric Automobile. Thomas A. Edison, Orange, N. J. Filed Jan. 9, 1903.

750,132. Electromagnet. Illius A. Timmis and Edgar W. Timmis, London, Eng. Filed June 19, 1903.

750,150. Electric Fire Alarm. Joseph A. Barten and Samuel R. Sneeringer, Philadelphia, Pa. Filed April 30, 1903.

750,170. Method of Electric Heating. Alfred H. Cowles, Cleveland, O. Filed Nov. 5, 1902.

750,171. Electric Furnace. Alfred H. Cowles, Cleveland, O. Filed Nov. 20, 1902.

750,179. Electric Blanket. Charles Foglesong, St. Paul, Minn. Filed Sept. 14, 1903.

750,180. Method of Controlling Spark Production. Lee De Forest, New York City. Filed June 17, 1903.

THE TELEPHONE WORLD.

Coming Meeting of Ohio and Indiana Telephone Association.

Arrangements have been made for the annual meeting of the Ohio and Indiana Telephone Association, which will be held at the Grand Hotel, Cincinnati, on February 17, 18 and 19. Two hundred delegates will be in attendance, and many important matters pertaining to the Independent telephone business will be discussed. A number of prominent telephone men from various sections of the United States will be in attendance and will address the convention.

It has been stated that a telephone company has been organized at Front Royal, Va., and will construct lines throughout Rappahannock County, and connect with those in Page and the adjacent counties in the upper part of Virginia Valley. It is expected that eventually 'phone communication will be had with Washington, D. C., and other points. The projectors of the new line are Messrs. C. W. Trevary, G. W. Forsythe, S. G. Allen and Oder Harrell.

The Collinwood Rural Telephone Exchange Company was organized in Dassel, Minn., a short time ago, with Simon Aster as president, A. J. Broberg, vice-president, and John Enquist, secretary. The company will build about 15 miles of telephone line in the rural districts.

The Gainesboro Telephone Company, of Carrollton, Ga., recently came into control of the lines of the Commercial Telephone Company of Atlanta. The two systems will be united. With this purchase the Gainesboro Company owns about 400 miles of wire and has 10 city exchanges and 60 stations. It is in a very prosperous condition and will largely increase its system.

A new telephone company, with a capital stock of $25,000, and called the Neighbor State Telephone Company, was lately incorporated at St. Paul., Minn. The incorporators are P. M. Andersgood, Sam Gilbertson, H. H. Harvey, Lars Berhardson and Gilbert N. Roen.

The Willow Creek Telephone Company has completed its new line from Madelia to Vernon Center, Minn. The latter place has connections with all the surrounding villages and farming communities, besides a direct line to Mankato and the long-distance 'phone.

At the annual meeting of the Co-operative Telephone Company of Detroit, Mich., C. M. Burton, Max J. L. Towler, J. C. Danzinger, J. W. Howland and A. A. Cowles were elected directors.

A new telephone line, to connect Dundee, Rock Stream, Reading Center and Watkins, N. Y., is being subscribed for along the line. H. J. Hunt, of Reading Center, has the matter in charge.

William Knottes, who owns the telephone system now in use at Long Pine, Neb., has decided to install the Clark automatic exchange system.

The Vermilion County, Ill., Telephone Company has increased its capital from $150,000 to $400,000.

Independent Telephone Competition.

The Fall River, Mass., Automatic Telephone Company is paying its fourth regular quarterly dividend of 1¼ per cent.

The company on December 31, 1903, had 1,160 stations, an increase of 100 for the quarter.

A director says: "The company continues its regular dividend payment in the face of the fact that its toll between Fall River and New Bedford is 15 cents, while the New England Telephone & Telegraph Company has reduced its toll between these two cities from 15 to 5 cents."

For several years past G. T. Conine, a business man, of Prattsburg, N. Y., has been putting up telephone lines from there to various surrounding towns. The enterprise has been gradually extended until there have been erected 150 miles of line, extending to various points in Steuben, Yates and Ontario Counties. In order to more thoroughly and systematically supervise and prosecute the growing business, a stock company has been organized and incorporated with a capital of $10,000. Dr. B. J. Scott is president of the company and R. T. Conine, secretary and general manager. The name under which it is incorporated is the Prattsburg Overland Telephone Company. Already active preparations are being made to double the present territory, which will thus give subscribers a more extended and satisfactory service. Lines will soon be put up connecting Hammondsport, Bath, Avoca, Cohocton, Atlanta, Wayland and many smaller place, with a central office and switchboard at convenient points. The company now has scores of subscribers among farmers and others between the various villages reached by its lines.

The new barbed wire telephone system radiating from Chester, east of Spokane, Wash., has been opened. The new telephone system is independent of the Pacific States Telephone Company, but connects with it at Chester. The farmers have an exchange of their own at Chester, from which the lines to different farmers radiate. There are already 11 subscribers, with 16 miles of line in operation, the longest of which is eight miles.

For some months past the matter of placing a portion of the wires of the Mexican Telephone Company in the city of Mexico has been under discussion. The plans are now pretty well completed and within a short time active work of laying conduits will begin. It is not known yet what arrangements for financing these improvements will be made, although it is the understanding that the Government will foot a portion of the bills. The net result will be to benefit the company through increasing the number of subscribers, and possibly by increasing the rate of tariff.

Contracts were recently made by the board of public safety of Indianapolis, Ind., for telephone service for the police department. The new company will furnish 74 telephones and a new switchboard at the headquarters for $1,250, and the old company will give 84 instruments for $1,248.

New Police 'Phone System.

The police street telephone system, which has been in course of construction in this city for several months, has now been practically completed in five downtown precincts and is in working order. The station houses where the system is now being used are Old Slip, Oak street, Church street, Elizabeth street and Leonard street. Work on the system will be continued until every precinct in Manhattan is similarly equipped.

The system consists of street boxes placed at convenient points throughout each precinct connected with the station house by extra wires put up by the telephone company. Each box is so contrived that when it is unlocked and the door opened the receiver is lifted automatically and connection is established at once with the station house, causing a disk to fall on the switchboard at the sergeant's desk, indicating the number of the box that is calling. The box can be opened and closed after communication with the station house in one minute.

The farmers who live at East Penfield, a hamlet 2½ miles northeast of Fairport, N. Y., held a recent meeting and organized a telephone company to operate in the town of Penfield. They elected their officers and signed incorporation papers. They also signed an agreement with the Interocean Telephone Company, to connect their lines with the Fairport exchange. All their circuits connect directly with Fairport. There will be free exchange between the two companies. Other rural companies are organizing and it looks as though the whole country around Fairport would soon be connected by telephone.

The articles of incorporation of the Hudson, Ia., Mutual Telephone Company were filed with the county recorder a short time ago. The company has no capital stock, doing business on the mutual plan wholly. The officers of the company are: President, H. B. Eighmey; vice-president, William Crownover; secretary and treasurer, W. J. Glenn.

At the annual meeting of the Utica, N. Y., Home Telephone Company the following officers were elected: President, Edgar B. Odell; vice-president, H. F. Miller; treasurer, Edward Bushinger; secretary and manager, C. H. Poole.

At the meeting of the stockholders of the Chicago Telephone Company last week the authorized capital stock was increased to $20,000,000 from $15,000,000. The new $5,000,000 will be spread over possibly three years. In 1899 the company's capital was $5,000,000.

The Livingston County Mutual Telephone Company, of Howell, Mich., has elected the following officers: Frank Backus, president; H. E. Reed, secretary; A. J. Van Patten, treasurer.

A new telephone company has been organized in Daleville, Ind., capitalized at $10,000. The construction will begin immediately. About 20 miles of new pole lines will be built.

The Brunswick Independent Telephone Company, of Medina County, O., has recently been incorporated.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Aurora, Ind.—The city council has refused to renew the electric light contract and the city is in darkness. Plans are under way to install an electric light plant to be owned by the city.

Austin, Tex.—The city water and light commission contemplates increasing the equipment of the light and power plant by the purchase of a turbine engine. The proposed improvements will cost about $20,000.

Baltimore, Md.—New York lighting interests, headed by Anthony N. Brady, were last week given representation in the directory of the United Electric Light & Power Company. This is the company back of the scheme for utilizing the rapids of the Susquehanna River in the vicinity of Conewango for electrical development.

Bancroft, Mich.—The citizens are agitating the question of installing a system of waterworks and an electric light plant.

Boyd, Wis.—The Cirkel Manufacturing Company will install a new electric light plant in this city.

Bromley, Ky.—The citizens here are agitating the question of establishing a system of electric lights and waterworks.

Buffalo. N. Y.—At a recent meeting of the South Park District Taxpayers' Association, a resolution asking the aldermen to substitute electricity for gas now in use in that section was adopted.

Chatham, N. Y.—The Boston & Albany Railroad Company is considering the advisability of installing a private electric light plant in the union station here.

Clinton, Ill.—E. F. Clark is asking a 20-year franchise from Kenney to operate an electric light plant.

Conyers, Ga.—M. L. Wood and W. U. Wallace, aldermen of this city, are investigating the matter of installing an electric light plant here.

Duquoin, Ill.—J. Ward Blakeslee and Ray S. Linzee are desirous of operating the electric light and power plant here and will ask the city council for a franchise to use the streets and alleys. They will also construct a street railway.

East St. Louis, Ill.—A petition has been presented to the council for additional arc lights at various corners of the town.

Eldorado, Ark.—The Eldorado Industrial Company has been formed to produce and distribute electricity for light, heat and power. The capital stock is $80,000.

Fairfax, Vt.—The Vermont Power & Manufacturing Company will install a new electric light plant here.

Ft. Wayne, Ind.—Messrs. Schnitker and Clark, trustees of the town of New Haven, are working for an electric lighting plant for their corporation both for street and commercial lighting.

Gallup, N. M.—The Gallup Electric Light Company has been incorporated with a capital of $50,000, by M. Gunsel and Herbert F. Raynalds, of Albuquerque and Kenneth K. Scott, of this city.

Grove City, Pa.—Applications have been made to the borough council for a franchise for an electric light and power plant.

Heflin, Ala.—The city council has granted to F. F. Taylor and W. B. Merrill a franchise to construct and maintain systems of waterworks and electric lights in this town for a period of 30 years.

Nazareth, Ky.—This town is preparing to install an electric light plant.

New Castle, Pa.—Dr. E. J. Fithian and John Carruthers have applied for a franchise for an electric light and power plant.

Perham, Minn.—The waterworks pumping station and electric light power house were damaged by a recent fire.

Portage, Wis.—It is stated that the Chicago, Milwaukee & St. Paul Road will put in an electric light plant and pumping station of its own in this city

Rapid River, Mich.—The installation of an electric lighting plant is talked of by the business men here.

Shell Lake, Wis.—It was lately voted to borrow $10,000 from the State to establish and equip an electric light plant.

Shelton, Wash.—The local electric light plant has been purchased by W. H. Kneeland, who will enlarge the same.

Teneriffe, Canary Islands.—The electric light company here is desirous of purchasing an American electric light engine of at least 500 hp. Address Senor Don Nicolas Marti, presidente Compania Electricia Industrail, Teneriffe, Canary Islands.

Tybee, Ga.—The Savannah Electric Company is considering the matter of furnishing electric lights here.

Wilmette, Ill.—The North Shore Electric Light Company has secured a franchise from the town board and will install electric lights in this village.

Williamsburg, O.—Charles Hoffman, village clerk, will receive bids for a $12,000 electric light plant.

STREET RAILWAYS.

Ada, Mich.—A committee of the leading business men of this place has been appointed to discuss the route of the proposed Grand Rapids & Ionia Electric Railway. It is believed that the village offers advantages to the road which can readily be shown.

Albuquerque, N. M.—The final step in the transfer of the Albuquerque Street Railway Company to the Albuquerque Traction Company has taken place, which eventually means the old horse car line will be changed to electric. Engineers are completing their plans and surveys for the company.

Charleroi, Pa.—The promoters of the Allenport & Roscoe Electric Railway are making preparations to begin work on the construction of their line in the spring.

Charlottesville, Va.—The Virginia Railroad & Improvement Company will run a trolley from here to Point of Rocks, Md.

Crookston, Minn.—An electric line for the northern portion of this State, connecting Grand Forks, Fargo and Moorhead with this city and Maple Lake, has been proposed here. J. P. Booher is interested in the enterprise.

Galveston, Tex.—Conversion of the Gulf & Interstate Railroad into an electric line, and the consolidation of two other electric lines, all under one control, is reported to have been practically accomplished by John W. Gates and his associates.

Greenville, Ill.—The Southern Electric Company will build several new lines in this vicinity.

Lansing, Mich.—Manager Elliott, of the Lansing, St. Johns & St. Louis Interurban Railway Company, states that he expects to have the road fully equipped with electricity by February 15.

Lynden, Wash.—The immediate construction of an electric line of railways from Bellingham to this city, 16 miles distant, was lately assured, by the filing of a mortgage by the Lynden Electric Company, which was incorporated for this purpose to the Corporation Trust Company of New York for $160,000. C. T. Likins, of Bellingham, is president of the new company; C. A. Wyatt and G. A. Butters constitute the board of directors.

Newburgh, N. Y.—Permission has been granted by the State Railway Commission to the Intervale Traction Company of New York and Newburgh to build a trolley line between this city and Goshen. This line will be about 25 miles in length and will link the Orange County Traction Company and the Newburgh & Middletown Railway Company. The entire system when completed will include about 55 miles of track.

Savannah, Mo.—C. E. Bartlett, D. Eversole and Judge Thompson, directors of the Maryville & St. Joseph Electric Railway, recently met the citizens of Savannah and farmers of the county in a right-of-way meeting. Those present promised assistance in securing right-of-way. The directors announced that they had secured about 12 miles of right-of-way in this county for the line.

Washington, D. C.—The Washington & Marlboro Electric Railway Company may build a line here.

Woodland, Cal.—N. A. Hawkins has been granted a franchise to operate electric railways here for a period of 50 years.

POWER PLANTS.

Boise, Idaho —Neo Bunch is the promoter of a project to put in an electric plant to supply the mines of the surrounding country with power.

Idaho Falls, Idaho.—The Idaho Power & Transportation Company, of which George Chapin is president, will install a 3,000 hp. plant on the Snake River. A dam will be built.

Pasco, Wash.—Considerable interest is being aroused here in the matter of utilizing the falls in the Snake River, either at Fishhook Rapids or Five Mile Rapids, to generate power for irrigation and lighting.

Vera Cruz, Mex.—Filberto Romero, of this city, has been granted a concession by the Mexican Government for the construction of a hydraulic power plant on the river Tanocco at a place called Chorro Grande, in the State of Vera Cruz. The plant will be utilized for the purpose of generating energy for electric lighting and power purposes in the vicinity.

Worcester, Mass.—Theodore C. Bates, 29 Harvard street, wants data regarding the practicability of a long distance electric power transmission.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12½@12⅝c.; Lake 12⅝@12¾c.; casting, 12⅜@12½c.

The Hudson River Telephone Company has declared the customary 1½ per cent. quarterly dividend.

The annual meeting of the stockholders of the Brooklyn Rapid Transit Company will be held on January 29.

The American Telephone & Telegraph Company owns $6,-760,000 of the capital stock of the Chicago Telephone Company.

A foreclosure decree has been entered against the Lehigh Power Company of Easton, Pa., on its mortgage bonds amounting to $325,491. A sale has been ordered.

Supreme Court Justice Kellogg has granted an order appointing Walter P. Butler as referee to sell the Ballston (N.Y.) Terminal Railroad, a local electric line, on March 8.

The disputes arising out of the different interpretations of the leases existing between the Chicago Union Traction Company and its underlying companies are to be investigated by a Master in Chancery.

George R. Beach of Jersey City, receiver for the Storey Motor and Electric Company of Harrison, N. J., announced Saturday last that he was ready to pay to his creditors a first dividend of 25 per cent.

The Brooklyn Rapid Transit Company is said to be negotiating with bankers to float between $5,000,000 and $6,000,000 of bonds. The proceeds will be used to liquidate a debt of about $1,500,000 and to pay for a new power plant.

A director of the Electric Storage Battery Company says: "The company has all the work it can do. There is nothing to prevent our paying dividends as in the past. The Edison battery has not yet proved itself a factor in the market."

The best grades of lake and electrolytic copper are obtainable in New York at 12⅝ cents per pound, as against 13 cents ten days ago. The offering price was reduced ¼ cent on Saturday. The unexpected falling off in the demand from abroad was the cause of the reduction.

Gross earnings of the Toledo (O.) Railways and Light Company for the year were $1,655,000, a gain of $195,909. Estimating the net earnings at $793,000, and fixed charges, interest and rentals at $495,000, there is left available for dividends $298,000. This would be equivalent to about 2⅜ per cent. on the stock.

On April 1 the Manhattan Elevated Railroad Company of New York will turn over to the Interborough Company $1,500,000, its year's net earnings above the 7 per cent. guarantee of the Interborough Company. Present earnings of the Manhattan Company are said to be $5,000 per day ahead of last year.

The annual report of the General Electric Company, for the fiscal year ending January 31, will be submitted early in February. Preliminary information from a director is to the effect that the earnings (January partly estimated) will approximate $7,000,000 in excess of all expenses, fixed charges and dividends. The cash surplus will total about $4,000,000.

There will be a meeting of the stockholders of the People's Rapid Transit Company of Cincinnati on February 12, at which time the present charter will be given up and a new company will be organized under the name of the Cincinnati, Toledo & Detroit Short Line Railway Company, with a capital stock of $6,000,000. The capitalization of the present company is $500,000.

ELECTRICITY.

VOL. XXVI. NEW YORK, FEBRUARY 3, 1904. NO. 5.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - **136 Liberty St., New York.**
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

London's New Tube Railway.

On another page of this issue we are able to give particulars of the new electric railway which, after many delays, has at last been completed for traffic between the heart of the city of London and one of its most populous suburbs, Finsbury Park, some three to four miles to the north. The opening of this line comes at a moment when the three tube lines already working have not recovered from the effect of the Paris Metropolitan Railway disaster. During the past six months or so, we are informed, the passengers carried by these lines have been reduced in number to an almost alarming extent, and a falling off in receipts at the rate of over $2,500 per week in two cases cannot fail to affect the dividend declarations which are made during the next few weeks.

The Great Northern & City engineers and directors are able to commence operations with an undertaking which is in a position to take advantage of the mistakes and troubles which have arisen in connection with earlier lines. It is but natural, therefore, that every precaution for the safety of the public should have been taken. The experience of this latest system should prove interesting.

Aluminum Coming Into Favor.

A five-line item in the Boston *News Bureau* a few days ago, stating that the Edison Electric Illuminating Company had purchased a total of 300,000 pounds of aluminum for its transmission lines, connecting its various suburban companies with its new $4,000,000 Boston power house, or sufficient to equip 250 miles of transmission line, has aroused considerable interest as to the extent that aluminum is taking the place of copper in electrical transmission.

The Edison people took exception to the statement on the ground that it would appear to show that that company had abandoned copper for aluminum, while as a matter of fact their purchases of copper have been far greater than of aluminum.

The facts in the case are that the Edison Company has purchased, to be exact, a total of 298,245 pounds of aluminum wire, which represent a total of 246 miles, sufficient to equip 82 miles of transmission line, a high tension transmission system requiring three sets of wire. This fact shows that aluminum is coming into favor.

Aluminum is in quite extensive use in New England for electrical transmission. The Massachusetts Electric Companies has purchased about 500,000 pounds as a substitute for copper wire and it is giving complete satisfaction, being much lighter on the poles than copper and easier to handle. The Boston & Maine Railroad, the Tucker, Anthony & Co. properties, Hartford Electric Light Company and the new Milford (Conn.) Power Company have all placed large orders for aluminum wire as a substitute for copper.

The Lewiston & Auburn (Me.) Electric Light Company which has equipped its lines with aluminum, writes the following letter:

"Last year we put out about 20 miles of aluminum wire equipment and I think we shall use it in the future for all our trunk lines. We like it on account of its weight, also because we believe the chances of breakage are much less with aluminum that with copper and we also find that it does not load up with snow and ice as our copper feeders do."

One transmission line of the Niagara Falls Power Company, from Niagara Falls to Buffalo, 26 miles, is aluminum, over which is transmitted current at a voltage equivalent to as high as 17,000 hp., and

since its installation a few years ago it has not shown the slightest deterioration from atmospheric conditions.

* * *

The More Economical Production of Electricity.

Those who are responsible for the business side of a public electric light and power plant are constantly having brought before them the very practical question, "At what price can you supply power to factories and workshops, in competition with isolated steam power plants?" There is plenty of evidence at our disposal to show that each is superior to the other, and this evidence receives its coloring from the particular experience or leanings of the engineer or official who produces it. Local considerations, and especially the contiguity or otherwise of the factory to be driven, to the source of fuel, affect the result very largely. The position of the whole question of electric driving has been changing considerably during the last few years. It is not now so necessary as it was to enter into elaborate arguments to convince the works proprietor or his manager of the advantages which are sure to follow the abandonment of antiquated steam driving. The day for this may perhaps be said to have gone by, at any rate that is so for the generality of cases. The eloquent object lessons open to the eyes of manufacturers on every hand do for the electrical engineer this educational part of the work, which, in England at least, proved to be one of the hardest problems of all not so very long since. The present position of the matter, then, is not to convince the inquirer that he can save so much per cent. of his working expenses, but to help him to decide which course is likely to be the more profitable for him to adopt, whether he shall put down his own generating plant, or take supply from the public mains.

In the Lancashire weaving and spinning mills districts fuel is within comparatively easy reach of the numerous manufacturing towns, and it may be said that in order to study the question of fuel economy, no better example could be taken than the coal consumption at these works. They can produce an indicated horse power hour for about 2 pounds of good coal, and at $1.75 per ton they show an ideal figure of .25 cent per unit for coal consumption. The conditions which obtain in mills of this class conduce to a very high load factor—practically 33 per cent.—and the losses from condensation in steam pipes are a minimum, whilst the power taken by the auxiliary machinery, feed pumps, etc., is a very small percentage of the output, notwithstanding that there is a poor vacuum at certain times of the year, comparatively low pressure, and the mills work without any superheat, except in isolated instances. The load factor is therefore responsible entirely for the fuel economy. If they had the same load factor many generating stations could obtain the same fuel economy, and those which are suitably situated for coal and water could show still better results; but the fact remains that no English generating station has such a load factor, and Mr. A. S. Giles, who is responsible for the operation of the Blackburn lighting and traction power station, suggested at a meeting of the Manchester Institution of Electrical Engineers on January 19 that electricity works' engineers should study their generating costs most carefully item by item. The coal bill represents some 50 per cent. of the total works' costs and is therefore the most important factor of all. There is no portion of a steam plant perfect indeed, each is the seat of losses, more or less serious. The points taken by Mr. Giles in the course of his recital of these losses were: The engineer must make his own tests of the calorific value and cleanliness of the fuel that he adopts before he places his contracts; for large stations mechanical stokers are found to be most satisfactory and to lead to big economies, but for small stations burning, say 50 tons per week, they show but little gain over hand firing unless it is necessary to avoid all smoke, or to burn a very small low class fuel.

The conditions of combustion, the admission of air, and the analysis of flue gases are not studied sufficiently in central station practice. The cleanliness of the surfaces of the metal between the furnace gases and the water, affects the efficiency from 10 to 15 per cent. or even more; to get the maximum efficiency from the fuel there must be the least possible loss of heat in transmission from the fuel to the water. The loss of heat by radiation is a serious item, and engineers are concerning themselves more and more with the use of the most effective composition for covering boilers, pipes, etc. The economic advantages of superheat with regard to coal consumption are most marked, and Mr. Giles gave tabulated data showing what could be gained in this direction when compared with the use of saturated steam. Some central stations do not obtain a good vacuum at the engines, and separate condensing plants are to blame for some of the poor results on record. The tables prepared by the author fully proved that an enormous loss of heat takes place in central stations in converting the heat from the coal to electric energy. Increasing the load factor and reducing the coal bill were the chief directions in which the engineer could look for help toward supplying power at cheaper rates in order to compete with the isolated plant.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Secretary Davis informs us that at a meeting of the executive committee of the National Electric Light Association, held at the Waldorf in this city January 25, the dates for the next convention, to be held in Boston, were decided upon, namely, May 24, 25 and 26.

President Mellen of the New Haven Railroad has issued orders to equip a vestibuled train with an electric lighting plant, with generators on the car axles. It is his intention to replace gas with electricity all over the line.

A cable dispatch from Paris says the *Matin* and other leading papers are loud in demanding that radium remain a specific French article, which all the world shall buy in France. "Radium," says the papers, "is a French discovery, and we would be foolish to allow other nations to profit by the genius of our scientific men." At the same time Austria is being savagely attacked "for keeping up the price of the raw material"—in order to protect her Bohemian glass industry. The only place outside of Austria where pitchblende, the raw material for radium, is obtainable at present is in Buffalo, N. Y.

Richard T. Laffin, who will be general manager of the big American street railway system to be inaugurated in Manila, states that his company will invest $4,000,000 in organizing a street car service of 40 miles.

The question of the exportation of electricity from Canada to the United States has reached a point where it must be decided one way or the other. A deputation headed by Mr. W. Caryl Ely, of the International Railway Company of Niagara Falls, N. Y., last week interviewed Premier Ross on the situation. Mr. Ely has made application for permission to bring electric power from his company's power house on the Canadian side of the river to operate its cars at Niagara Falls. The Ontario Government doubts its right to permit such exportation but will give the matter due consideration.

ELECTRIC TRAINS ON THE NORTH-EASTERN RAILWAY IN ENGLAND.

BY FRANK C. PERKINS.

The electrification of the North-Eastern Railway in England has created a great deal of interest, not only in Europe but also in America, for it is well known that the same problem will have to be faced by managers of every railway operating near large cities and having a considerable amount of suburban traffic. The only method of competing with the numerous trolley lines for suburban traffic is to change the method of operation from steam to electric power. This is the only means by which the present steam railways can increase or even maintain the profits derived for suburban traffic.

The accompanying illustration, Fig. 1, shows one of the new trains on the North-Eastern Railway operated upon the direct current third-rail system from the city of Newcastle-on-Tyne through the various towns and cities in that neighborhood and along the River Tyne, both banks of which are densely populated, and built up with many engineering works and ship building yards. The North-Eastern Railway also has an extensive holiday resort passenger traffic, as on the north of the mouth of the River Tyne lie Tynemouth and Whitley Bay, which are also favorite residential districts. In addition to the electrical trains for passenger service of the character shown in Fig. 1, electric locomotives are employed in the Quayside Branch Line, which is used for freight traffic only. The object of operating this line electrically, carrying as it does only freight, was to overcome the ventilation difficulties which now prevent the line from being fully utilized owing to its being on a very heavy gradient and almost entirely in tunnel. The current for operating the electric trains is at present obtained from the Neptune Bank Station at Wallsend, owned by the Newcastle-on-Tyne Electric Supply Company, Ltd., but as this station is now running at nearly its full capacity, in the near future power will be taken from the new Carville steam turbine station now under construction about 1,000 yards further down the river. The new Carville power station now building will be equipped with a number of steam turbo-generators of 5,000 kw. maximum capacity. The turbines are being constructed by C. A. Parsons & Co., and are to be supplied with steam at 200 lbs. pressure, superheated by 150 degrees Fah. The condensers are installed underneath the steam turbines so as to secure the highest vacuum. On account of the small space required for the steam turbines as compared to high power reciprocating engines, it was not considered necessary to place the boiler house parallel with the engine room and instead a separate range of boilers running at right angles to the engine room is provided for each turbine, one centrally fired boiler house is really arranged for every two ranges of boilers, the same being provided with condensers, induced draught fans, independent flues and a short iron chimney. The boiler equipment is of the Babcock & Wilcox type and the above-mentioned arrangement provides a very short and simple steam pipe system, which it is possible to increase in capacity at any time without affecting the general plan of the station, or interfering in any way with that part of the plant already in operation, as the station can be easily extended in any direction.

The steam turbines are directly coupled to alternators of the rotating field type with direct connected exciters. The three-phase alternating current produced by the 5,000 kw. generators has a frequency of 40 cycles per second and a pressure of 5,000 volts. This current is conducted over three-phase high tension cables supplied by Siemens Bros. & Co. to five substations located at Benton, Kenton, Wallsend, Pandon Dane and Cullercoats. The current is reduced in pressure at the substations by static transformers of the Westinghouse single-phase, oil-insulated, self-cooling type and changed to a direct current of 600 volts pressure by 800 kw. rotary converters installed in the various sub-stations. There are fourteen of these rotary converters in all having a total capacity of about 12,000 kw., one of the largest sub-stations, that at Pandon Dane, having four rotary converters of a capacity of 3,200 kw. In order to take care of very heavy loads these rotaries were constructed to stand an overload of 200 per cent. for a short length of time and an overload of 100 per cent. for nearly a quarter of an hour without injury. The trains on the North-Eastern Railway operated by electric power consist of three cars, a trailer being placed between two motor cars. The motor cars are arranged with operators' compartments at one end only, although a master controller is arranged at the other end as well as in the trailer cars so that the trains may be controlled from any point where there is likely to be need of such control. It is impossible to leave a master controller in a wrong position or to work two of them at the same time on account of the interlocking handles which are provided. The multiple unit system was considered the best for this purpose as all of the electrical lines enter the terminal central station at Newcastle and the trains have to be taken in by one locomotive and out over the same lines by another, causing great difficulty in working the suburban traffic. The electrification of these lines and the adoption of the multiple unit system was considered a correct solution of the problem.

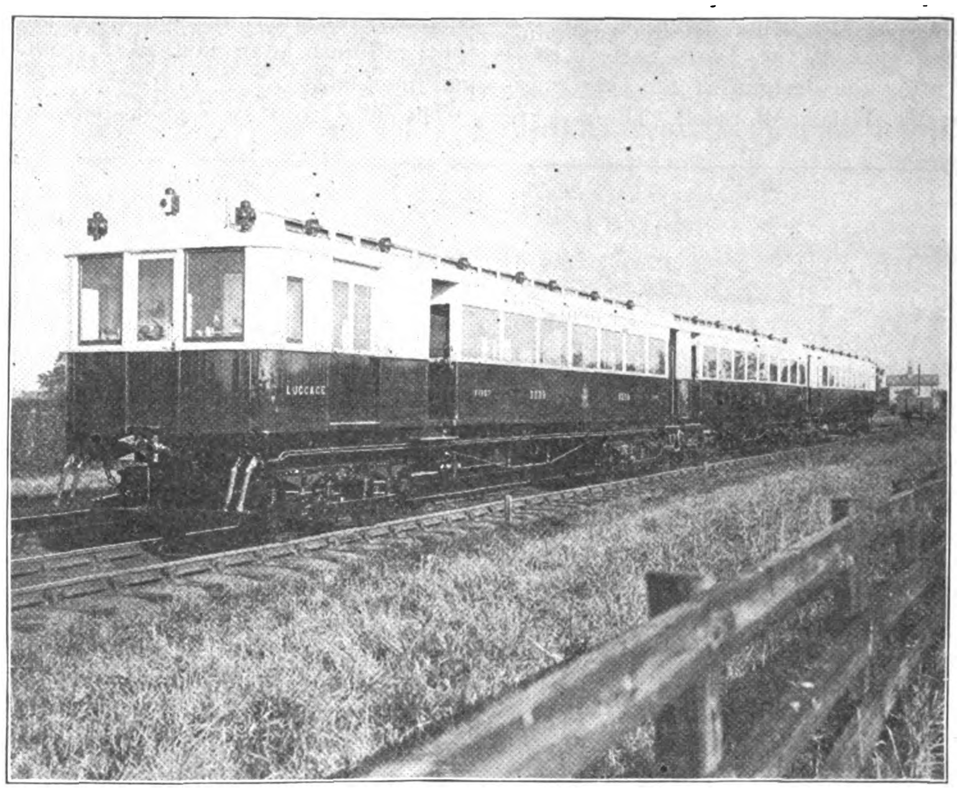

Fig. 1.—Electrically Operated Trains on the North-Eastern Railway.

A number of electrically operated switches are located between each motor car for properly connecting the motor winding and for varying the resistances step by step as desired. These switches are controlled by current conducted through a nine-wire multiple cable which runs from one end of each motor coach or trailer to the other with coupling devices at each end. By this arrangement, there is a continuous nine-wire cable from one end of the train to the other, and by operating any master controller the corresponding electrically operated switches on all of the motor cars are moved at the same time.

The cars are being equipped at the York Works of the North-Eastern Railway after the designs of the chief engineer, Mr. Wilson Worsdell. The cars are each operated by two General Electric 66 motors having a total capacity of 300 hp. Both of these motors are carried on one four-wheel bogie truck and each motor car is carried by two of these trucks, constructed after the designs of the chief mechanical engineer, Wordsell, by the Brush Electrical Engineering Company. The electrical train shown in Fig. 1 is heated and lighted by electricity and on a recent test easily attained a speed of 45 miles per hour. The average speed including stops is about 22 miles per hour for an accommodation train, the total time required for the trip between Tynemouth and Newcastle, a distance of about 8 miles, being 23 minutes. The high speed through passenger trains make the trip without stops in about 15 minutes. The electric locomotives operating on the North-Eastern Railway Quayside Branch Freight Line are capable of hauling a train of 300,000 lbs. up grade at a speed of 9 to 10 miles an hour, and of starting such a load up a gradient of 1 in 27 when necessary. These locomotives are equipped with multiple unit controllers and Westinghouse air brakes, the same as the motor cars. Each motor car is provided with four contact shoes for collecting the necessary current from the third rail. One of these contact shoes is arranged on each side of each bogie truck, and all of the contact shoes on the train are connected together. This obviates the possibility of the train losing its supply of current, even where the continuity of the third rail must be broken, as at crossings and junctions.

The third rail is of Vignoles section and is made of high conductivity steel weighing 80 lbs. per yard. The third rail is mounted on insulators placed about 4 feet from the center of the track, outside of the running rail. The third rail is not protected except at stations where two creosoted boards are bolted against distance pieces on each side of the rails, the same arrangement also being used at level crossings. The current is returned at present through the track, but the third rail has been so placed that a special return rail can be installed between the running rails at any time in the future should this be found desirable. It was found necessary to replace the standard fish-plates by new ones of special design in order to allow sufficient space between them and the web of the rails to admit of the use of protected bonds. The accompanying illustration, Fig. 2, shows the foundations of the Carville power station, including those for the steam turbines and generators as well as the boiler equipment. The electrical equipment of the sub-stations is being constructed by the British Westinghouse Electric & Manufacturing Company, Ltd., while the electrical equipment of the rolling stock and the permanent way is being supplied by the British Thomson-Houston Company, Ltd.

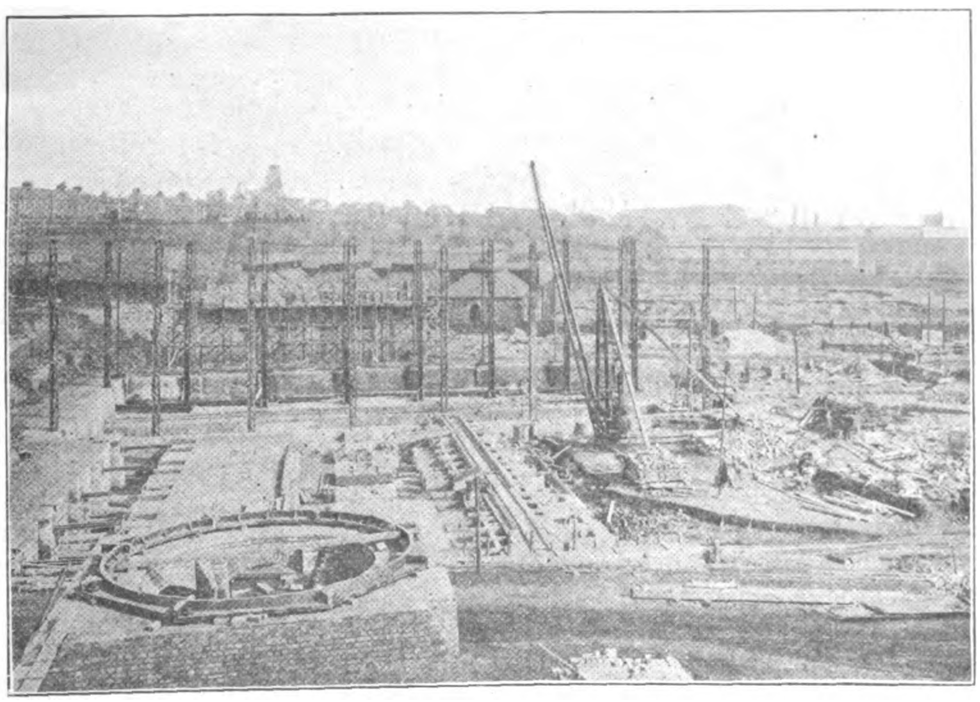

Fig. 2.—Steam Turbine and Generator Foundations of Plant for Furnishing Power to Trains of North-Eastern Railway.

INCANDESCENT LAMPS IN GENERAL, THEIR SMASHING POINT IN PARTICULAR.*

BY GEORGE C. KEECH.

It is my desire to present to you today a paper on incandescent lamps which will clearly describe the results of considerable effort along new lines long desired, but never before accomplished.

Carl Hering, 10 years ago, coined the phrase "Smashing Point," which has been part of the electrical nomenclature since that date. This expression had the excuse which gives all slang a place in our language. It filled a want.

The leading minds in the industry had long appreciated that incandescent lamps were kept upon circuits long after they had outlived their usefulness.

This half descriptive phrase invited explanation and discussion. In an incredibly short time the idea that 80 per cent. of the initial candle power of a lamp was the limit of its useful life was universally adopted.

From the very birth of this expression came the thought that the next step toward the ideal lamp was to make a lamp which would automatically die when it had lived out its usefulness.

We have recently said "If incompetent employes would discharge themselves automatically, business would be easier." I intended to draw a homely comparison between an incandescent lamp and a horse, from an experience of a few summers ago in Michigan.

A central station friend of mine asked me to drive over and help him test out some lamps which he was removing from his lines with the idea of culling out the dim ones. I noticed in the yard near the barn a very lame horse. I questioned the man, and he stated that about five years before this horse had broken its leg, and although it was unfit for work, he had kept it and fed it just because it was a good horse once.

In testing out my friend's lamps, he

* Paper read at the twelfth annual convention of the Northwestern Electrical Association held at Milwaukee, Wis., Jan. 20-22, 1904.

brought forth a peculiar looking specimen and said he had taken it from a minister's study table, much against the latter's wishes. He said: "Don't take that lamp away, it is the best one I have in the house, an old standby, I have had for five years." It tested $6\frac{1}{2}$ cp. at 85 watts. Then I thought of the horse, and have never forgotten either.

Now a perfect horse, from the time it was purchased, would do a certain amount of work daily at the same expense for food and attention and continue this indefinitely. A perfect incandescent lamp would likewise burn forever at its initial candle power, and with the same hourly consumption of current.

As neither horse nor lamp is capable of such a performance, and the tendency of both is to decrease gradually in usefulness until finally the cost of maintenance is more than the actual profit to the owner, the next best condition would be for them to continue for the longest possible period at a good average profit and then die.

Until recently this has been held as an ideal performance for a lamp, but it has been the general opinion that there comes a time when the horse should be shot and the lamp smashed.

The trouble is that the user will not carry out this idea, but lets the lamps burn until they are dim, and condemns the company which furnished the current.

Every station is troubled with poor lamps and to obviate this many companies go to the expense of periodical renewals.

Although this expense is apparently heavy, there are cases on record of 8 per cent. dividends being paid by companies who have renewed all the lamps on their lines as many as four times a year, and their customers have always had bright light.

Alexander Dow, of the Detroit Edison Illuminating Company, has stated that 90 per cent, of customers' complaints could be traced to dim lamps.

Dim lamps is one of two things and sometimes both. They disgust the user by their pale yellow glimmer, or increase his bills because he uses more than he ought; either way the reaction is against electric light and the lighting company.

This dissatisfaction arising from poor illumination makes renewals a necessity.

For those who are interested in the proposition of free renewals, I would refer to a paper read at the National Electric Light Association meeting in Cincinnati in 1902, by a central station manager, wherein he stated that since adopting free renewals he had passed beyond the point of complaint of service. Another stated that he had retained a number of dissatisfied customers by giving them a few new lamps to prove that the trouble was there instead of in the system and by doing this he unwittingly converted himself to the free renewal plan.

Although many companies realize the evil consequences of burning dim lamps, many customers object to the annoyance of frequent renewals and the expense to the company is no small item.

Some recent improvements in the manufacture of incandescent lamps had created such extensive comments that it seems necessary to explain before this convention for the first time the reasons and results of these experiments. It has been said that the filament is the heart of the lamp and the vacuum its lungs.

As to the vacuum, it is now produced by a process of chemical exhaustion, which is considered the only perfect one.

It is well, however, to go into some of the details of the development of the filament which will best lead up to the points in question.

The years 1878 to 1880 saw the inception of what approached nearest to the present incandescent lamp, and since that time the composition of the filament itself has claimed a large share of the experimenters' attention. Various materials have been used. The paper filament of Maxim, the cotton thread of Swan, and the bamboo of Edison were all, however, of cellulose, so that cellulose has been the basis of all lamp filaments since the beginning.

The present cotton fiber is mixed with certain ingredients, formed into a pasty mass and squirted under a high pressure through small apertures into threads whose original diameter before carbonizing is about four times greater than when it is ready to put into the lamp.

The exact composition and exact processes are in a great measure secret, but a general idea may be had from these statements.

Speaking of possible improvements along this line, Dr. Louis Bell, in his work, "Art of Illumination," states: "It may be that we must look to the chemist rather than to the electrician for the final word as to illumination. I may add that the combined knowledge of chemistry and electricity has brought about the results which I shall mention shortly."

A thorough knowledge of chemistry and a complete chemical laboratory are requisites of the modern lamp engineer, and while our physicians are experimenting on remedies to produce certain effects on the human system, our lamp engineers are likewise obtaining results on the filament which, as before stated, may be considered the heart of the lamp itself.

It is here in the engineers' laboratory that the regulation of the life of the filament has been worked out and the automatic smashing point assured.

To refer again to the process of developing the filament from the original cellulose thread; after squirting it is shaped and packed in a crucible with powdered graphite and baked until thoroughly carbonized. Considerable effort is required to make this thread of an even diameter for its entire length.

The process of treating or flashing consists in passing a gradually increasing current through the filament in a bath of hydro-carbon vapor. The hot filament decomposes this vapor from which the carbon is deposited upon it. This process is continued until the thread has received a complete coating of hard, pure, graphite carbon which gives it greater mechanical and electrical stability when operated in the lamp and also makes it of the proper diameter and resistance for the voltage and efficiency for which it is intended.

Although the treating is valuable yet a proper foundation is necessary and it is to this foundation that great efforts have been given.

All of the above has been explained to show the possibility of changing the value of lamps by skillfully manipulating the filament in its manufacture.

Now to summarize: Customers should have bright light every hour and every ounce of coal should produce good value in light.

Complaints should be stopped by getting dim lights off the circuits.

A consumer should get an average of 90 per cent. of the lamps initial candle power.

It is agreed that a lamp is useless after it has depreciated 20 per cent. As every one realizes that it is economy to remove a lamp at this point and, as but few practice it, the only really economical lamp to use is one which will burn out at or near its smashing point.

If, then, it were possible to have lamps automatically extinguish themselves, when they had fallen to this point where they were no longer economical, say at 20 per cent. below their initial candle power, one great step toward the final polarization of electric lighting would be accomplished.

Exactness is not possible but lamps are made which will burn out very close to such a point, and the important result is practically obtained.

Such lamps will smash automatically and must be renewed. There is no room

for forgetfulness. A renewal cannot be neglected.

COLLAPSING PRESSURE OF TUBES AND FLUES.

ARTICLE IV.

BY W. H. WAKEMAN.

Fig. 4 illustrates the ends of two flues flanged and riveted together in compliance with the law relating to such flues. The flanges must be not less than 2.5 inches deep and strengthening rings must be inserted between the flanges as shown. These rings may not be less than one-half inch thick and 2.5 inches wide. The joints between this ring and the flanges may be caulked on both inside and outside thus making them perfectly tight. When built in accordance with these specifications the safe working pressure is determined by the following formula:

$$\frac{89{,}600 \times t^2}{L \times d} = P.$$

t = thickness in decimals of an inch.
L = length of section in feet.
d = diameter of flue in inches.
P = safe working pressure.

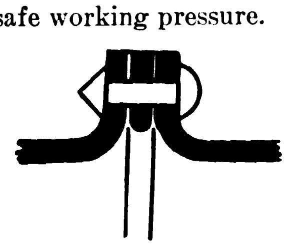

FIG. 4.

Application of this formula to four specimens of flues made in sections 4 feet long gives the following safe working pressures:

14 inch flue	.35 inch thick,	196 pounds.	
16 "	" .37 "	" 191 "	
20 "	" .4 "	" 179 "	
40 "	" .6 "	" 201 "	

This form of construction is known as the Adamson ring, in honor of Mr. Adamson who invented it more than 50 years ago and subjected it to severe tests in proving its value. It has also stood the more valuable test of long use in practical service.

Fig. 5 illustrates another plan for fastening sections together, which adds much to the strength of a plain flue. It represents the ends of two sections about one-half inch apart, covered by a ring made of tee iron substantially riveted to both sections.

Fig 6 shows another form of joint made by riveting a ring of steel, that is hoop-shaped, to both sections. This also adds to the strength of a plain flue, and it admits of expansion and contraction to a limited degree, caused by heating and cooling the boiler.

Fig. 7 is a section of a flue strengthened by a ring made of angle iron, which must be made and applied according to the following specifications: The angle iron may not be less than 2.5 inches deep and it must be at least twice as thick as the material composing the flue. It must be

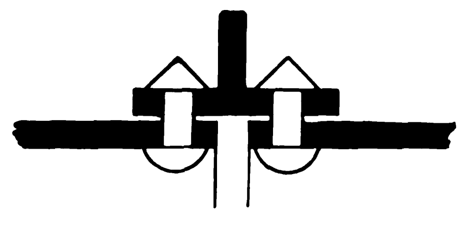

FIG. 5.

substantially riveted in position with wrought iron thimbles between flue and ring. These thimbles are not to be more than 2 inches long, and the rivets passing through them are to have a diameter of at least one and one-half times the thickness of flue. The pitch of these rivets must not exceed 6 inches measured on the outer surface of ring. This ring and flue are illustrated in Fig. 8, in which one-half of each is shown with rivets between them. The thimbles make the bodies of these appear as large as the heads, but this explanation will make the matter plain.

The safe working pressure of flues shown in the four previous illustrations is determined by the last formula given, which was applied to Fig. 4.

To determine the proper diameter of a flue made in sections, when the other conditions are stated, the following formula may be used:

$$\frac{89{,}600 \times t^2}{L \times P} = d.$$

t = thickness in decimals of an inch.
L = length of section in feet.
P = safe working pressure.
d = diameter in inches.

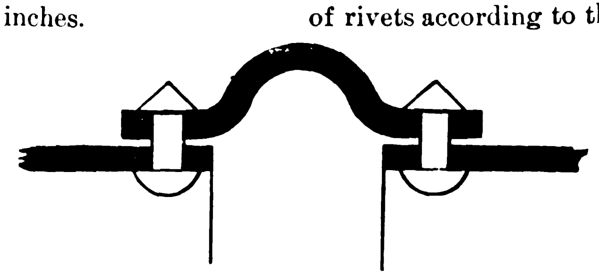

FIG 6.

Applying this to the case of a flue made in sections 4 feet long and .37 inch thick, to carry 191 pounds pressure, gives this result:

$$\frac{89{,}600 \times .37^2}{4 \times 191} = 16 \text{ inches.}$$

To determine the length of sections, when other dimensions are given, this formula applies:

$$\frac{89{,}600 \times t^2}{d \times P} = L.$$

Taking a flue 20 inches in diameter made of iron .4 inch thick, to carry 179 pounds pressure, results as follows:

$$\frac{89{,}600 \times .4^2}{20 \times 179} = 4 \text{ feet long.}$$

Suitable thickness of material for such a flue, when all other data are presented, can be determined by the next formula:

$$\sqrt{\frac{d \times L \times P}{89{,}600}} = t.$$

This shows that a 40 inch flue, made in sections 4 feet long to carry 201 pounds pressure, must be

$$\sqrt{\frac{40 \times 4 \times 201}{89{,}600}} = .6 \text{ inch thick.}$$

There is still another plan for strengthening flues, which consists of a ring made of half round iron and riveted to the flue. This is illustrated in Fig. 9, showing a section of flue and of ring, also a rivet and a thimble between ring and flue. In order to meet the requirements of the U. S. Board of Supervising Inspectors

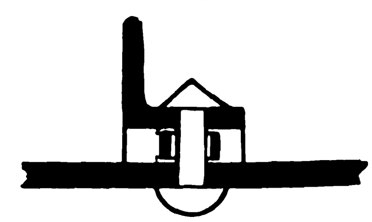

FIG. 7.

the following specifications must be observed:

The area of cross section of half round ring must equal 9.6 times the thickness of material in the flue, and the thimbles must not be more than 2 inches long at their shorter points. No rivets less than ⅝ inch in diameter shall be used, and the pitch measured on the outer surface of ring shall be based on the diameter of rivets according to the following table:

For ⅝ inch rivets, pitch = 4 inches.
For ¾ " " " " 6 "
For ⅞ " " " " 8 "

The diameter of half round iron to be used for this purpose is to be found by means of using the following formula:

$$\sqrt{\frac{.6 \times t \times 2}{.7854}} \quad d.$$

t = thickness of material composing the flue.

d = diameter of half round iron.

For a 40 inch flue made of iron .6 inch thick the half round iron must be not less than 3.8 inches in diameter.

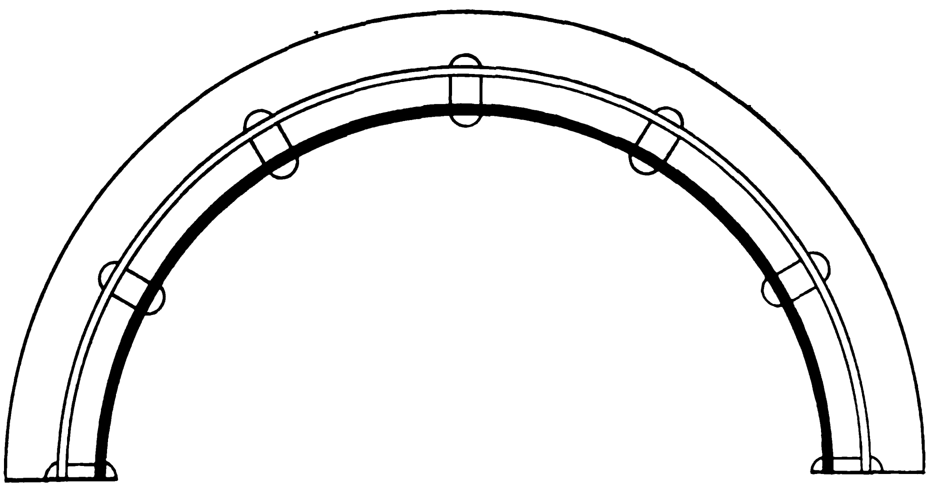

FIG. 8.

Practically the same result may be obtained by multiplying the constant 24.5 by the thickness of the material and extracting the square root of quotient.

The safe working pressure for a flue strengthened by rings made of half round iron is determined by the next formula:

$$\frac{89,600 \times t^2 \times .75}{L \times d.} = P.$$

It will be noted that this contains one more constant than is found in the formula given for determining the safe working pressure of a flue made in sections, and this is the only difference: The result of introducing this constant is to reduce the safe working pressure to three-quarters of that obtained by the above mentioned formula.

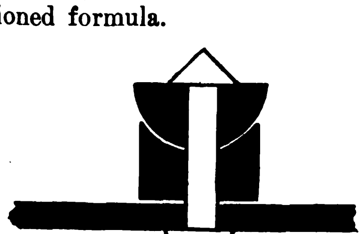

FIG. 9.

The three following formulas are to be used for the purposes stated, in connection with flues strengthened by half round angle iron rings:

Diameter of flue—

$$\frac{89,600 \times t^2 \times .75}{L \times P} = d.$$

Length of sections measured from center to center of rings—

$$\frac{89,600 \times t^2 \times .75}{d \times P} = L.$$

Thickness of material—

$$\sqrt{\frac{d \times L \times P}{89,600 \times .75}} = t$$

This concludes what may properly be called a full review of all important formulas given us for use in relation to boiler tubes and flues.

LONDON'S NEW TUBE RAILWAY—THE GREAT NORTHERN & CITY SYSTEM.

(From our London Correspondent.)

On Wednesday, January 12, a company of London technical and newspaper press representatives went for a trial run on the fourth completed electric railway constructed under the English metropolis on the twin-tunnel principle. The system differs in many respects from the three-tube railways which have been working for the last few years, as the following particulars will show:

Although it is some 14 years since the act for the Great Northern & City Railway was approved by Parliament, it was not until 1899 that it was possible to commence constructional operations, because the nervousness of financial men and public investors prevented the raising of the necessary capital in the earlier years. The work of construction has therefore taken four or five years, and trains are to run for public service early this month.

The line connects the important Great Northern station at Finsbury Park, just at the London four-mile radius, with the heart of the city in an almost straight line. It is calculated that shortly after opening the Great Northern & City will be carrying about 27,000,000 passengers per annum. The Central London is at present conveying 7,000,000 of passengers per mile per annum. The morning and evening traffic will be the chief "loads," and when the traffic eases off in the middle of the day shorter trains will be run, this requirement, more than anything else, having weighed with the directors in adopting the multiple unit system. The line is 3½ miles long, and there will be a three minutes service, the single journey being completed in about 13½ minutes, including four intermediate stops of 20 seconds each. The trains will be worked on the shuttle principle at the termini, thus avoiding shunting round the end of the station.

The tunnels are of unusually large diameter, i. e., 16 feet, as against 11 feet 8 inches on the Central London Railway, and 10 feet 6 inches on the City & South London. The advantages of this are obvious. Despite the larger size of the tunnels, we are told that the capital expended per mile is about the same as that of the Central London. Special attention has been devoted to the safety of the public, and one direction in which this is to be seen is in the great width and ample proportions of the stairs and the passages by which they are approached.

A word may be said as to the method of driving the tunnels, a somewhat more powerful type of shield than has been usually employed in works of this class having been adopted. The modern shield, as at present used, is of the nature of a cheese taster in its method of boring, and slides upon the completed cast-iron tube which is constructed within its thin steel after end, much as the cap of a telescope does upon its body. It is pushed forward by powerful hydraulic rams which press against the last completed ring of the cast-iron tunnel. In order to minimize the amount of noise and vibration, a vitrified blue brick invert has been introduced for a very great proportion of the length. It has been demonstrated during the trial runs that the introduction of this material, combined with a cast-iron roof, will have this effect. It is less resonant than the complete iron rings, and the fact that the tube is constructed of a combination of such different materials is claimed to make the transmission of the waves causing sound more difficult, with a consequent saving in noise.

As to fire-proofing precautions, these have been well taken, even the signalmen's cabins being fire-proof structures, and the platforms are of solid concrete and iron construction.

Now as to the rolling stock, and the power station equipment.

Each train is composed of seven coaches (each 50 feet long), and the width is equal to that of the widest carriages that can be run over any British railway, viz., 9 feet 4 inches. The height is 12 feet 2 inches. As the length of the station platforms is about 450 feet, for the terminal,

and 420 feet for the way stations, ample margin has been allowed for the lengthening of the trains should the growth of traffic necessitate.

Three of the coaches per train are motor-coaches and four are trailers, the seating capacity of the whole being about 430 passengers. Each motor coach has two motors, one upon each truck, rated 125 hp., and built by the General Electric Company of Schenectady. The carriages were built by the Preston Company and the Brush Company, and they have Westinghouse quick-acting brakes. The multiple unit system adopted is the same as on the Central London and on the New York Elevated, and the British Thomson-Houston Company of Rugby designed and carried out this part of the undertaking, and in fact all the rest of the electrical plant.

The cariages are teak structures with steel underframes and are of the corridor type. They have a novelty in the shape of a central door, which will enable unloading to be expeditiously carried out at terminal stations. These doors are so arranged that they cannot be opened from the carriage itself, and therefore there is no danger of a passenger opening them and leaving them open at any way station. They will be opened by special porters at the termini.

The generating station is situated alongside the Regent's Canal, from which its water supply for condensing, etc., is drawn. Coal landed from barges is conveyed to the bunkers and fires entirely by automatic machinery.

The main plant consists of four engines built by Messrs. Musgrave & Co. of Bolton, of 1,250 hp. each, of the slow speed, cross-compound, surface condensing type, and they take steam from ten economic boilers made by Davey Paxman. The flywheels weigh 45 tons, and the engines are capable of sustaining momentary overloads of 100 per cent. The generators are of the British Thomson-Houston traction type, and they generate at 575 volts continuous current for feeding to the conductor rails. For the first time on any London railway two such rails are provided, one being placed on each side of the track, outside. This method has been adopted with a view to greater safety and continuity of working.

The tunnel electric lighting is done from an independent source so that in the event of derailing, breakdowns, etc., the tunnels will not be plunged into darkness. There is also an emergency gas lighting service provided in all the stations. A continuous fire-proof concrete gangway has been made so that passengers may safely make their way to the nearest stations in case of necessity.

Lifts have of course had to be provided at stations. Those at the Moorgate Street and Essex Road stations are Easton's electric lifts, but those at Finsbury Park station are electric-hydraulic, they being so designed and made in view of the small amount of headroom.

For the first three years the railway will be worked by the contractors, Messrs. S. Pearson & Son, Ltd. Mr. R. P. Brousson is the engineer-in-chief under the Great Northern & City Railway Company.

ELECTRICAL STATION PRACTICE.

ARTICLE XXII.

BY W. H. RADCLIFFE.

A common form of the alternating current ammeter is that operated by the heating effect of the current. Such instruments are perfectly independent of magnetic conditions and therefore may be mounted without any precautions being taken, near generators, bus bars, etc. They are also independent of the shape of the alternating current wave and of the frequency of the current.

The operation of a hot wire measuring instrument is governed by the change in length of a special wire in the meter, caused by the heat developed therein by the passage of a current through it. This wire in an alternating ammeter is about 6 inches long and is composed of platinum silver. The connections between the binding posts of the meter and the platinum-silver wire are made by a number of silver strips in parallel. Attached to the platinum-silver wire is a phosphor-bronze wire which runs downward to a terminal at the bottom of the instrument; from the phosphor-bronze wire a strong fiber branches off which is looped around a steel drum carrying the pointer. The end of the loop is fastened to a spring which tends to keep it taut, and the drum around which the loop is made is of steel and is mounted in jewels.

The main portion of a current passing through the meter flows through a shunt of low resistance, but a part of it in traversing the platinum-silver wire heats it and thereby causes it to increase in length; this elongation in the platinum silver wire tends in turn to cause some slack in the phosphor-bronze wire, but the slack is at once taken up by the action of the spring on the fiber. The movement of the fiber causes a rotation of the drum around which it is looped, and as the pointer is attached thereto it is deflected over the scale. The amount of the deflection of the pointer indicates the exact number of amperes of current passing through the meter, because the conditions are such that both the heating and elongation of the wire, and consequently the force tending to rotate the pointer, are directly proportional to the strength of the current. Each of these instruments are usually provided with a permanent magnet mounted just above the steel drum; this magnet tends to dampen the movements of the drum so as to make the instrument dead-beat. The term "dead-beat" is one commonly used in connection with electrical measuring instruments and means that the pointer quickly takes up its position of equilibrium under the action of the current, and that when the current is taken off the pointer comes rapidly to the zero position. In the construction of each instrument a short-circuiting switch is introduced for shunting in full the hot wire when not in use; this switch is here used rather to prevent any liability of a burn-out due to an accidental overload, than to eliminate errors arising from the interior heating of the instrument. By means of a small, hard rubber thumb-screw projecting through the side of the instrument, a correct adjustment of the pointer for the zero position may be made without removing the case.

As previously stated it is customary in this type of alternating current ammeter to introduce a shunt of low resistance for the passage of the main portion of the current. In the portable meters this shunt is contained within the case of the instrument, but in the station type of alternating current ammeters the shunt constitutes a separate piece and can then be placed wherever it is most convenient, although it is usual on account of a saving in copper to limit the distance between the meter and shunt to 40 inches. By providing different shunts for a station ammeter the same instrument may be arranged to measure currents which differ considerably in value. It is then convenient to have separate graduations on the scale for each shunt, but if desired only one scale may be used and the readings thereon multiplied or divided according to the ratio between the shunts. In this manner an ammeter having a capacity of 5 amperes might, by the aid of a shunt, be made to have a capacity of 5,000 amperes.

Alternating current circuits are frequently designed to carry very high pressures. When the difference of potential employed is greater than 3,000 volts the shunts used in connection with station ammeters are replaced by series trans-

formers of which there are three types. One form known as the dry type is for use on circuits up to 10,000 volts with from 15 to 300 amperes of current; another form in which the coils are surrounded by oil is designed for pressures between 10,000 and 30,000 volts with currents up to 200 amperes, and the third form for pressures up to 10,000 volts with currents between 400 and 1,000 amperes is constructed of two coils of wire which surround one of the bus bars, the coils constituting the secondary winding of the transformer and the bus bar the primary. The passage of the current through the bus bar induces an electromotive force in the secondary coils. These coils being connected to the alternating current ammeter, the electromotive force causes a current to pass through the hot wire of the instrument and the effect thereby produced is a measure of the current strength. As the hot wires in all station ammeters of this type are designed to carry but 3 amperes, this is the maximum current that series transformers used for the purpose mentioned are constructed to give in their secondary coils.

Another form of alternating current ammeter frequently met with in practice is the Thompson inclined coil ammeter. It is simple in construction, consisting of one coil of wire connected between the binding posts and mounted in an inclined position of about 45 degrees with the horizontal. It is held in this position by an iron support which also contains the bearings for the movable part, together with the spiral springs attached thereto. The movable part is surrounded by this coil, and is composed of an oblong piece of soft sheet iron which acts as a core of the coil and is mounted on a spindle at an angle of 45 degrees. The spindle also carries the pointer which is fastened to it so that when the sheet iron piece lies in the plane of the coil the pointer will indicate zero on the scale. Upon the passage of a current through the meter, the magnetic field developed by the current in the inclined coil tends to cause the sheet iron piece to place itself at right angles to the plane of the coil, so that the lines of force may travel through it lengthwise. The change in position of the sheet iron causes the spindle to which it is attached to rotate, and consequently to deflect the pointer over the scale, the amount of deflection in any case being proportional to the number of amperes of current. As soon as the current is discontinued through the instrument the spiral springs attached to the top and bottom of the spindle pull it back so the pointer returns to its zero position.

The portable ammeter of this type is usually provided with an arrangement for causing the pointer to come rapidly to rest, for owing to the reversals of the current causing fluctuations of the pointer there is often considerable time occupied in obtaining a satisfactory reading. The apparatus which is used to reduce these fluctuations consists of a frame carrying a tightly stretched string, the frame and string together resembling a violin bow. This is mounted at right angles too, but on a rod which can be made to slide up and down in a vertical support by the respective pressure of a spring underneath, or by the pressure of the hand on top. The rod terminates in a button which projects through the case of the instrument, and when this is pressed down the string previously mentioned presses against the pointer, which latter travels in a horizontal position between the frame and the string, and the pressure tends to stop the vibrations of the pointer. Upon releasing the pressure of the hand or finger on the button, the compression of the spring forces the rod upward; the frame and string attached to this rod is therefore raised, and the pointer being released from contact with the string settles quickly to rest. It is, of course, necessary that when readings are taken the pointer be free to assume its own position as determined by the currents passing through the instrument.

The only remaining type of electrical measuring instrument to be considered is the wattmeter. This meter, like the others considered, is made in two forms, so there are portable wattmeters and station wattmeters. The former are designed to measure the value of the electrical power in watts supplied to a circuit at any one time, whereas the latter are designed to record these values for a given length of time. The portable wattmeter contains two main circuits, one of which is of heavy wire to be connected in series with the wires of the outside circuit and serves to measure the current in amperes, while the other circuit through the meter is of fine wire to be bridged across the load and serves to measure the pressure of volts. Binding posts are, of course, provided for connection to each of these circuits. The heavy wire circuit for measuring the current is simply used for establishing a field within which a movable coil is mounted. The fine wire circuit for measuring the pressure is also formed into two coils for developing a field, but these coils are wound in opposite directions to those composed of fine wire in order to neutralize the deflection that would otherwise be caused when the load circuit was open, by the movable coil which carries the pointer, and also forms a part of the fine wire circuit. A deflection of the pointer over the scale indicating a certain number of watts with simply t he pressure coil in circuit would be incorrect, since with zero current the number of watts which are proportional to the product of volts and amperes, should also be zero. The pressure circuit contains in addition two field coils and the fine wire movable coil, a key for opening and closing this circuit, and a high resistance, the latter of which serves the same purpose as the high resistance introduced in any voltmeter.

It is therefore obvious from the construction that a portable wattmeter is in reality an alternating current voltmeter and an ammeter combined into one instrument. As in the other instruments described, spiral springs attached to the movable coil cause it and the pointer mounted thereon to return to their respective zero positions when the circuit through the instrument is opened. If it be desired to increase the capacity of this wattmeter, a multiplier used in connection with the pressure circuit may be used to accomplish the result in the same manner as with direct or alternating current voltmeters.

On many switchboards, station wattmeters, or recording wattmeters as they are usually termed, are installed to measure and record on dials attached to the instrument the number of watt hours of power supplied to the consumers. By watt hours is meant the product of the pressure in volts, the current in amperes, and the duration of flow in hours. The recording wattmeter is in reality a small electric motor. The only special feature introduced in its construction is in the field magnets which are formed by coils of wire without iron cores. These coils are connected in series with the wires of the outside circuit for obtaining the effect of the current, while the armature winding is by means of small platinum tipped brushes and a commutator, supplied with the main voltage. A high resistance is introduced in the pressure circuit as in the previous case, and at the lower part of the vertical spindle upon which the armature is mounted a flat copper disk is fastened. This disk therefore revolves with the armature, and travels between the pole pieces of two permanent magnets mounted on the base of the meter. The lines of force of the permanent magnets being cut by the disk as it rotates, causes a difference of potential to be established in the disk, and this in turn causes eddy currents, which reacting on the iron of

the magnets exert a retarding influence on the motion of the plate. The effect thereby produced is precisely the same as a load on the motor. This increases the current through the motor, but since the eddy currents increase as the square of the speed, their effect entirely neutralizes that caused by a greater field strength, so that the speed of the armature in revolutions per minute is directly proportional to the current passing.

By means of a worm gear the motion of the armature shaft or spindle is communicated to a series of counters which are mounted to the top of the frame, and these are geared together in a ten to one ratio so that the number of watt hours may be read directly in tens, hundreds, thousands, etc. Sometimes the readings on the dials of the counters must be multiplied by a constant in order to obtain the correct number of watt hours. The constant is rendered necessary when it is desired to keep the speed of the armature at the same value regardless of the size of the meter, and the dials on all instruments also of the same size. Owing to the absence of iron in the construction of this wattmeter, it may be used on alternating current circuits as well as on direct current circuits with no alterations whatsoever.

With careful usage the recording wattmeter will not be found troublesome. The most common defects are excessive pressure of the brushes on the commutator, or abnormal friction at the lower bearing. The former trouble may be remedied by properly adjusting the brush holders, but the latter defect usually necessitates the substitution of a new jewel for the bearing, in place of the old one. If it be found that the indications on the dials of the counters are lower than they really ought to be, the speed of the armature should be increased by moving the magnets nearer the center of the disk. In this position there are less lines of force cut by the revolving disk, so that the load on the motor is diminished and the speed consequently increased.

RADIUM.*

BY PROF. R. A. MILLIKEN.

Roentgen's discovery of the X-rays would not have caused popular interest had it not been associated with the suggestion of the possibility of taking photographs of the human skeleton, and that idea was so strange, so uncanny at the time, that the discovery immediately took to itself wings, and inside of two weeks had set the whole world, popular as well as scientific, agog, and physicists began to experiment on these strange new rays. As a result of all this experimentation, very little that was new was added to our stock of knowledge regarding the nature of X-rays, for X-rays are now practically as unknown a quantity as they were when Roentgen first discovered them; but as is so often the case, this wave of experimentation bore fruit in unexpected directions, and one of the side products of that experimentation was a discovery in many respects infinitely more important, the discovery of the fact of radio-activity.

It came about in this way: When a discharge passes through an X-ray tube you are all aware, I presume, that the tube lights up with a sort of greenish light, which is called in physics a fluorescent light. X-ray photographs were taken by exposing a photographic plate with a hand in front of a tube of this sort, and the suggestion was early made that the X-rays themselves might be due to some sort of rays due to this greenish fluorescence, and, if so, we ought to get X-rays from other substances.

Now there are a number of minerals in nature, particularly uranium, which have this property of glowing with a yellowish green light when exposed to the actinic rays of the sun.

It was only a few months after Roentgen announced his discovery when Henry Becquerel made a radiograph with uranium rays, exactly the same as is done with the X-rays, except that that the exposure required was much longer, and by means of his experiments the discovery was made of the phenomenon of radio-activity which has added so much to our interpretation of the constitution of matter.

Some months after this Madame Curie, who is one of the few women who has ever attained eminence in the pursuit of science, but who must be placed in the front ranks of scientists of the present day, investigated all the then known elements in order to see whether any of the others of them possessed the strange properties which Becquerel had found in uranium, and she found that thorium and all its compounds (and that is one of the ingredients of our ordinary Welsbach mantle), and none of the other known elements possessed this property of radio-activity.

But in connection with this investigation she noticed one strange thing, and that is, that pitchblende, the crude ore from which uranium is obtained and which consists largely of uranium oxide, had the property of discharging electricity about four times as fast as pure uranium salt, or pure thorium salt, and she inferred from this that the discharging effect of the pitchblende was not due to the uranium alone in it, but that it must be due to some hitherto unknown element which had the same property which uranium possessed. She therefore proceeded by qualitative analysis to separate the 20 or more different ingredients contained in pitchblende. The search was very difficult, but ended triumphantly for Madame Curie, in the separation from two to three tons of pitchblende of two or three grains of an exceedingly active substance which she named radium, and which has recently become one of the wonders of the world, because of its most remarkable properties; although they are in no way different from properties of uranium and thorium, except that it has those properties in a higher degree.

I have 10 milligrams of pure radium bromide, which have been obtained by this extremely difficult process. This is so small an amount that it does not seem to be much of anything, yet this costs on the market $60.

Now I must call your attention away, in order to explain the properties of radium and radio-active substances, from the immediate consideratian of radio-activity to some of the other discoveries that followed upon the discovery of the X-rays, and were a consequence of them, because we shall have to understand the properties of what are called cathode rays to understand how people experimented upon these rays from radio-active substances to determine their nature.

For a long time there was much dispute as to what the nature of cathode rays was; they were thought by some to be some form of invisible light rays, being propogated in straight lines; others maintained that these rays were not light rays at all, that is, they had nothing to do with the ether, but that they consisted of streams of particles shot with enormous velocities in straight lines through the tube.

In 1898 a number of experiments were performed which show that the cathode rays are not light rays, but that they are projected particles. In all such circumstances a body which is put in the path of those rays is negatively charged, showing that they are negatively charged particles; and they are repelled by the negative and attracted by the positive pole of a magnet.

These experiments show that the cathode rays consist of negatively charged particles expelled at enormous velocities

*Lecture delivered at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

from the negative electrode in the cathode tube. This is now an admitted fact.

We can calculate from the amount of deflection of a magnet of known strength and the amount of deflectien from electrical charges of known strength, first the velocity of the particles, and second their mass. When that calculation is made it shows the velocity is something like 20,000 miles per sccond. But the size of the particles is a surprising thing. They are not atoms and they are not molecules, but their size is about 1-1,000 of an ordinary hydrogen atom, the smallest atom thus far known.

These experiments upon cathode rays showed that under some circumstances particles exist which are smaller than the smallest atoms known to chemistry, and very much smaller, and they suggested for the first time in the history of man the possibility of breaking up the atom into small parts.

I will introduce here a speculation resting on a certain amount of experimental evidence, on account of the fact that the size of these cathode particles is always the same; no matter what the nature of the gas or electrode is, it is certain that these particles are constituents of all known metals and of all the gases that can be experimented upon here, and therefore probably of all substances. J. J. Thompson has brought forward, therefore, the hypothesis that we have here the primordial atom from which all our ordinary atoms are built up.

The hypothesis therefore is the atom of hydrogen consists of about a thousand of these cathode particles called electrons, and the mercury atom would be about 200,000, and the oxygen atom 16,000. That is, the various atoms of chemistry would simply be complexes of these cathode particles, each atom containing a number corresponding to its atomic weight.

(To be continued.)

Meeting of Standard Underground Cable Company.

The annual meeting of the stockholders of the Standard Underground Cable Company was held at the general offices of the company in the Westinghouse Building, Pittsburg, Pa., on January 26.

The statement of the company's operations for the year was presented, showing that the company did a gross business of nearly $9,000,000 during the year 1903, that dividends were paid on its capital stock aggregating 12 per cent., and that the company's assets aggregate the handsome sum of $3,604,457, with only $375,344 of liabilities, apart from capital stock. It has no outstanding notes, mortgages, bonds or preferred stock.

The board of directors elected for the ensuing year is as follows: Mark W. Watson, John B. Jackson, James H. Willock, Robert Pitcairn, J. N. Davidson, John Moorhead, B. F. Jones, Jr., Joseph W. Marsh and W. A. Conner. The only change in the board is represented by the election of W. A. Conner, who has been at the head of the manufacturing department of the company since 1884.

The meeting of the board of directors for the purpose of organization was held on January 29 and the former officers were re-elected as follows: Mark W. Watson, president; Joseph W. Marsh, vice-president and general manager; Frank A. Rinehart, treasurer, and C. M. Hagen, auditor.

This company was the pioneer in the manufacture of underground cables for all classes of electric service, having been formally organized in January, 1882, although much experimental work had been done by Richard S. Waring, the founder of the company, prior to its organization. Its reputation for high class manufacture in each of its departments, comprising bare copper wire, weatherproof wires and cables, rubber insulated wires and cables, and both paper and rubber insulated lead covered cables for telephone, telegraph, electric light and power service, together with the favorable location of its factories, Perth Amboy, N. J., Pittsburg, Pa., and Oakland, Cal., and its strong financial condition, place it in a most favorable position to command a large business in its various lines.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JANUARY 26, 1904.

Electric Railways and Appliances.

750,247. Mono-Railway and Truck Therefor. Lina Beecher, Batavia, N. Y., assignor to the Beecher Construction Company. Filed March 6, 1903.

750,296. Electric Railway Signal. William V. Moak, Albany, N. Y. Filed Dec. 8, 1902.

750,368. Trolley for Electric-Railway Cars. Charles J. Johnson, St. Louis, Mo., assignor of one-half to Charles W. Benedict, same place. Filed May 14, 1903.

750,458. Overhead-Trolley Attachment. Charles Holyland, Sr. Pittsburg, Pa. Filed June 6, 1903.

750,510. Process of Forming Electrical Rail-Bonds Directly in Place on the Rails. William H. Wherry, Cleveland, O. Filed Jan. 22, 1903. Renewed Oct. 1, 1903.

750,719. Car-Fender. Emil Sprich, St. Louis, Mo. Filed Aug. 28, 1903.

750,733. Trolley-Pole. John J. Tartt, Los Angeles, Cal. Filed March 30, 1903.

Electric Lights and Appliances.

750,554. Ballast Device for Vapor-Lamps. Henry N. Potter, New Rochelle, N. Y., assignor, by mesne assignments, to the Cooper Hewitt Electric Company. Filed Oct. 19, 1901.

750,720. Incandescent Lamp. Walter A. Springall, San Antonio, Tex. Filed June 25, 1903.

Electrical Machinery and Apparatus.

750,261. Brake for Vehicles. William H. Cooley, Brockport, N. Y. Filed D 1902.

750,370. Electric Gear for Cranes. Otto Kammerer, Charlottenburg, Germany. Filed May 11, 1900.

750,421-750,422. Electric Brake. George C. Anthon, Medford, Mass., assignor, by mesne assignments, to the Algonquin Electric Brake Corporation, Boston, Mass. Filed Nov. 30, 1901, and April 11, 1902.

750,434. Electric Brake. Perley P. Crafts, Boston, Mass., assignor, by mesne assignments, to the Algonquin Electric Brake Corporation, same place. Fled Nov. 29, 1899.

750,509. Electrical Conductor. William H. Wherry, Cleveland, O. Filed Nov. 3, 1902. Renewed Oct. 1, 1903.

750,525. Transformer. Augustine R. Everest, Lynn, Mass., assignor to the General Electric Company. Filed Aug. 11, 1902.

750,765. Electric Motor. Thaddeus W. Heermans, Chicago, Ill. Original application filed Dec. 4, 1899. Divided and this application filed Jan. 22, 1900.

Telephones and Telephone Apparatus

750,309. Annunciator. Lambert Schmidt, Weehawken, N. J. Filed Aug. 28, 1901.

750,689. Plug for Telephone-Switchboards. Frank D. Pearne, Chicago, Ill., assignor to Pearne, Krum & Co., same place. Filed April 20, 1903.

750,704. Telephone Switching and Signaling Apparatus. Malcolm C. Rorty, Dedham, Mass., assignor to the American Telephone & Telegraph Company. Filed Jan. 3, 1902.

750,769-750,770. Telephone-Service Apparatus. Uriah S. Jackson, Ossipee, N. H., assignor to the Superior Autumatic Telephone Company, Boston, Mass. Filed May 31, 1902, and April 22, 1903.

Miscellaneous.

750,250. Electric Battery. Winfield S. Bryan, Cincinnati, O. Filed Sept. 28, 1903.

750,268-750,269-750,270. Electric Signaling Apparatus. William E. Decrow, Boston, Mass. assignor to the Gamewell Fire Alarm Telegraph Company. Filed April 29, 1901, June 17, 1901, Sept. 27, 1901.

750,289. Telegraph Instrument Stand. James W. Leech, Staunton, Va. Filed Jan. 6, 1903.

750,361. Electrometallurgy of Iron or Steel. Henri Harmet, St. Etienne, France. Filed Sept. 30, 1901.

750,429. Wireless Electric Transmission of Signals Over Surfaces. Ferdinand Braun, Strassburg, Germany. Filed Feb. 6, 1899.

750,454. System of Electrical Distribution. Josef H. Hallberg, New York City. Filed Oct. 16, 1903.

750,471. System of Electrical Generation, Distribution and Control. Lamar Lyndon, New York City, and Elmer A. Sperry, Cleveland, O., assignors to the National Battery Company, Jersey City, N. J. Filed Jan. 17, 1903.

750,492. Electric Clock. Fred Schmidt, Oak Station, Pa., assignor of one-half to Henry Bauer, Lock No. 3, Allegheny County, Pa. Filed May 9, 1903.

750,496. Spark Telegraphy. Adolf Slaby, Charlottenburg and Georg G. Arco, Berlin, Germany. Filed April 9, 1901.

750,497-750,500. System of Electrical Generation, Distribution and Control. Elmer A. Sperry, Cleveland, O., assignor to the National Battery Company, Jersey City, N. J., and Buffalo N. Y. Filed Dec. 5, 1902, July 1, 1903.

750,498-750,499. Power Transmitting Mechanism. Elmer A. Sperry, Cleveland, O., assignor to the National Battery Company, Jersey City, N. J., and Buffalo, N. Y. Filed March 5, 1903.

750,549-750,550. System of Electrical Generation, Distribution and Control. Lamar Lyndon, New York City, assignor to the National Battery Company, Jersey City, and Buffalo, N. Y. Filed Jan, 22, 1903. Renewed Dec. 8, 1903. Filed July 18, 1903.

750,569. Electric Time Alarm. Theophilous L. Bear, Camden, N. J. Filed Sept. 27, 1901. Renewed Aug. 8, 1903.

750,584. Process of Administering Electrical Vibrations. Fred H. Brown, Los Angeles, Cal. Filed Aug. 25, 1902.

750,646. Combined Electrical Battery Receptacle and Bell Support. William A. Harvey, Scranton, Pa., assignor of two-thirds to Charles Schlager and Walter L. Schlager, same place. Filed Sept. 9, 1903.

750,716. Electric Fan. Adolph T. Smith, New York City, assignor,of one-half to Myron B. Matthews, Passaic, N. J. Filed Aug. 10, 1903.

750,722. Insulator. Louis Steinberger, New York City. Filed May 25, 1903.

750,753. Electric Furnace. Ramon O. Contarda [illegible] France. Filed Aug. 24, 190[illegible]

Reissue.

12,195 Electrical Accumulator. Chaimsonovitz P. Elieson and Vladimir de Bobinsky, Paris, France. Filed Oct 26, 1903. Original No. 692,433, dated Feb. 4, 1902.

THE TELEPHONE WORLD.

Independent Companies Hold Meeting in Nebraska.

The Independent Telephone Association met in Lincoln last month. The programme was composed of the opening address by the president of the State Association, I. D. Clark, of Papillion. Reports of secretary and of committees, and work of a more routine nature followed. The paper of the afternoon session was an interesting one on the subject "Selective Calling on Party Lines," by J. E. Adamson, of Broken Bow, and W. J. Staadelman, of Kearney. The points brought out in the paper were discussed by the members and the new ideas embodied in the reading met with keen approval.

The prime object of the convention was to arrange for a systematic connection of all the Independent lines of the State in such a manner that a call from Lincoln may be made with Fairbury, Plattsmouth, Hastings or any other city where Independent lines are now in operation.

E. C. Hansen, secretary of the Independent Telephone Association, said that plans were on foot for the connecting up every part of the State.

At a meeting of the business men of Springfield, Minn., it was decided to organize the Farmers & Citizens' Mutual Telephone Company. The incorporation will be capitalized at $25,000. The incorporators are: J. S. Schroder, William G. Frank, A. G. Anderson, Ed. J. Fernholf, C. A. Hintz, Albert Prahl, Ernest Altermott. Besides a local system, rural lines will be built at once to connect all of the neighboring towns. The life of the corporation is fixed at 30 years.

The Hopkinsville, Ky., Home Telephone Company was organized a short time ago, by electing R. E. Cooper, president; George H. Metheany, of Lima, O., vice-president; Joseph F. Garnett; treasurer; and F. G. Hoge, secretary. The contract was let to the Ideal Construction Cmpany of Lima, O., for a complete telephone exchange. The company is capitalized at $100,000.

An ordinance was recently adopted granting to Wm. Lehn a franchise to erect poles and wires for the transmission of electricity for telephone and telegraph purposes along the public roads of Sonoma County, Cal., also to the Russian River & Windsor Telephone Company for the same purpose.

A new section of switchboard is being put in at the exchange of the Mutual Telephone Company of Shelbyville, Ind., which will increase the capacity to 1,100 'phones. The lines now between that city and Indianapolis are not sufficient for the service, and a third one is being built.

The Northern Nevada Telephone & Telegraph Company, incorporated by J. G. Taylor, R. H. Mallett and others, capitalized at $10,000, has a telephone line between Tuscarora, Edgemont, White Rock and Columbia, and will extend to other points north.

An ordinance has been passed granting to the Utah Independent Telephone Company a franchise to erect and maintain telephone lines upon the public highways of Weber County.

Reorganizing the Michigan Telephone Company.

The first step in the reorganization of the Michigan Telephone Company, the properties of which were purchased by N. W. Harris & Co., on behalf of a bondholders committee recently, was taken last week in the incorporation of the Michigan State Telephone Company under the laws of that State, with a capital of $25,000 divided into $10,000 accumulative preferred stock and $15,000 common. Under the charter the right is reserved to increase the capital stock, and the voting powers on both kinds of stock are equal.

The incorporaters and directors are William A. Jackson, a founder of the Michigan Telephone Company; John T. Shaw, cashier of the First National Bank of Detroit; James Cullen, and Elliott G. Stevenson, a partner of Don M. Dickinson, who was counsel for the bondholders in Detroit. It is said that the new company will take over the properties of the old one, this process necessitating the satisfaction of the bond claims held by the bondholders as present owners of the property.

The first annual meeting of the York State Telephone Company, since its organization one year ago, was recently held in Binghamton, N. Y. The following officers were elected; President, W. D. Barnard; vice-president, Edward Davis; secretary and treasurer, Robert M. Dougal; general superintendent, George B. Wright. The report of Vice-president Davis to the stockholders showed that the company had increased the number of telephones from 2,461 at this time last year, to 3,617 at present, a growth of 50 per cent. in one year.

Articles of incorporation of a telephone company to operate in Genesee and Orleans Counties, N. Y., with an exchange at Byron, were lately filed with the county clerk. The capital stock is $1,200, and the stockholders are E. I. Cook, I. C. H. Cook, Marshall H. Cook, Burt H. Gall, Charles H. Green, Dr. Messenger, H. C. Norton, Dr. Prince, A. G. Steele, H. C. Walker, F. C. Walker and I. W. White.

The Canton, Pa., council has granted a franchise to the Canton & Leroy Telephone Company, which company will install its system as soon as the frost is out of the ground. While this company is purely a mutual company it will form part of a system of former telephone lines which will reach considerable proportions

At the annual meeting of the stockholders of the Colonial Telephone Company recently held in Newburgh, N.Y., officers were re-elected as follows: S. V Schoonmaker, president; Wm. G. Taggart, vice-president; H. A. Bartlett, treasurer; George G. Otis, secretary and general manager.

The Rhinelander, Wis., Mutual Telephone Company by its president, Samuel S. Miller, and its secretary, H. L. Crawford, lately filed an amendment increasing its capital from $5,000 to $10,000.

An Independent telephone system is to be installed connecting Jackson, Ann Arbor and Ypsilanti, Mich.

Independent Company Busy in New York State.

The Wayne-Monroe Telephone Company has invaded Sodus, and a big exchange will be built, connecting all the villages and towns, using Sodus as the center. General Manager Driscoll, of Rochester, Dr. J. S. Brandt, of Ontario, and J. L. Transue, of Williamson, directors of the company, have signed contracts in Sodus. It has been rumored for some time that this company would invade Sodus.

The Wayne-Monroe Company is known as the Independent Company, and it has recently installed systems throughout the towns of Ontario, Williamson, Walworth and Macedon, in connection with the Independent exchange at Newark, Lyons and Clyde. Its trunk line was completed a short time ago, and it is now connected with Rochester through the Home Company and with 50,000 telephones in Western New York. The line has already been extended to East Williamson, four miles west of Sodus, where a large number of subscribers have been received. The line will be extended through to Oswego without delay. Twenty miles of line will make the connection, as the system extends 20 miles west of that city at present. Oswego is now reached via Syracuse.

The subscribers, of the Shortsville, N. Y., Telephone Company will soon have direct communication with Canandaigua, as an arrangement has been made between the Red Jacket Telephone Company and the Inter-Ocean Company, which permits the latter company to string two pair of wires upon the poles belonging to the former company from Shortsville to Wadsworth's Corners, in the town of Hopewell, at which point the Inter-Ocean will occupy the poles of the Lawson to Canandaigua.

The Tri-State Telephone Company has connected up its through line from Connellsville, Pa., to Wheeling, W. Va. At the latter place the line connects with the National Telephone Company. The circuit now connects with the towns of Fairmont, Morgantown, Clarksburg and Mannington, and numerous other smaller towns. Going westward the connections have been made with Steubenville and St. Clairsville.

H. H. Yard was lately granted a franchise to build a telephone or telegraph line along the public roads of Plumas County, Cal.

The Madison, N. Y., Mutual Telephone Company has been incorporated with $1,500 capital stock.

The Battle Creek, Mich., Telephone Company has decided to install the automatic system.

Telephone Incorporations.

The Citizens' Telephone Company, Zionsville, Ind. Capital stock, $15,000. Officers. President, James O. Hurst; secretary and treasurer, H. F. Gallimore.

The Hollansburg Home Telephone Company, Hollansburg, O. Capital stock, $10,000. Incorporators: G. W. Harley, S. V. McKesel, G. U. Wolf, W. A. Chenoweth, C. A. Brown and J. E. Irelan

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alhambra, Cal.—Bids for an electric light and power franchise for this city will be opened by the trustees February 9.

Bay City, Mich.—April 4 the electors of the city will vote upon a proposition to bond the city for $50,000, in order that money may be obtained to defray the expenses to making additions to the city's electric lighting plant.

Black River Falls, Wis.—The special election held here recently to vote on the question of bonding the city for $25,000, to purchase the electric light plant, was carried.

Braddock, Pa.—A committee has been appointed to consider the practicability and cost of a municipal electric light plant.

Catorce, Mex.—An electric light plant is to be installed at the Delores Trompeta Mine, situated in this district.

Cicero, Ind.—A new electric light plant will be erected here.

Coeymans, N. Y.—C. M. Tompkins is at the head of a movement by the citizens asking the town board to establish on electric lighting system in the district.

Guthrie, Okla.—A plan is on foot to enlarge and improve the Guthrie electric light plant.

Index, Wash.—F. G. Dorety, backed by San Francisco and New York capitalists, says he intends to build a light and power plant near here.

Irvington, N. J.—A proposition has been made to the council offering to light this town for $9 a lamp, the town to furnish the system. William L. Gloreiux may be able to furnish information.

Jacksonville, Fla.—Negotiations are reported under way for the purchase of the electric light plant of the Jacksonville Electric Company.

Kirkwood, Ill.—J. F. White and Dr. Kyler propose to put in a heating and electric light plant here to cost $8,000.

Millen, Ga.—This city is still negotiating with R. E. Riley, who owns an interest in the Millen cotton mill, to establish an electric light plant here.

Monticello, Wis.—An electric light plant is one of the possibilities of this city.

Negaunee, Mich.—All bids are reported as rejected for new electrical machinery for the municipal electric lighting plant. New specifications are to be drawn and new bids invited, according to reports. John Davey is city engineer.

Plainfield, Ill.—The village board at its next meeting will take up the electric light proposition.

Santiago, Cuba.—It is stated that Eduardo J. Chibas, who is the engineer for the proposed electric plant and tramway here, will probably let the contracts in about two months for the electric light plant. There will be 8,000 16 cp. incandescent and 100 1,200 cp. arc lights, and the plant will cost about $200,000. The commencement of work depends upon the city awarding to Mr. Chibas a contract for the lighting of the city, terms for which are now being considered.

St. Joseph, Mich.—It is reported that the proprietors of Higham Park contemplate placing an electric lighting plant in the park.

Tallahassee, Fla.—Bonds to the amount of $40,000 will be issued for sewerage purposes, also bonds for electric light purposes.

Warrensburg, Ill.—There is some talk of establishing an electric light plant in this village.

Wilkes-Barre, Pa.—A meeting will be held here soon for the purpose of considering the advisability of granting a franchise to the Ashley Electric Light & Power Company.

Waterville, Wash.—The city council has entered into a 15-year contract with George H. Gray & Son, of Entiat, to furnish electric light and power to the city at $50 per horse power per annum, the city to use 50 hp. or more. The plant is to be in operation by September.

STREET RAILWAYS.

Appleton, Wis.—The Outagamie Traction Company has been incorporated to build and operate an electric railway with a capital stock of $30.000. The directors are A. Hawes, Thomas L. Pearson and others.

Belleville, Ill.—The Belleville council has granted a franchise to the Southern Illinois Electric Railway Company to operate an electric line.

Benton Harbor, Mich.—J. G. McMichael, the street railway promoter, was recently given a franchise for a new electric road from this city to Dowagiac.

Colfax, Wash.—The Whitman Railway & Power Company has been incorporated with a capital of $500,000. The company will build an electric road from Palous to this city.

Deerfield, Mich.—An effort is being made to obtain right of way from Britton through this place for an electric railway to connect with the Toledo line at Petersburg. A double track is to be laid and everything completed by summer.

Defiance, O.—A company headed by several local men, combined with the officials of the Toledo-Indiana Electric Railway, has been formed to build a line from this city to Adrian, Mich. Peter Kettenring, head of the Defiance Machine Works, is interested.

Elizabeth, N. J.—The Morgan County Traction Company has applied for a franchise in the township of Union.

Mechanic Falls, Me.—An electric road will be built between here and Lewiston.

Norfolk, Va.—A company has been chartered here to build an electric railway to Elizabeth City, N. C.

Odessa, Del.—There is some talk of a trolley line from Stanton to this place, running through to St. Georges. The object is to connect Stanton, which is the terminus of one of the suburban lines of the Wilmington City Railway Company, with Odessa.

Rochester, N. Y.—This city gives promise of becoming a great terminal for electric railways. No less than four more trolley roads to run to this city are planned. These are the Ridge Road Railway, which will connect with the Lake avenue tracks of the Rochester Railway Company; the Williamsville & Buffalo Railroad, which has laid tracks to Batavia; the Rochester, Syracuse & Eastern Railway, which will enter the city via University avenue, and the Albion Electric Railway, which is to connect with the Lyell avenue tracks of the Rochester Railway Company.

Russellville, Ky.—J. R. Reynolds, of this city, represents the Southern Kentucky Interurban Traction & Power Company, which is incorporated under the laws of New Jersey. He is procuring rights of way from here along the Russellville and Gallatin highway via Middleton and Sulphur Springs to Franklin. The object is to build an electric rail line from here to Franklin He pays $100 for each grant, and guarantees that if work is not under full headway in one year the lands revert to the venders.

San Jose, Cal.—Sealed bids will be received by Joseph A. Belloli, Jr., city clerk, up to 3 P.M. February 15, for a franchise to construct and operate an electric railroad over certain streets in this city for a period of 50 years.

Salem, O.—The Stark Electric Railway Company was lately granted a franchise through this city.

Seymour, Ind.—Col. A. E. Boone is planning a new electric railway line.

Spokane, Wash.—A. J. Smith, Samuel J. Crutcher and A. H. Gaston, of Pine City, will build an electric line from this city to Colfax.

Tacoma, Wash.—The Northern Pacific Railroad Company, after operating its South Tacoma car shops for years with steam, has decided to introduce electricity as a motive power. The change will be made some time before May 1.

Toledo, O.—The Lake Erie & Southern Traction Company is the name of a company recently incorporated to construct an electric railway line from this city to Columbus.

Utica, N. Y.—Paul Smith, the veteran Adirondack hotel man, is authority for the statement that next summer will see the beginning of construction work on an extensive system of electric roads in the north woods. The power for the proposed road will be taken from Franklin Falls in the Saranac River, 20 miles away. It is understood that the plans provide for the connection of Saranac Lake with all the villages thereabouts, as well as with this city.

Wabash, Ind.—G. A. Bartholomew, L. A. Smartt and the Municipal Bond & Securities Company of Cincinnati, are interested in the proposed traction company from this city to Rochester.

Watsonville, Cal.—W. J. Rogers has applied for a franchise to construct and operate an electric railway over certain streets in this city. Bids for said franchise will be received up to 8 P.M., February 17. S. W. Coffman, city clerk.

West Newton, Pa.—The Monongahela Traction Company is making preparations for the building of its lines from here to Jeannette.

POWER PLANTS.

Denver, Col.—The F. M. Davis Iron Works, builders of mining and milling machinery, propose installing a new electric power plant during this year at an approximate outlay of $25,000.

Westcliffe, Col.—The Bassick Company has under consideration the construction of an electric power plant on Grape Creek, near here, to furnish power for its machinery.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅜@12½c.; Lake 12½@12⅝c.; casting, 12¼@12⅜c.

There was a bear raid on Brooklyn Rapid Transit on Monday, based upon rumors of a new large bond issue.

Prominent New York capitalists have become identified with the United Electric Light & Power Company of Baltimore.

By agreement of both parties to the Chicago Union Traction suit, arguments will be heard by Judge Grosscup on March 1.

It is claimed that the Westinghouse Company's annual report will show an accumulated surplus of about 62 per cent. of its capital stock.

The New England Telephone & Telegraph Company has declared the regular quarterly dividend of $1.50 per share, payable February 15.

The fiscal year of the General Electric Company ended on Saturday. The total sales for the year are reported to have exceeded $40,000,000.

The market for copper on Monday was again inclined to weakness under a further reduction of ¼c. per pound in all grades. There was little demand for home consumption.

Announcement has been made that arrangements have been concluded for the building of a third-rail street car system between Elmira and Corning, N. Y., by Mansfield & Powers of Troy.

W. C. McMillan of the Union Trust Company of Detroit will be chairman of the board of the reorganized Michigan Telephone Company. The new company will be financed for $10,000,000.

The Twin City Rapid Transit Company has declared a regular quarterly dividend of 1¼ per cent. on the common stock, payable February 3. Books close to-day and reopen February 16.

Eastern capitalists have purchased the property of the Lawrence Telephone Company, having exchanges at Ironton, O., Ashland, Catlettsburg, Russell and Rush, Ky., and minor points.

It has been learned from thoroughly trustworthy sources that at least two directors of the Metropolitan Elevated Company of Chicago have signified their intention of resigning unless the agitation against the management ceases.

The Columbus Public Service Company, with an authorized capital of $1,500,000, has been incorporated at Trenton, N. J., to make and distribute heat, light and power. The incorporators are Horace S. Gould and H. O. Coughlan, of New York; Joseph M. Mitchell, of Newark; B. S. Lantz, of Brooklyn, and Louis B. Dailey, of Jersey City.

A. E. Appleyard & Co. of Boston have completed arrangements for the consolidation of four of their electric lines in Ohio under the name of the Ohio Union Traction Company. These four companies operate 200 miles of track and have a total capital of $5,000,000. Five per cent. bonds will be issued to take up $3,250,000 of preferred stock.

The Massachusetts Railroad Commissioners have given their approval to the sale of the Framingham, Southboro & Marlboro Street Railway Company to the Boston & Worcester Street Railway Company and have authorized the latter company to issue 1,850 new shares to consummate the sale, the said new shares to be exchanged share for share for the capital stock of the Framingham, Southboro & Marlboro Street Railway.

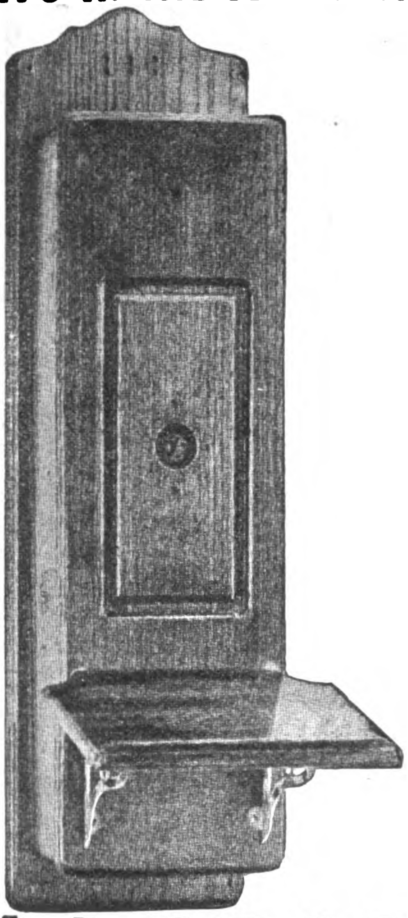
We Make All Kinds of Boxes and Cabinets for the Electrical Trade



WE CAN ACCURATELY DRILL THEM FOR YOU SO THAT THEY ARE ALL READY FOR THE ASSEMBLING OF THE METAL PARTS. SEND US YOUR SPECIFICATIONS AND LET US QUOTE YOU.

Our Specialty is

High Grade Finish and Accurate Work.

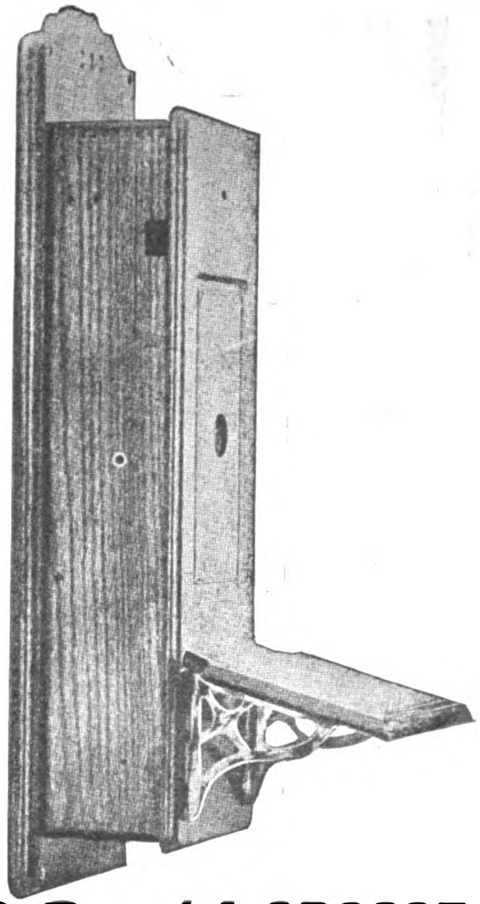
These two cuts show our new Compact Cabinet with nickel-plated brackets supporting the paper shelf. The paper shelf and nickel-plated brackets are removed in shipping. Doing this saves room, avoids scratching, and facilitates shipping.

The nickle-plated brackets make a handsome contrast with the highly finished quarter-sawed oak front and paper shelf.

We Can Furnish These Cabinets All Drilled Ready for the Working Parts.

In addition to the above cabinet, we make all of the standard styles including

CENTRAL ENERGY, MAGNETO BOXES, CABINETS FOR RESIDENCE PHONES, ETC.



LA CROSSE CABINET CO., LA CROSSE, WIS.

GONZALOS OIL CO.,

170 West Broadway, New York.

REFINERS OF BUENA VENTURA BRANDS OF

Lubricating Oils and Compounds

Floor Oils and Greases.

TELEPHONE 4479 J FRANKLIN.

EDITORIAL NOTES.

Was it the Man or the Machine? The fall of an electrically operated elevator last week in a nineteen story Broadway office building, situated on the lower part of Manhattan Island, again brings up the question as to where the blame lies—with the man or the machine?

Fortunately the elevator only fell from the fifth floor, which, however, resulted in five persons being more or less seriously injured.

Naturally the elevator company will claim the operator was to blame, and the fact that it was the man's first day on that type of elevator would seem at first glance to bear out the company's assertion. On the other hand the man was what might be termed an experienced operator, having run various types of elevators for twelve years.

The type of electric elevator that fell requires, if all the mechanism is in working order, but three motions of a hand lever to cause it to ascend, stop and descend. When the lever is upright brakes are supposed to hold the car so that it cannot move. An experienced elevator man ought therefore to have little or no trouble in operating such an elevator even for the first time, providing, as already stated, all the mechanism is in good working order. A new operator would probably not be able at first to make the stops at the various floors as nicely as an experienced hand, but it is hard to see how if everything is in order he could cause it to fall five stories when the simple act of bringing the lever upright should stop the car.

We think that a thorough investigation will reveal the fact that the machinery was not in good working order.

But whether the operator was to blame or not it is in place to say a few words about elevator men in general. In 1898 the city compelled elevator men to be examined. It is true the examination left much to be desired, but the moral effect was good. An elevator man before going before the board *generally* took the trouble to study up the working of his elevator to a greater or less extent, which did him no harm. A large number of so-called elevator men, operating lifts in this city at the present time, are nothing more than boys, who have no more idea as to what would happen or what does happen if they yank the elevator rope hard than an unborn child. It is about time the city held another examination for elevator men, and it is to be hoped that the questions asked will be of more vital importance than those asked six years ago.

* * *

Electricity in the Navy. Some interesting facts are contained in the report of Lieut. Harry George, U. S. Navy, inspector of electrical appliances. Among other things it is shown that the sum of $376,964 was expended during the last fiscal year upon the installation and repair of electrical appliances on shipboard, and $212,836 on the manufacture and repair of electrical apparatus and appliances in navy yard shops. Alterations, additions and repairs to the electrical appliances of 119 naval vessels were made during the past year.

A portable searchlight has been designed for use in connection with coast-defense districts and the occupation of advanced naval bases. In general, the apparatus consists of two units, each mounted on broad threadwheels, suitable for operation in a rough country, and so constructed that it can be readily assembled or disassembled for transportation in ships' boats.

During the past year the Bureau of

Equipment of the Navy Department has acquired two sets of the Ducretet loud-speaking telephone, marine type, extensively used in the French Navy. This apparatus, together with a set of the Graham instruments, English Navy type, will be tested in competition with the Bell and other instruments of American manufacture and installed on board ship for further observation.

A new system of battery fire control has been designed during the year to meet the requirements of the Bureau of Ordnance. In this system the guns are divided into groups instead of by divisions, as heretofore, each group including all guns of practically the same nature and having the same arc of fire. The system possesses great flexibility and enables separate and distinct orders to be transmitted simultaneously to the various groups of guns.

The school at the New York Navy Yard for the instruction of enlisted men for the rate of electricians, with a view of detail on shipboard as dynamo tenders and for the care of electrical appliances, has been successfully conducted during the past year. It will soon be moved into more suitable quarters, with additional appliances, where it is anticipated it will be still more efficient.

* * *

Safety Device for the Park Avenue Tunnel.

That there shall be no more loss of life through fire in the Park Avenue tunnel of the New York Central Railroad is the intention of the management as well as of the State Railroad Commission. With a view to introducing proper safeguards a careful inspection of the tunnel has recently been made by Fire Chief Kruger and one of the State Railroad Commissioners. They plan to install whatever apparatus may be necessary to quickly extinguish any blaze that may arise, especial provision being made for the coming electrical operation of the road.

Referring to the matter one of the gentlemen is reported as saying that the plans now being prepared are designed not only to insure safety from fire so far as possible after the new system of electric traction shall have been installed in the tunnel, but to improve the situation even under existing conditions,

As we suggested some time ago in these columns in reference to the new subway, it might be a good idea to install in the Park avenue tunnel a system of overhead sprinklers which could immediately be turned on in the event of a collision and the cars taking fire.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Columbia, Harvard and Yale Universities and the Massachusetts Institute of Technology have reached an agreement by which a Western mine will be leased for the benefit of students of mining.

Messrs. Otto Blathy, Max Dery and Prof. Charles Zipernowsky have been elected members of honor of the Hungarian Society of Buda-Pest, in token of their distinguished services to electricity.

At a dinner given Friday evening by the Technology Club of this city, composed of the alumni of the Massachusetts Institute of Technology, the members indulged in "liquid sunshine," but none of the self-sacrificing scientists who drank the liquid became transparent afterward, although all were assured that, as a matter of fact, their interiors were thoroughly illuminated. A demonstration was afterwards given of the luminous effect of radium on willimite, kunzite and other minerals. Addresses were made by President Pritchett, Dr. Morton and Dr. Savage.

Two hundred all-metal cars have been ordered by the Interborough Rapid Transit Company for operation in the New York subway and they will be ready for use in March. It is said that these are the first all-steel cars ever built in the world, and the company asserts they assure the traveling public absolute safety from fire.

Dr. George F. Kunz of New York, special agent of the United States Geological Survey, has been appointed commissioner of the radium exhibit at the St. Louis Exposition, and has been authorized to prepare and procure material therefor, comprising radio-active substances of all kinds, and also exhibits to illustrate the action of radium compounds, ultra-violet light, and Roentgen rays upon mineral and chemical substances.

At the American Institute dinner tomorrow night at the Waldorf-Astoria, of which Thos. A. Edison will be the guest of honor, one end of the Commercial Cable Company's cable will be taken into the grand ball-room of the hotel, and will be connected to the table at which the inventor will sit. By means of the old quadruplex instrument which Mr. Edison used many years ago when he was a telegraph operator, and which has been in the museum of the Western Union Telegraph Company for a long time, he will send a message across the ocean to Marconi, who will try by means of some new instruments to reply across the ocean by the wireless method. Messages to all of the great scientists in both America and Europe will be sent from the room where the dinner will be held.

Rear-Admiral Melville, U. S. N., has been sent to Europe to study steam-turbine machinery, particularly for use in the new 4,000 ton scout ships of the navy.

A cable dispatch received from Prof. Michael Pupin of Columbia University, who is now in Berlin, announces his complete victory over the German postal administration on the contest to establish his patents of long distance and ocean telephone devices. The American rights to the invention have been sold to the American Bell Telephone Company, and Prof. Pupin made arrangements for the sale of the foreign rights to the firm of Siemens & Halske of Berlin in the event that he could establish his patents. A contest was joined in German courts by several private concerns and has been waged for four years.

The Western Union Telegraph Company is said to receive over $1,000,000 a year for keeping 70,000 clocks going on correct time. The clocks are set at noon each day by an automatic arrangement connected with the great sidereal clock in the National Observatory at Washington. A few minutes before noon every day business over the Western Union wires is suspended, and operators through the country put their instruments in shape to form an unbroken circuit from the obsertory to every place where ticks a clock to be electrically influenced. There is a hush over all the great telegraphic system Then the time ball strikes; and instantly the time message flashes over the wires.

A series of tests of four systems of wireless telegraphy will soon be made by warships in this vicinity. The progress of wireless telegraphy in the navy recently has been very satisfactory. In one case the flagship Kearsarge and the Minneapolis communicated with each other by the wireless method at a distance of 60 miles.

Plans are being made in automobile circles for the largest and longest endurance run ever held in this country. In connection with the endurance run itself, it is also hoped to hold a series of club runs, all to have St. Louis for their goal.

SPEED-TORQUE CHARACTERISTICS OF THE SINGLE-PHASE REPULSION MOTOR.*

BY WALTER I. SLICHTER.

The single-phase commutator motor has attracted considerable attention of late, as there is quite a demand in railway work as well as in numerous other lines for an alternating current motor that will start under a heavy load with a reasonable consumption of energy. At present it appears that a commutator motor is the only type that will fulfill these conditions.

For some months past the writer of this paper has been in charge of a series of experiments with various types of alternating current commutator motors. During these experiments much attention was given to the repulsion motor. It is the purpose of this paper to place before the Institute some of the results obtained, and to point out some of the characteristics of the motor which give future promise of making it a very prominent factor in some lines of electric railroading.

For the benefit of those not already familiar with this type of motor, it may be here stated that it is a single-phase commutating motor, resembling very much a regular direct current armature in an induction motor field. The resemblance to the induction motor is carried still further in that there is no electrical connection between the primary and secondary. This makes it possible to wind the primary for a high line voltage, while the voltage of the secondary winding is chosen at such a value as may be commutated satisfactorily, since it is short circuited on itself through its brushes.

The motor has the same characteristics as the direct current series motor, namely, maximum torque at starting, increasing torque with increasing current and decreasing speed, and comparatively constant efficiency through a wide range of speed. The maximum speed of the motor is limited only by the load and impressed voltage and has no relation to the synchronous speed.

Due to the reactance of the motor circuits, the power-factor at starting is low and will be with any alternating current motor; but in the repulsion motor a low power-factor does not mean small torque. On the contrary, the maximum torque occurs simultaneously with the lowest power-factor; that is, at starting. The power-factor of the repulsion motor rises very rapidly with the speed; it reaches a good value at one-third synchronous speed, and values near to 90 per cent. are obtained over a considerable range of speed. For this reason a large number of poles is not necessary and frequencies of 25, 40, and even 60 cycles may be employed.

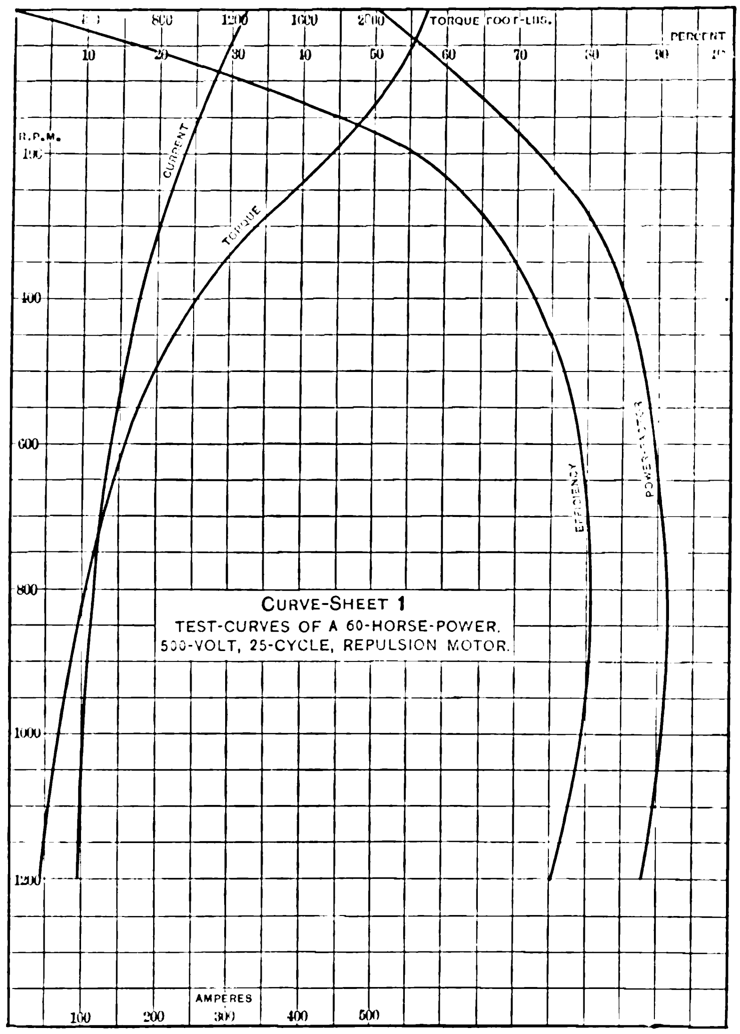
The rotating conductors of the secondary cutting the primary flux, generate a leading EMF., which causes a leading current to flow therein and gives the high power-factor of the motor. In the plain repulsion motor, this leading current never reaches a value great enough to compensate entirely for the magnetizing and other wattless currents at available speeds, but the phenomenon is utilized to obtain unity power-factor in the compensated type by the addition of a second circuit. The inherently good power-factor of the repulsion motor makes it possible to use larger clearance between field and armature than is permitted in induction motors, thus greatly increasing its value in railway work where comparatively large air-gaps are necessary.

The curves given are partly from test and partly from calculation of motors having air-gaps on a side of ⅛ inch and more. The air-gap of corresponding stationary induction motors would be .040 inch and more.

The efficiency, while not so good as in a direct-current motor, is yet very good, reaching values of from 80 to 85, including gear-loss for sizes ranging from 50 to 200 hp.

Commutation at normal speeds is inherently good, due to the revolving field. As the speed decreases, the current increases rapidly, producing a tendency to spark, but with the reduced voltage of starting the rush of current is limited to values within the range of good commutation, as in the direct-current motor.

At higher speeds, ranging above one-and-a-half times synchronism, the frequency of commutation becomes high and sparking appears.



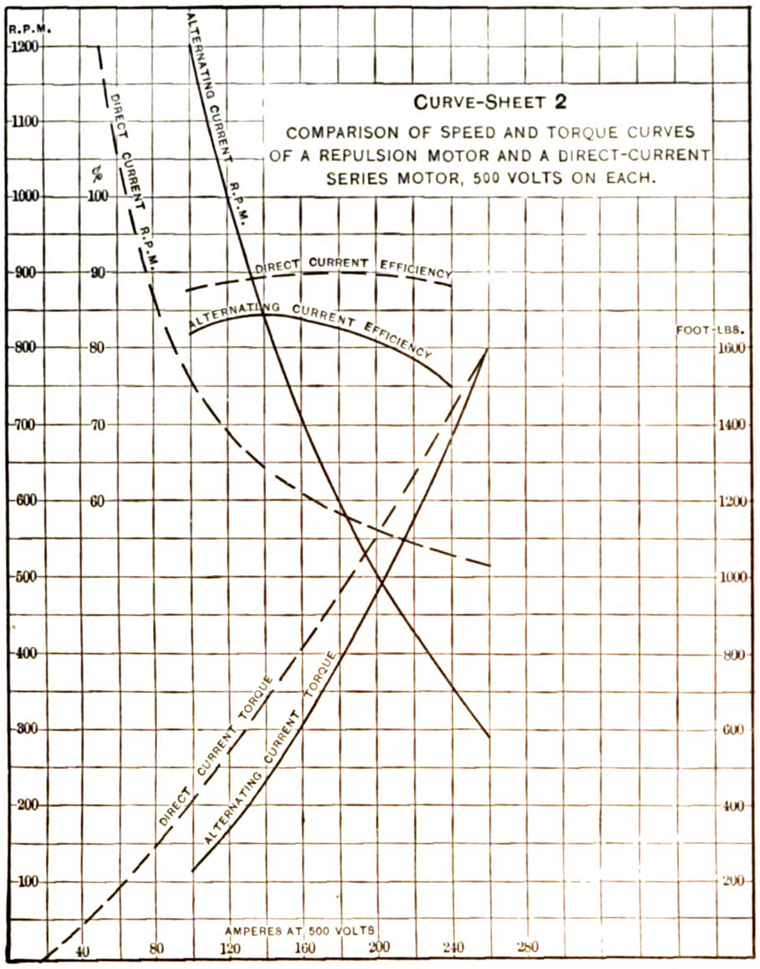
CURVE-SHEET 1
TEST-CURVES OF A 60-HORSE-POWER. 500-VOLT, 25-CYCLE, REPULSION MOTOR.

The motor of Curve-Sheet 1 will start with 75 per cent. of full voltage and twice full-load current with no trouble from sparking. As these curves are prepared upon a railway-motor basis and full-load current will produce a rise of 75 degrees C. after one hour's run the ability of the repulsion motor successfully to commutate over-loads is equal to that of the direct-current series motor, in fact, better, due to the short-circuited commutator, which makes flashing-over impossible.

Curve-Sheet 1 shows the characteristics of a repulsion motor plotted with

*Paper read at the 183d meeting of the American Institute of Electrical Engineers, New York, January 29, 1904.

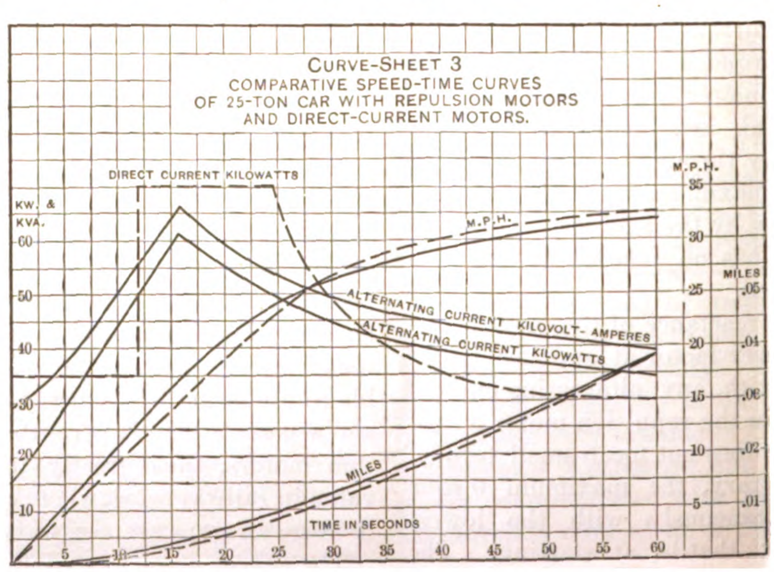
revolutions per minute as a base. The curves shown are taken from tests on a 60 hp., 25 cycle, 500-volt motor; they show the rapidly rising efficiency and



power-factor and the large torque at starting. The starting torque is 2,300 foot pounds, with an input of 325 amperes, and the normal torque during acceleration is 450 foot pounds at 750 revolutions and 125 amperes. Thus the starting torque is five times normal and the starting current 2.6 times normal, or the torque per ampere at starting is 1.92 times what it is at normal speed, should occasion demand the full starting capacity of the motor.

This gives an idea of the steep speed-characteristics of the motor, which are even better shown in Curve-Sheet 2. The full lines refer to a later type of repulsion motor and the broken lines to a standard direct-current series railway motor; these curves are plotted in the usual way with current as a base. This shows that the torque increases more rapidly with increasing current in the repulsion motor than in the series; and conversely that the speed of the repulsion motor increases more rapidly with decreasing current than in the series motor. Efficiency, including gear-loss, is given and is 84.5 per cent. at the maximum for the alternating-current motor. This motor was designed with the steep speed-characteristics for acceleration work, while the motor of Curve-Sheet 4 is designed for constant-speed running and has not such steep curves but better constants at light loads.

The characteristics show the repulsion motor to be admirably adapted for acceleration work, the efficiency of acceleration being higher than in direct-current work, due to the possibility of obtaining fractional E.M.F.'s with alternating cur-



rents without introducing the dead resistance losses of the direct-current system of control.

This is shown in the curves on Curve-Sheet 3, which gives the acceleration curves from a test of a 25-ton car equipped with two 60 hp. repulsion motors. The full lines indicate the repulsion motor characteristics and the broken lines those calculated for a direct-current equipment. The gearing is chosen for the same free running speed, 33 miles per hour, the same average acceleration, and the same distance covered in 60 seconds. For the direct-current motor the curve of kilowatts' input, miles per hour and miles traveled are given as calculated; and for the alternating-current motor the kilovolt-ampere input, kilowatt input, miles per hour and miles traveled, from test.

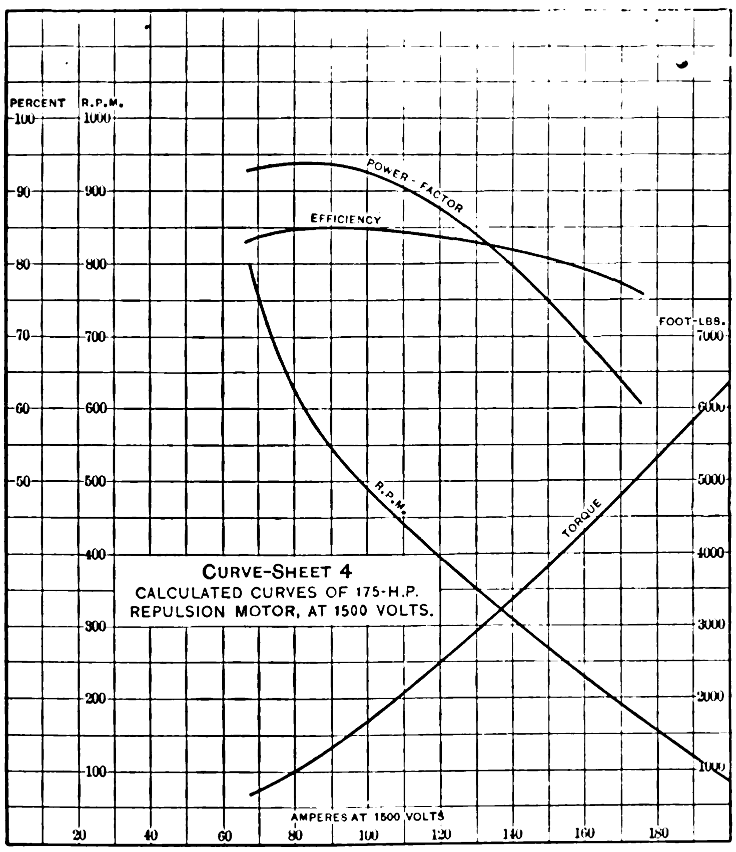
The repulsion motor remains on the controller only 16 seconds and the direct-current motor 25 seconds. The maximum power taken by the direct-current motor is 70 kw. and by the repulsion motor 61 kw. or 67 kilovolt-amperes. At the end of 25 seconds the total kw.-hour input in the two cases is .375 for the direct current and .30 for the alternating current. At the end of 60 seconds both cars have covered a distance of .039 mile and have reached practically the same speed of 32.5 miles per hour, the kw.-hour input being .72 for the direct current and .685 for the alternating current.

By comparing the areas of the kilowatt curves in the two cases the gain or rather the saving by the use of the alternating current is readily seen. It is also worthy of note that the volt-ampere input of the alternating-current motor is least at starting, that is, the line current is least. As this is the time at which the power-factor is lowest, it is seen that the effect of the low power-factor on the regulation of the system is much modified by the small value of the current. Curve-Sheet 4 shows the calculated characteristics of a 175 hp. railway repulsion motor having an air-gap of .15 inch and wound for 1,500 volts and 25 cycles. The

efficiency, including gear-loss, is 85 per cent. at the maximum and the power-factor is 93. Such a motor is designed for heavy, slow-speed locomotive work, which is probably one of the most promising fields for the alternating-current motor. It is readily seen how well it is adapted for freight haulage by the fact that the efficiency of 85 per cent. is attained at a speed as low as 500 revolutions, thus permitting a speed of 12 to 15 miles per hour with a good gear reduction.

Thus the repulsion motor is well adapted for acceleration work as well as for efficient running at light loads, and having good constants at low speeds is well adapted for freight haulage at low speeds.

The curves given in this paper all refer to the simple repulsion motor. There are many variations of the repulsion motor, more or less complicated, from which a better power-factor and even a better efficiency have been obtained in test. However, a description of these various schemes with their characteristics would require sufficient space to warrant a distinct paper and it is hoped to present such to the Institute at some future date.



CURVE-SHEET 4
CALCULATED CURVES OF 175-H.P. REPULSION MOTOR, AT 1500 VOLTS.

Discovery has been made in the northern part of Emery County, Utah, of an immense deposit of rock which, it is said, contains a large quantity of radium. The deposit of this rock is located on a ranch, and can be traced to the surface for 3,000 feet.

TESTING LARGE ALTERNATORS.*

BY W. E. BURNAND.

The tests mainly required on alternators are for ascertaining the efficiency, regulation on unity and lower power-factors and for heating under load. Two general methods appear to be available for making these tests, firstly, by the rather barbarous method of loading up the machine with resistances, choking coils, etc.; or, secondly, by more scientific methods which may be said to have had their commencement with Hopkinson, in which the machine under test and other apparatus connected with it are supplied only with the amount of power lost in the system. Unfortunately the second method, as hitherto practiced, seldom gives results strictly comparable with what will occur in actual use, and though it may be said to be scientific, if by science is meant measurement, it is hardly so if this is qualified by saying measurement of the thing you want to measure. The first method, however, is so cumbersome and expensive that in the case of really large alternators it becomes quite impracticable and the machine either has to go untested or some modification of the second class made, and the results that will occur in use with the machine deduced therefrom.

When two machines of equal capacity are available, they may be coupled together and the Hopkinson test pure and simple carried out, the power-factor of the load being varied as desired by manipulation of the field strengths.

As a rule, however, two machines are seldom available, and recourse must then be had to opposing half (approximately) of the armature to the other half, and circulating current through the windings in the manner described by Mordey, Behrend and others. But the methods I have seen described have always been open to some great objection, such as, when the armature is the rotating part, putting great, unbalanced strains on the machine, causing vibration which in some cases endangers the integrity of the machine, and also, in the majority of cases, the armature reaction, and consequently the core losses and regulation observed are entirely unlike what will occur in actual use, and, therefore, vitiate the results obtained as tests for regulation, efficiency or heating under full load conditions.

It seems to the writer that these objections can be overcome in a simple manner by the following methods: First, as to the unbalanced strains in the machine; the cause of this will be readily understood by reference to the diagrams. Fig. 1 represents an eight-pole alternator, con-

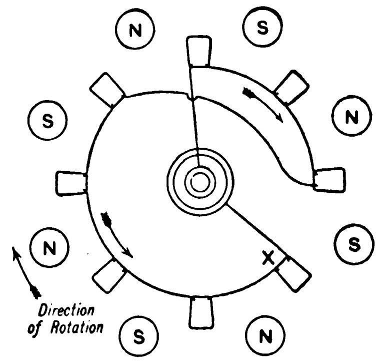


FIG. 1.

nected so that three coils oppose the other five. Connected thus, the five coils circulate a current round the armature against the E.M.F. of the three coils, the strength of which can be regulated by the field strength or by means of a rheostat in circuit. Thus half (approximately) of the armature will oppose the rotation of the machine, and the weaker half will help it, the difference in rotative effort plus friction having to be supplied from an external source. The arrows in Fig. 1 show the direction of this effort exerted by the two sides of the armature, from which it will be seen that both tend to force the armature in the same direction. If the armature is stationary, this is not usually of any great consequence, but if the armature is rotating, the effect is just the same as if a heavy weight were located at the point marked x, which naturally tends to put severe strains on the framework of

*From the "Electrician," London.

the machine. This could be balanced by a weight on the opposite side, the value of which could be calculated from the apparent horse power of the machine, the peripheral speed, diameter and power-factor, but a much better way would be to prevent these strains altogether, by dividing the armature circuit into quarters instead of halves, as shown in Fig. 2, coupling A and C in series, opposed to B and D. By this means the stresses, which are indicated in the figure by arrows, balance themselves round the circumference of the armature, leaving no unbalanced strains to be transmitted through the shaft to the framework of the machine.

Having got over this difficulty, there still remains that of armature reaction. The difficulty here results almost entirely from the great lag or low power-factor of the currents circulating round the armature, when the current is caused to circulate by a higher EMF. in one-half of the armature than in the other half. Thus the current in the coils is nearly at its maximum when they are directly opposite the pole pieces of the machine, whilst with a power-factor of unity the current is zero in this position, the conditions being reversed again in the midway position—i.e., the lagging currents are nearly zero here, whilst the current with unity of power-factor should be at its maximum. It is evident that this must have a great effect on any test for regulation or efficiency, the 1. power-factor having comparatively little influence on the poles, whilst with currents lagging nearly 90 degrees the coils on the weaker half, or the half in which the current flows against the induced EMF., have a powerful tendency to help the magnetic field, and on the stronger half a powerful demagnetizing tendency, thus giving rise to induced currents in the magnetic system, and also affecting the core losses of the machine. The mechanical strains also are not those met with in use—there is more tendency to vibration, and less of a straight pull or push backwards on the coils than is the case under load, when the current through the coils is at a maximum at the point midway between the poles—hence in a position of maximum effect.

The effect this has with a current lagging about 90 degrees is that for every time a coil passes a pole piece, it is first subjected to a force in a backward direction till it gets opposite the pole, and then in a forward direction till in the midway position. Thus there is a severe racking strain backwards and forward at the rate of four times the frequency of the machine, whereas with a current in phase with the EMF. the strain is always in one direction, either backward or forward, considered with respect to the direction of rotation, according as the current circulates with or against the EMF.

The method devised by the writer to overcome these difficulties is to connect up the armature as in Fig. 2, the number

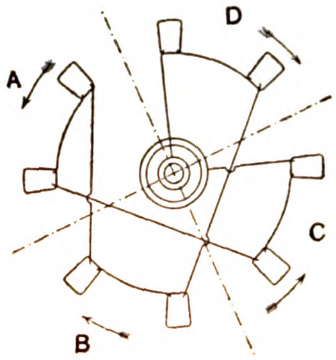

Fig. 2.

of coils in the quarters A and C being equal to that of B and D, so that the EMF. of two quarters opposes and balances the EMF. of the other two quarters, and to circulate an alternating current through the armature from an external source of the same frequency as the machine under test, and whose phase with respect to this machine may be readily adjusted. This external source may consist of a small alternator with the same number of poles as the machine under test and coupled to the same shaft, or it may be a machine of a different number of poles, driven from the shaft through chain or spur gearing. This machine, of course, may be in circuit with the large one, either direct or through a transformer, and only need be of a size capable of supplying the electrical losses in the large generator and con-

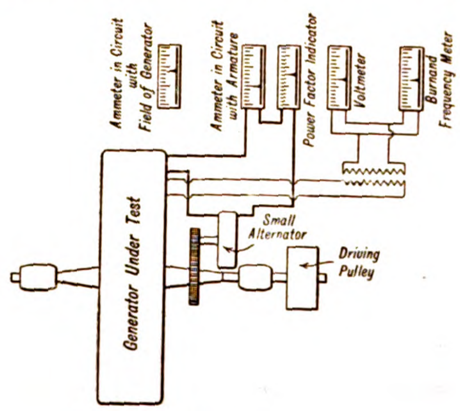

Fig. 3.

nections. By this arrangement practically all the effects of full load can be simulated in a manner to get practically reliable results. The auxiliary alternator can be so driven with relation to the machine under test as to circulate a current of leading, lagging or any desired power-factor.

The heating can, therefore, be determined for any of these conditions, and the regulation likewise. The efficiency can be determined from the balance of power required to drive the machine at its working speed with full load current circulating through the armature, at any desired power-factor, after subtracting the power lost in the outside connections, the auxiliary alternator and the gearing driving it, all of which can be easily determined with an accuracy near enough to give materially correct results for the machine under test.

Fig. 3 shows the manner of testing the regulation of the machine, the voltmeter and power-factor indicator being in connection with the half of the machine in which the current flows in the direction of the EMF., the frequency meter being connected at any convenient place, say, in parallel with the voltmeter. A reading is first taken with no current passing through the armature; afterwards a reading is taken with full-load current passing, the power-factor of which can be regulated by causing the auxiliary alternator to lead, lag, or keep in phase with the EMF. of the machine under test, the amperes being readily adjusted by a rheostat in the field of the small alternator.

Assuming the speed kept constant, the difference in the voltmeter readings gives the drop in half the armature. If the machine is designed to work with the armature coils all in series, the regulation is, of course, double this value; if the two halves are to be in parallel the regulation is direct as given by the voltmeter readings. Should it not be possible to get the speed quite the same as when unloaded, the effect of this can be calculated from the difference in frequency, the EMF. being proportional to this at constant excitation.

A variation of this method might be to have a voltmeter on each half of the armature, the difference in the reading with full-load current passing giving the regulation, but the first method is probably preferable for a generator, as the armature reactions in the half referred to more nearly approach those of practice than is the case in the other half of the machine, in which the current circulates against the EMF. as in a motor.

It would not do to take the ratio of the voltage required to circulate full-load current through the machine to the voltage of the machine under test as a measure of the regulation of the machine, since, as a rule, the EMF. of the auxiliary machine will not be in phase with the EMF. of the machine under test. As a somewhat exaggerated example might be cited the case of a machine requiring an EMF. in quadrature with its own—say of half its own value—to circulate full-load current through it, the current to be in phase

with the EMF. of the machine under test. The regulation in this case, instead of being 50 per cent., is actually about 10 per cent., as is readily apparent when attention is paid to the vector phase relations of the two EMF.'s and current.

ELECTRICAL STATION PRACTICE.

ARTICLE XXIII.

BY W. H. RADCLIFFE.

Electrical measuring instruments, owing to the nature of their construction and the conditions under which they must necessarily be used, are subject to variations in accuracy. This feature is an annoying one on account of the difficulty of detecting it; a meter may, as far as appearances go, be in excellent working order and yet give readings which are not to be relied upon.

Measuring instruments constructed for use on direct current circuits often suffer in this respect owing to a weakening of the permanent magnet used to establish a field for the movable fine wire coil, or again their readings may be inaccurate on account of the pointer being bent, and still another cause is the aging of the spiral springs attached to the top and bottom of the movable coil which renders them less capable of exerting the necessary tension. The last two mentioned defects are as common in alternating current instruments as in direct current instruments and produce the same inaccuracies in each. Owing to the difficulty previously mentioned of readily detecting a trouble of this nature, meters are often kept in service when their indications are practically worthless. Of course, in some instances in station practice where only approximate readings are desired, meters having inaccuracies of 3 or even 5 per cent. may be used. By "an inaccuracy of 3 or 5 per cent." is meant that the deflection of the pointer will be higher or lower than the exact value by an amount proportional to an error of 3 or 5 divisions in every 100 divisions; thus, a voltmeter showing a deflection of 103 volts across a circuit the exact pressure of which was 100 volts would be said to have an inaccuracy of 3 per cent. On the other hand, if it indicate but 97 volts, its inaccuracy would also be 3 per cent. For measurements of precision, or for observations in any class of station work upon which much confidence is to be placed or on which there is much at stake, instruments having inaccuracies as large as 3 or 5 per cent. should obviously not be used. Ridiculous as it may appear, the average station attendant may frequently be seen straining his eyes to read to tenths of a division on the scale of a meter which, if subjected to test, would show an inaccuracy of over 2 per cent.

To guard against such inconsistency, it is frequently necessary to compare the meters in use with standards. By "standards" are meant meters which are comparatively new and which have been the least exposed to harm or injury. The comparison is made in the case of a voltmeter by connecting it in multiple with a standard voltmeter across an adjustable resistance, which in turn is connected in the supply circuit. By varying this resistance the drop in pressure across it is altered and a means is thereby afforded of obtaining different readings on the voltmeters without changing their positions in circuit. Since the meter undergoing test is connected across the same part of the resistance as the standard meter, it is subjected to the same conditions and should if correct give the same deflections as those on the standard meter. It order to obtain the best results there should be one man at each meter so that simultaneous readings may be taken on both instruments, and the man at the standard meter should have control of the adjustable resistance.

Each meter should be checked or calibrated at five or six approximately equidistant points over its scale; the adjustable resistance being varied each time to give a deflection on the standard meter of an even number of divisions and the deflection on the other meter recorded at whatever it may be. Having obtained the necessary readings, the calculation of the constant or multiplying factor of the meter undergoing test is next in order. This may best be shown by taking an actual case in which a 150-scale voltmeter is being tested to determine its accuracy. The data and calculations are as follows:

Readings on Standard Meter.	Readings on Meter Tested.	Constant.
150	149.2	150 ÷ 149.2 = 1.005
125	125.0	125 ÷ 125.0 = 1,000
100	98.9	100 ÷ 98.9 = 1.011
75	73.6	75 ÷ 73.6 = 1.019
50	50.0	50 ÷ 50.0 = 1.00
25	24.8	25 ÷ 24.8 = 1.008
		6.043

Average constant for six readings, 6.043 ÷ 6 = 1.007.

It may be stated in general that before taking the readings for this test the zero position of the pointer on the meter tested should be noted, and if it be more than two-tenths of a division off the zero mark the case of the meter should be removed and the pointer straightened. Furthermore, it will be noticed from the readings here recorded that the test is started at the high reading end of the scale; this is done in order that the pointer may gradually be brought up to this spot, by slowly cutting out of circuit the adjustable resistance, and thus show whether or not the pointer has a tendency to stick at any part of the scale. If the meter seems to be defective in this respect, it should be remedied either by bending the pointer or scale, or by renewing one or both of the jewels, before the comparison with the standard is commenced.

It is obvious from the readings recorded for our 150-scale voltmeter, that as compared with the corresponding deflections of the standard, the former are a trifle low. In order to determine for each observation how much too low they are, it is necessary to divide each reading on the standard by the corresponding reading on the meter tested. The result is the amount by which a deflection of this size on the meter tested must be multiplied by in order to obtain the exact reading. This multiplier is called a constant, and as shown a constant is determined for each of the six observations. The average constant for the six readings is then found, and this is taken as the constant for the meter as a whole; that is, whenever this 150-scale voltmeter is used, each reading taken thereon must be multiplied by 1.007 in order to correct for its inaccuracy. The most convenient and systematic way of registering the constant of a meter is to write it, together with the number of the meter and the date of its calibration, in ink on a cardboard tag and loop the same by means of a string to the handle or some other convenient part of the meter. The tag may then be readily changed at the next test, as a new one will probably have to be made out when the meter is again calibrated owing to a change in the value of its constant.

The complete calibration of a two-scale voltmeter does not necessitate that the readings on both scales be checked with standards as might be supposed, for since the resistance corresponding to the one scale is always some multiple of the resistance of the other, the constants of the two scales are proportional. Suppose we let S = the reading at the end of the high scale of the voltmeter; s = the reading at the end of the low scale of the voltmeter; R = the resistance in the meter corresponding to the high scale; r the resistance in the meter corresponding to the low scale; K = the constant for the high scale, and k = the constant for the low scale. Then

$$\frac{S \times K}{R} = \frac{s \times k}{r},$$

from which $k = \frac{S K r}{s R}$. That is to say if the respective resistances corresponding to the two scales be known, and the constant of the high scale be determined by comparison with a standard, then by aid of these known values and the maximum readings on the two scales, the constant of the low scale, may be calculated. It is also possible to calculate the constant of the high scale if the constant of the low scale be known, together with the values of the resistances corresponding to the two scales, for from the equation previously given, $K = \frac{R s k}{r S}$.

The calibration of an ammeter for determining its constant should be conducted along the same lines as previously described for a voltmeter. The connection of the ammeter in circuit, however, would be different in that it would be joined in series with the standard ammeter and the adjustable resistance, instead of being wired in multiple with them.

If a voltmeter or ammeter upon being tested shows it to have an error of more than 1½ per cent., the use of a constant is not sufficiently accurate. It will be remembered that in the determination of the constant of a meter the average of six constants was taken. When the inaccuracy of the meter is not great this average value of the constant is sufficiently exact to be applied to all readings that may be taken on the instrument, but when the readings on the meter differ considerably from those on the standard it is advisable to construct a curve the abscissæ of which represent the values of the readings on the standard meter, and the ordinates of which represent the values of the readings on the meter tested. With this curve at hand, any measurement afterward taken on the meter may at once be corrected by locating a point on the curve directly opposite this reading as found on the vertical scale of ordinates, and then noting the reading on the horizontal scale of abscissæ directly below this point on the curve. The construction of a curve is recommended in place of a constant when the inaccuracy of a meter is 1½ per cent. or greater. The same number of observations as used for calculating a constant will be sufficient for determining the course of the curve. The test is therefore conducted in precisely the same manner as already explained. Usually, it is possible from the readings obtained in a calibration test to tell at a glance whether the inaccuracy of a given meter is greater or less than 1½ per cent.; if, however, there is any doubt in the matter, the constant should be calculated and the choice between this constant and a curve governed accordingly.

If the calibration of a meter shows an inaccuracy of 3 or 4 per cent., it is not advisable to use even a curve, unless as previously stated the meter is to be used for approximate measurements only.

The usual remedies to apply to a voltmeter in this condition, if it is afterward to be used for accurate work, consists in strengthening the permanent magnet, straightening the pointer, varying the tension of the spiral springs, renewing the jewels in the bearings, or altering the value of the high resistance contained within the case. Although these remedies are more or less simple and readily applied, it may be well to call attention to at least two of them, the strengthening of the permanent magnet and the altering of the value of the high resistance contained within the case. In order to strengthen the permanent magnet it is necessary to detach it from the base of the meter, wrap around it several turns of insulated wire, and pass through this wire for a short time 3 or 4 amperes of direct current in such a direction as to reinforce the magnetism the magnet possesses. In order to alter the value of the high resistance of the voltmeter it is necessary to first obtain the constant of the meter so as to know how many per cent. high or low it is on the average. The resistance in ohms of the voltmeter as a whole must then be measured, and a certain length of wire whose resistance in ohms is the aforementioned per cent. of the original resistance, must be either added to or taken from the resistance coil in the meter, depending upon whether its pointer gives deflections which are too high or too low. After applying any of these remedies, it is of course necessary to again calibrate the meter and give it a constant or curve before putting it in service.

The remedies to apply in the case of an ammeter which is 3 or 4 per cent. in error consists in straightening the pointer, varying the tension of the spiral springs, renewing the jewels in the bearings, and in the case of a direct current ammeter strengthening the permanent magnet and changing the number of auxiliary circuits between the two copper plates. In applying the last mentioned remedy, the number of the auxiliary circuits must be increased if the deflections are too high, and decreased if the deflections are too low.

The calibration of a portable wattmeter is accomplished with direct current of constant value which is passed through the series winding by connecting the source thereof with the current terminals. A direct current voltage which may be varied throughout the range of the wattmeter is also applied to the instrument between the middle and right-hand pressure terminals, the wiring in the meter between these terminals being such that its differential winding is then cut out of circuit. The method of procedure consists in comparing the deflections on the wattmeter at five or six approximately equidistant points over its scale with the corresponding products of volts and amperes used to obtain them. The changes in the wattmeter deflections are effected by merely varying the voltage, the value of the current being maintained constant at a value which represents the full current capacity of the meter.

The checking up of a recording wattmeter may conveniently be done by noting the deflections at short intervals on an ammeter connected in circuit, and also the reading on the dial of the recording wattmeter during this period. If this test is continued for an appreciable time, the product of the pressure in volts, the current in amperes, and the time in hours, should equal the number of watt-hours recorded on the counters of the dial.

In an alternating current meter one of the most frequent causes of error is the deterioration of its insulation which permits the working parts of the instrument coming in contact with the surrounding metal case. The most convenient method of testing a meter defective in this respect consists in connecting its terminals in series with a voltmeter in good working order and a source of voltage. Instead of connecting both terminals of the defective meter in circuit, however, but one terminal is thus connected, while the lead which would naturally be joined to the remaining terminal of this meter is brought in contact with its metal case. If there is a ground or contact between the working parts and the case, there will be a deflection of the pointer on the voltmeter. Suppose it be desired to have the insulation resistance of the defective meter measure R ohms. Then if the voltage at hand be V volts, and the resistance of the voltmeter in use be r ohms, the current, C, passing through the grounded part of the defective meter is $C = \frac{V}{R + r}$.

The pressure, E, necessary to force this current from the metal case of the defective meter to its working parts is C r, and as the values of both C and r are known, the value of E may be determined. If, therefore, the voltmeter in use shows a

deflection not lower than E volts under the conditions mentioned, the insulation resistance of the defective meter will be at least R ohms, and the fault evidently lies elsewhere. On the other hand, a deflection of less than E volts on the voltmeter in use will indicate a low insulation resistance in the meter tested, and an inspection of the interior wiring of this instrument will probably reveal the cause of the trouble.

RADIUM.*

BY PROF. R. A. MILLIKEN.

(*Concluded from page 67.*)

The study of the cathode rays has sounded the death knell of the indivisible atom of our earlier chemistry, and gave the first suggestions of the discoveries which were soon to follow, which showed that under some circumstances the atoms of chemistry do disintegrate into small parts.

It was first thought the X-rays were cathode rays after they got out through the walls of the tube, but they proved not to be so, because the X-rays are not deflected in the slightest degree by a magnet, not deflected by an electrostatic field, and do not impart negative charges to objects on which they strike; and they are supposed to be ethereal pulsations of the same nature as light, whereas cathode rays are streams of projected particles shot off from a negative electrode. At first the rays emitted by uranium were thought to be a form of X-rays. But it was found that rays from uranium were deflected as cathode rays, and also the rays would impart negative charges upon any objects upon which they struck; so we say that radio-active substances are always spontaneously emitting cathode rays.

In 1899 it was discovered that cathode rays are not the only particles to be shot off by radio-active substances. There are other particles which differ from the cathode particles, first in penetrating power, and second, these penetrating rays are deflected by the magnetic field. These are the cathode particles, whereas the non-penetrating rays will not produce photographs and are not deflected—they are not the same as cathode ray particles. The non-penetrating rays have been called the Alpha rays and the cathode rays the Beta rays. Prof. Rutherford showed that the Alpha rays, with a powerful magnet, are deflected to the right, while the Beta rays are deflected to the left. The Alpha rays are deflected not only by a magnet but by an electric charge, though in every case they were deflected much less than the Beta rays, but always in the direction in which they would be deflected if they consisted of positively charged particles.

These experiments have been confirmed, and we can say with positiveness that we know that the Beta rays consist of streams of negatively charged particles, and the Alpha rays of positively charged particles, but from the amount of deflection of the Alpha rays a very surprising result is obtained, namely, that the Alpha rays instead of being composed of minute particles of the size of 1-1000 of an atom, are composed of particles twice as big as a hydrogen atom. Further, despite the great mass they still have enormous velocity. The cathode particles have a velocity of only 20,000 to 30,000 miles a second, but those projected from the radium, the Beta rays, have a velocity which sometimes is as high as 175,000 miles a second. The Alpha particles, the heavy particles, do not have as much velocity, but they have as high velocity as 20,000 miles a second.

These differences in size and velocity explain the properties of both the Alpha and Beta rays, and this discovery threw a flood of light upon the difference in properties of the two kinds of rays.

There is a third type of radiation associated with radio-active substances; the Gamma rays, which are more penetrating still, and arise out of some ethereal disturbances set up by these impacts of particles upon other particles. However, so far as our considerations of energy are concerned, we can neglect altogether these Gamma rays.

Radio-active substances then are spontaneously shooting off with enormous velocity these three kinds of particles, and this has been illustrated by the use of Prof. Cook's spintheroscope. This radio-activity is not due to any ordinary molecular change, but is absolutely independent of all chemical changes as it is of all physical changes. You can reduce a bit of uranium to the lowest temperature obtainable, or raise it to the highest temperature possible, and the rate of radiation will not vary. Radio-activity is something wholly outside the range of ordinary molecular forces. It must be something that has to do with the atom, and the radio-active substance itself, and not with simply the shifting of atoms about inside of the molecule, such as takes place in ordinary chemical changes.

This is the first time that any store of subatomic energy has been tapped by man; although in the case of the cathode rays we had the suggestion that it was possible to break up the atoms of ordinary substances under some conditions. We see, therefore, that we have a radio-active change, whatever it is, consisting in something going on in the nature of the atom of the radio-active substance.

Chemical and other investigations support the conclusion that the radio-activity consists in a slow disintegration of the atom of the radio-active substance. The first step in radio-activity consists in the projection of one or more of these Alpha particles from the atom of the radio-active body.

The three radio-active substances that are known, the only ones that are certainly known to be elements, namely, uranium, thorium and radium, are the three heaviest atoms known. The atomic weight of uranium is 240, thorium 231, radium 225. Now, according to our ordinary mechanical theory of heat, the atoms of all substances are in rapid rotation and vibration. It appears, therefore, that the heavier atoms sometimes become unstable and fly apart. There is no reason why an atom should not disintegrate and fly apart any more than why a stellar system should not explode.

Experiments show that under some circumstances certain of the elements become unstable, and because of their motions project off from themselves a part of their mass, that is, split up into smaller elements. Probably if any other radio-active substances are discovered they will be substances of very high atomic weight. Gold, bismuth and lead have high atomic weights. Whether these ever become unstable is uncertain, but so far as any test of radio-activity is concerned they are not. These are the only three which we have yet discovered which are undergoing this sort of a change.

Now with this picture of the nature of radio-activity in mind, Prof. Rutherford about a year and a half ago, made one of the most remarkable predictions ever made in the history of science. Knowing that helium, which is the element first discovered in the sun by a new line in the spectrum of the sun, and which was a few years ago discovered for the first time in the earth, and bearing in mind that helium happens to be found in nature only in connection with these radio-active elements, namely, with uranium, thorium and radium, he predicted that helium would ultimately be found to be one of the products of radio-active disintegration. When a year ago he found that these Alpha particles, which are projected by all radio-active substances, have the same mass as the helium atom, his prediction

*Lecture delivered at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

began to be more probable, and only last July Prof. Ramsay in London actually took the emanations from radium and examined them under the spectroscope and at the end of five days saw the spectrum of helium grow out of the emanations from radium, which seemed to prove exactly the thing which Prof. Rutherford had predicted, namely, that the element helium is a product of the disintegration of radio-active elements.

Now I will have one word to say on the possible life of radium, and then another word on the possible transmutation of the elements.

Radium and all radio-active substances are continually projecting particles from themselves, and they must therefore lose weight. If their atoms are becoming unstable and breaking up, of course the number of atoms that can thus become broken up is limited from there being only a certain number of atoms present, and in time all these living substances will lose weight and will lose activity. So far, no one has discovered that radio-active substances either lose weight or lose activity. They appear to be going on at the same rate as ever; but we can easily calculate from the knowledge of the mass of the projected particles and from a knowledge of the amount of energy that is given off by radium per second, namely, the fact that radium is continually giving off heat and light, that it maintains a temperature of one to two degrees higher than the temperature of its surroundings, which seems a most wonderful fact, but as soon as you have this picture of the nature of radio-activity in mind you see an explanation, because if the molecules of radio-active substances are continually projecting with these enormous velocities particles from themselves, then on account of this tremendous internal bombardment which the radium is subjected to, you can see why the temperature of radium should be held up above the surrounding temperature, and why it should radiate continually 100 calories of heat per gram per hour.

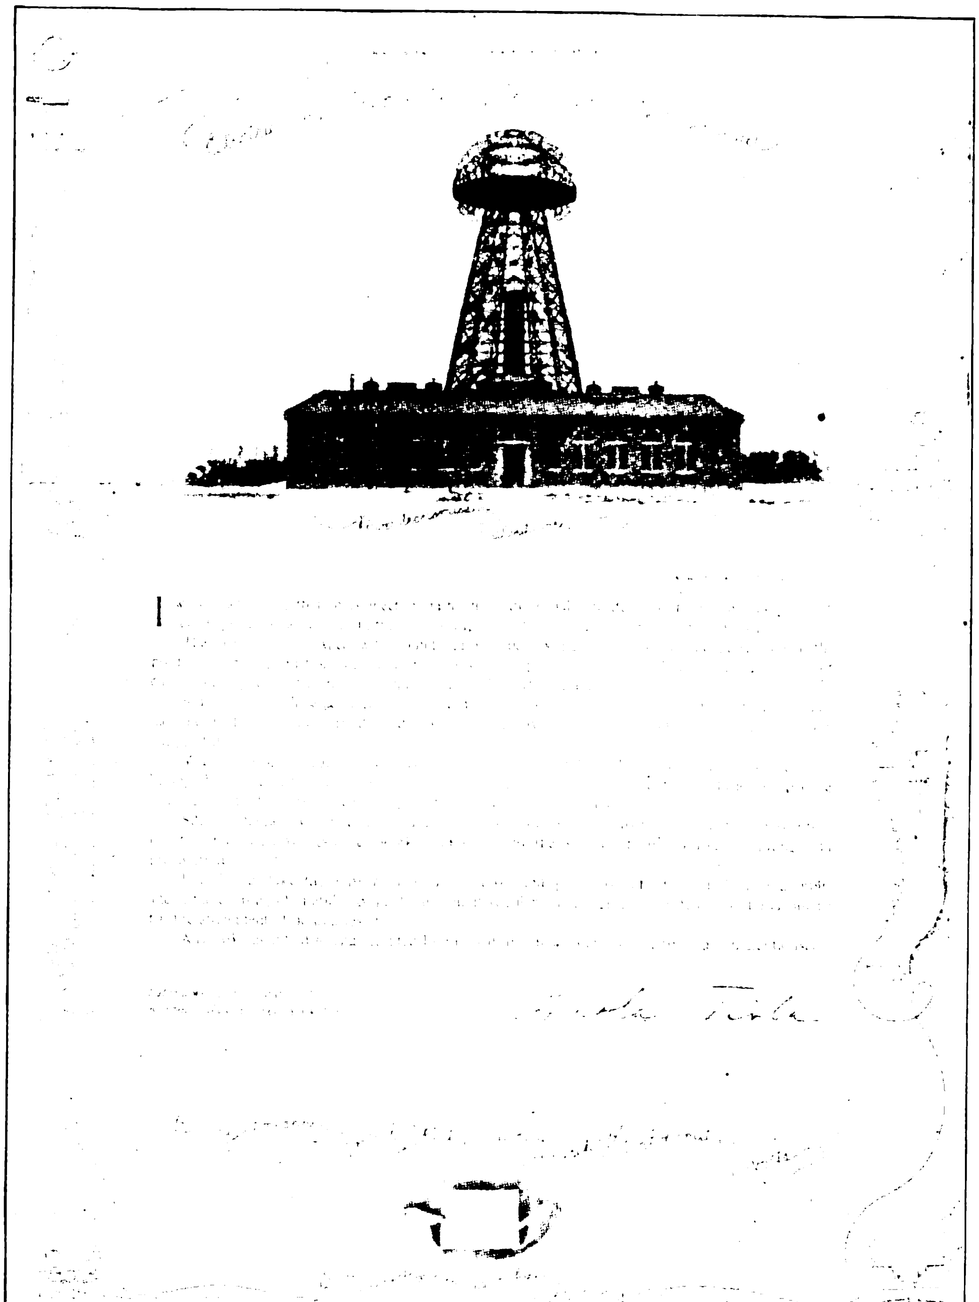
From the knowledge of the amount of energy given off from radium per second and the knowledge of the mass of the projected particles and the velocity of those particles, we know what their kinetic energy is, and we can calculate exactly how many particles are shot off per second, and we can tell the rate at which radium is losing weight and activity. On the presumption that radium all disintegrates completely into helium I have calculated the maximum possible life of helium to be 80,000 years; that is, a gram of radium will cease to be radium in a period of time not later than 80,000 years. Uranium and thorium will last a million times as long.

Now, if radium can only last 80,000 years, and if the earth has been in existence millions of years, how does it happen that radium is on the earth at present?

We see from these experiments that it looks as though the promises of the alchemists were in certain instances realized, that is, as though certain of the elements, that is these heavy ones, were spontaneously degenerating into other elements, radium into helium, uranium into helium, and solium into helium, etc., indicating a possible transmutation of the elements under some circumstances. Now, is it ever possible that you can build up from the simpler atom to the more complex atom? Is there any process in the atomic world which does for the atoms what the life process does for the molecules—which takes the simpler elements and builds them up into more complex elements? I should be rash to attempt to answer that in the affirmative, and yet the fact that radium now exists on the earth when according to our calculations it cannot live more than 80,000 years, seems to indicate that it must be produced, that is, that there are processes going on which are transmuting in both directions among atoms, just as there are among the molecules.

Now, the amount of energy which is given off from the disintegration from one gram of any radio-active substance, is a million times as much as is given off from the disintegration of any chemical compound. We have had revealed, there-

MR. TESLA'S LATEST MOVE.



fore, stores of sub-atomic energy that we never dreamed of before. The question that will arise is, is there any way in which this sub-atomic energy may be ever turned to practical use for the supply of man's economic needs? There does not seem to be any probability that it can be, because the only elements that we know of now that are disengaging that energy, are doing it at such a minute rate that unless there is some way of accelerating the process there is no probability that we can ever utilize this discovery of these stores which must be immense, of sub-atomic energy, in turning the wheels of industry.

Radium may be of some use in medicine, although it is uncertain what its place will be. It does not look now as though it will be of any economic value, but of course it is not right to say things cannot be when you remember what has been done. However, if no practical use is found for radium, yet the greatest end possible has been served, for radio-activity has extended man's knowledge of the way in which nature works and of the constitution of nature.

The Institute's Annual Dinner.

The annual dinner of the American Institute of Electrical Engineers will be held to-morrow evening, February 11, in the ball-room of the Waldorf-Astoria, 34th street and Fifth avenue. Mr. T. Commerford Martin will be toastmaster and the following gentlemen have consented to speak: Mr. B. J. Arnold, Mr. Samuel Insull, Mr. Charles L. Edgar, Dr. A. E. Kennelly, Prof. Cyrus F. Brackett and Mr. J. B. McCall.

The 25th anniversary of the introduction of the incandescent electric light and the 57th anniversary of the birth of Thos. A. Edison will be celebrated at the dinner. Mr. Edison will be the guest of honor.

The deed of trust of the Edison Medal Association will be presented at the dinner.

Branch Office Managers in Annual Conference.

The annual conference of the branch office managers of the Standard Underground Cable Company with the general sales, the manufacturing, the construction and the executive departments of the company, was recently held in the general offices of the company in the Westinghouse Building, Pittsburg, the session covering three days. The report of each manager for the year 1903 and the business prospects for the year 1904 was presented and discussed, together with ways and means for rendering more efficient service in every department to the customers of the company, who now number considerably over 1,000.

A pleasant social feature of the occasion was a theater party given by Mr. J. W. Marsh, vice-president and general manager of the company, to the visiting managers.

The branch office managers attending the meeting were Mr. Chas. J. Marsh and Mr. George L. Wiley from the New York office, Mr. Frank Clark Cosby from the Boston office, Mr. T. E. Hughes from the Philadelphia office, and Messrs. J. R. Wiley and E. J. Pietzcker from the Chicago office.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 2, 1904.

Electric Railways and Appliances.

750,818. Trolley Harp or Fork. Fred P. Crockett and Osro P. Johnson, Kalamazoo, Mich. Filed April 4 1903.

750,825. Automatic Trolley-Line Reel. Charles F. Davy, Mohawk, N. Y., assignor of one-half to H. M. & M. M. Scofield, same place. Filed March 19, 1903.

750,880. Means for Anchoring the Combined Third and Traction Rail of Electric Railways. John H. Morgan, Chicago, Ill. Filed July 6, 1903.

750,991. Railroad Signaling Device. Joseph R. Marchesseault, Meriden, Conn. Filed Nov. 13, 1902.

751,021. Automatic Signaling System for Electric Railways. Harry B. Snell, Cement City, Mich., assignor to the Snell Electric Signal Company. Filed April 25, 1903.

751,048. Signal System for Electric Railways. Charles P. Breeze, Norfolk, Va., and Adoniram J. Wilson, Westfield, N. J., assignors to the Hall Signal Company. Filed May 5, 1902.

751,175. Third Rail for Electric Railways. Lloyd G. Johnstone, New York City, assignor of one-half to Jacob Ahrens, same place. Filed Oct. 10, 1903.

751,298. Trolley. James Kel'y, Pittsburg, Pa., assignor of one-third to James Croak, same place. Filed July 11, 1903.

Electric Lights and Appliances.

750,894. Electric-Arc Lamp. Joseph A. Rignon, Berlin, Germany. Filed April 11, 1902.

751,013. Signal Device for Searchlight Projectors. Robert H. Read, Schenectady, N. Y., assignor to the Genera' Electric Company. Filed Aug. 2, 1901.

751,025. Electric-Arc Lamp. George E. Stevens and Walter C. Fish, Lynn, Mass., assignors to the General Electric Company. Filed June 14, 1902.

751,028. Means for Extinguishing Electric Arcs. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Aug. 1, 1902.

751,321. Electric-Light Fixture. John J. Miller, Pittsburg, Pa., assignor of one-half to Henry Braun, Allegheny, Pa. Filed May 21, 1903.

751,411-12-13-14. System of Lighting by Gas or Vapor Electric Lamps. Henry N. Potter, New Rochelle, N. Y., assignor to the Cooper-Hewitt Electric Company. Original application filed May 28, 1901. Divided and last application filed April 30, 1903.

Electrical Machinery and Apparatus.

750,938. Alternating-Current Wattmeter. Charles A. Brown, Chicago, Ill. Filed July 24, 1900. Renewed June 24, 1903.

750,939. Process of Measuring Watts in Alternating-Current Circuits. Charles A. Brown, Chicago, Ill. Filed Nov. 19, 1900.

750,940. Alternating-Current Motor, Charles A. Brown, Chicago, Ill. Filed July 13, 1903.

750,947. Electric Controller. Frank E. Case, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 16, 1901.

750,948. Demand-Discount Meter. Frank P. Cox, Lynn, Mass., assignor to the General Electric Compauy. Filed Aug. 15, 1902.

750,971. Switch for Series Arc-Circuits. Caryl D. Haskins, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 22, 1902.

750,972. Means for Controlling Electric Boosters. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 31, 1900.

750,980. Field-Coil Structure. Charles H. Kaler, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 5, 1902.

750,993. Electric Switch. George Monson, Schenectady, N. Y., assignor to the General Electric Company. Filed July 25, 1901.

750,995. Power-Transmission Mechanism. Emil A. Nelson, Cleveland, O. Filed Sept. 2, 1902.

751,003. Controller-Casing. Charles L. Perry, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 26, 1900.

751,007. Telltale-Register. William H. Pratt and Alexander J. R. Flego, Lynn, Mass., assignors to the General Electric Company. Filed June 24, 1901.

751,012. Fuse-Box. Robert H. Read, Schenectady, N.Y., assignor to the General Electric Company. Filed April 1, 1901.

751,015. Electrical Measuring Instrument. Lewis T. Robinson, Schenectady, N. Y., assignor to the General Electric Company. Filed Feb. 10, 1902.

751,016. System of Electrical Distribution. Nelson W. Rogers, Mount Vernon, N. Y., assignor to the Cooper Hewitt Electric Company. Filed Feb. 9, 1903.

751,084. Electric Switch. Ernest A. Lowe, Plainfield N. J. Filed Jan. 17, 1902.

751,120. Electrical Controller and Brake-Operating Device. Walter W. Tice, Rahway, N. J. Filed Apri 7, 1903.

751,174. Electric Switch. William F. Irish, East Orange N. J. Filed July 23, 1902.

751,191. Electric Motor. Hiram P. Maxim, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed March 12, 1903.

751,227. Electric Cut-Out. William H. Verner, Pitts burg, Pa. Filed Aug. 28, 1902.

751,362. Thermostat. John L. Ward, Ord, Neb. Filed July 8, 1903.

Telephones and Telephone Apparatus

750,793. Selective Signaling System. Garrison Babcock, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed July 17, 1903.

750,835. Telephone-Transmitter. Ernest B. Fahnestock, New York City. Filed Dec. 2, 1901.

750,845. Switching Apparatus. John S. Goldberg, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed Nov. 26, 1902.

750,953. Plug-Ejecting Jack for Telephone-Switchboards. Robert G. Dunfee, Fostoria, O. Filed June 6, 1902. Renewed Dec. 15, 1903.

751,081. Coin-Controlled Telephone Apparatus. Sherwood J. Larned, Chicago, Ill., assignor to the American Telephone & Telegraph Company. Filed Dec. 3, 1903.

751,103. Telephonic Call-Instrument. John D. Peachey East Orange, N. J. Filed Jan. 6, 1903.

751,344. Telephone-Receiver. Lewis Sands and Chas. C. Cadden, Cleveland, O., assignors to the Williams-Abbott Electric Company. Filed March 6 1903.

Miscellaneous.

750,807. Telegraph Apparatus. John E. Carney, Montgomery, Ala. Filed Feb. 24, 1903.

750,871. Exciting Compound for Batteries. Adolf J. Marschall, Little Falls, N. Y. Filed May 21, 1903.

750,876. Electric Plant for Charging Storage Batteries Joseph B. Meriam and Mark B. Crist, Cleveland, O., assignors to the Meriam-Abbott Company, same place. Filed July 25, 1902.

750,892. Gas or Vapor Electric Apparatus. Max von Recklinghausen, New York City, assignor to the Cooper-Hewitt Electric Company. Filed Oct. 17, 1903.

751,031. Massaging Implement. Julius B. Wantz, Chicago, Ill., assignor to the Victor Electric Company. Filed Oct. 15, 1903.

751,046. Plate for Storage Batteries. Joseph Bijur, New York City. Filed March 31, 1902.

751,071. Signaling Apparatus. Edwin L. Grauel, Rochester, N. Y., assignor to the National Telegraphone Company, same place. Filed March 19, 1903.

751,100. Electromagnetic Ore Separator. Ellen M. Oviatt and Alexander Dean, Denver, Col. Filed May 3, 1901.

751,150. Electromagnetic Ore Separator. Alexander Dean, Denver, Col. Filed Dec. 13, 1902.

751,161. Perforator for Use with Automatic Telegraph Transmitters. John Gell, London, Eng. Filed Nov 3, 1902.

751,164. Apparatus for Perforating Tape for Automatic Telegraph Instruments or the Like. John Gell Wellington, New Zealand. Filed May 9, 1903.

751,179. Process of Electrolytically Purifying Juices Alexander Kollrepp, Berlin, and Alfred Wohl Charlottenburg, Germany. Filed June 10, 1902

751,193. Electrical Alarm Device. Burnett Men Philadelphia, Pa. Filed July 30, 1901.

751,363. Printing Telegraph Receiver. James D. Whi London, Eng. Filed June 19, 1903.

THE TELEPHONE WORLD.

Independent Telephone Convention for Ohio.

The meeting of the Ohio and Indiana Independent Telephone Association, to be held in the Grand Hotel in Cincinnati, Wednesday, Thursday and Friday, February 17, 18 and 19, promises to be one of the most important in the history of the organization. Special rates have been secured on all railroads, and a number of manufacturers will make exhibits.

It is requested that those who are going to attend notify the secretary, E. E. Knox, Portsmouth, O.

The following programme has been arranged;

Wednesday, February 17, 9 A.M. to 3 P.M.—Registration and entertainment of delegates, secretary's headquarters.

Thursday, February 18, 10 A.M.—Reading of papers and discussions; 1 to 4 P.M., examination of exhibits; 8 P.M., the time-honored banquet will be dispensed with and a new and novel entertainment given without charge.

Friday, February 19, 10 A.M.—Reading of papers and discussions; 1 P.M., election of officers.

Telephone Merger in Iowa.

A merger of ten of the different telephone companies operating in Hamilton county has been effected in Webster City, and by the consolidation a second telephone exchange will soon be operated there. The companies which have merged are the Kamrar, Jewell-Wall Lake, Ellsworth Mutual, Williams, Stanhope & Northwestern, Randall, Jewell & South Cairo, Jewell & Northwestern, Stratford, Independent and the Blairsburg.

The following officers and directors were elected at the recent annual meeting of the Independent Consolidated Telephone Company held in Milwaukee, Wis.: President and manager, A. L. Hutchison, Weyauwega; vice-president, Dr. G. C. Marlow, Lancaster; secretary and treasurer, N. W. Low, Weyauwega; general counsel, E. R. Hicks, Oshkosh; general superintendent, O. Morseman, Milwaukee; general agent, John Kidd, Milwaukee; directors: A. L. Hutchison, Dr. G. C. Marlow N. W. Low, E. R. Hicks and John Kidd.

At the annual meeting of the stockholders of the Maryland Telephone & Telegraph Company, held in Baltimore a short time ago, the following directors were elected for the ensuing year: George R. Webb, David E. Evans, Frank A. Furst, Robert Ramsay, C. I. T. Gould, John T. Stone, Harry W. Webb, John Hubner, John Waters, H. A. Parr and Frank H. Callaway. The board re-elected George R. Webb president, David E. Evans vice-president, Stanley Baker secretary, R. F. Bonsal treasurer, and Harry W. Webb general manager.

Athens, Ga., may have a new telephone system within the next few months. L. D. Goodrum, of Pennsylvania, has been in that city representing one of the large construction companies of Pennsylvania, and agrees to furnish 'phones to business houses at $30 per annum, and to private residences for prices ranging from $18 to $24 per annum. If the requisite number of citizens agree to take the new 'phones, the company will proceed to install the system at once.

Wisconsin Independent Companies Hold Convention.

The annual convention of the Independent telephone companies of Wisconsin is now being held at the Hotel Pfister, Milwaukee, and will be in session two days, February 10 and 11. The Wisconsin association is one of the strongest of the State organizations. The question of an Independent exchange in Milwaukee will be taken up and plans formed for carrying out this undertaking. Other matters of great importance to Wisconsin companies will be discussed and an effort made to secure the co-operation of all the companies in dealing with these problems. Some of the prominent telephone men of neighboring States will take part in the programme. The more important telephone manufacture and supply houses have arranged to make displays of their apparatus.

Northern Illinois Independents Meet.

The Northern Illinois Independent Telephone Association, a district organization embracing most of the Independent companies in Northern Illinois affiliated with the Inter-State Independent Telephone Association, recently held a convention at Aurora. Twenty-two delegates were in attendance and formed a temporary organization by electing A. B. Conklin temporary president, and R. H. Gibboney of Rockford secretary.

The latest annual report of the Pennsylvania Telephone Company shows that an unusual amount of reconstruction, particularly to lines in Harrisburg, was done during the year 1903, and that many extensions and improvements were carried forward. This reconstruction included rebuilding 368 miles of toll lines and replacing 758 miles of iron wire by copper metallic circuits. In addition to the dividend of 6 per cent., the revenue of the year provided for equipments of the sinking fund, leaving a substantial balance to be carried to the surplus account.

At a recent meeting in Atlanta, Ga., of the electric light committee, it was decided to accept the bids of both the Southern Bell Telephone Company and the Atlanta Telephone Company for furnishing the city telephones during the next five years. The Atlanta Telephone Company will furnish 20 telephones besides its free list of 24 at $36 a piece. Under the new contract with the Southern Bell Telephone Company, the city gets 12 'phones free, and receives a discount of 33 per cent. on those it pays for. This is a great saving over last year.

The Narberth, Pa., borough council recently decided to permit the Delaware & Atlantic Telephone Company to string its wires on the telegraph poles and so give its telephone service to many citizens whose applications have been in for a long time. This ends a dispute that has been going on for some time, the council having insisted that all the wires be put underneath the ground. The telephone company has agreed to do this in four or five years, when in its estimation there would be business enough to do it.

Independent System for Mississippi.

The proposition of Messrs. Jones & Winters of Chicago, to establish an Independent telephone system in Meridian, is meeting with almost unanimous approval, and it is thought that not many months will be wasted before another company has been launched in that city to oppose the Bell system. F. E. Gressett, of Meridian, is corresponding with the Chicago firm relative to constructing the Independent system,

The stockholders' annual meeting of the Benzie County Telephone Company was lately held in Benzonia, Mich., and the official reports showed the company to be in a prosperous condition. Four years ago, on October 10, the company was represented by six stockholders with a paid-up capital of $620. It now has 111 stockholders, representing $35,000 capital. The State line tolls have increased over 100 per cent. and the local tolls nearly as much. The company now has over 200 miles of pole lines, 11 exchanges and 14 toll stations. W. A. Poung was re-elected president and general manager, and H. B. Woodward, secretary and treasurer. The directors are as follows: G. M. Sprout, E. Juergenmeyer, G. C. Woodward, J. Smeltzer and O. E. Putney. An 8 per cent. cash dividend was declared.

William Willison, John Heiber, Dr. Simpkinson and William Wilkinson, all residents of the river road between Ft. Thomas and Ross, Ky., have made application to the Citizens' Telephone Company of Kentucky, through their solicitor, James D. Robinson, for an extension of the company's lines from Ft. Thomas to Ross. Mr. Robinson has obtained a sufficient number of subscribers to warrant the company in extending the lines at once, which will include telephonic communication with Ross, Mentor and intervening points.

The eastern part of Branch County, Mich., is becoming famous for its rural telephone lines. There is now one line in operation starting from Quincy, covering a distance of 15 miles, with over 100 subscribers. Five other lines are already started from as many different directions, all headed for Quincy, and will be in operation as soon as the weather will permit of completing the construction.

Thomas C. Callister and James A. Kelley have installed their telephone system in the eastern part of Millard County, Utah, and intend to connect with the western part of the county at Oasis as soon as spring opens.

Telephone Incorporations.

The Dunn County Telephone Company, Ridgeland, Wis. Capital stock, $10,000. Incorporators; M. L. Randall, A. L. Gratz and J. L. Fergus, all of Ridgeland.

The Telephone Hygienic Company, Cleveland, O. Capital stock, $100,000. Incorporators: H. H. Johnson, George G. Whitcomb, F. B. Williams, T. H. Hogsett and George H Kelly.

The Center Point Telephone Company, Center Point, Ind. Capital stock, $5,000. Directors; H. F. Weber, L. Lansit, Milo A. Campbell, R. M. Bryant and H. Allendorf.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Bellows Falls, Vt.—The Fall Mountain Electric Light & Power Company of this place has decided to extend its system to the village of Saxtons River, about five miles distant. The company will furnish street lights as well as house lights and power.

Bowmansville, Ont.—It is reported that the Bowmansville Electric Light Company will build a new dam and enlarge its plant in the spring.

Canton, N. Y.—The Canton Electric Light & Power Company, of which W. R. Remington is president, is said to be contemplating improvements this year.

Chicago, Ill.—Proposals will be received by the South Park Commissioners at their office until February 17 for the furnishing and delivery of about 3,000 feet of electric light cable. Address Edward G. Shumway, secretary.

Cisco, Tex.—The Cisco Electric Light Company has been incorporated with a capital of $10,000. The directors are A. L. Mayhew. W. A. McSpadden and others.

Cleveland, O.—The council appropriation ordinance for the first half of 1904 will contain an item of $200,000 for a municipal lighting plant.

Coatesville, Pa.—The erection of a village electric light plant is being contemplated.

Creston, Ia.—Mayor J. C. Sullivan, is projecting an electric light company.

Emmett, Ida.—J. H. Forbes and C. H. Oliver have entered into an agreement with this village whereby they agree to put in an electric light plant within nine months. They will put in a steam engine and boiler of 120 hp.

Fillmore, Utah.—The city officials are making an effort to install an electric light plant here early in the spring.

Flint, Mich.—An investigation made by the special light commission shows that this city can install an electric lighting system for $28,000.

Hannibal, Mo.—The citizens have voted to issue $100,000 of bonds for installing a new electric light plant.

Hersey, Mich.—The flouring mills here recently destroyed by fire will be rebuilt. The new plant is also to be equipped with machinery to light the streets of the village with electricity.

Hilton, N. Y.—The people of this place are greatly in favor of an electric lighting plant.

Indianapolis, Ind.—City Engineer K. Jeup has completed plans and specifications for the public electric lighting, and bids will probably be received in five or six weeks. A contract has been drawn for 10 years, and provides for furnishing a minimum of 1,600 lights and a maximum of 2,100.

Kewanee, Ill.—The stockholders of the Kewanee Light & Power Company have authorized the expenditure of $50,000 this year for improving the plant.

Koochiching, Minn.—The village council has adopted a resolution calling for bids to install a municipal electric light plant.

Kutztown, Pa.—The project of lighting Cottage Grove avenue with electric lights has been revived.

Long Beach, Cal.—A municipal electric light plant is being petitioned for. W. A. Foster is city engineer.

Mason City, Ia.—The city is considering the matter of installing an electric light plant. The citizens may vote on the proposition at the next election.

Mitchell, S. D.—The electric company has disposed of the electric lighting plant in this city to J. B. Mickelsell and Fred Fairchild, both of Plankinton. The new proprietors will increase the capacity of the plant and add new machinery.

New Orleans, La.—The Consumers' Electric Company, of which Jules Dreyfous is president, will, it is stated, at once proceed to erect a large plant.

Northumberland, Pa.—The Northumberland Light, Heat & Power Company has invited bids for a new plant of about 250 hp.

Palouse, Wash.—The electric light system here is to be materially extended.

Preston, Ont.—The town council has engaged R. A. Ross, electrical engineer of Montreal, to report on the value of the existing electric light plant, and the cost of installing a new plant.

Reading, Pa.—Mr. Wunder has presented an ordinance to provide for the holding of a special election to secure the assent of the voters to a loan of $200,000, for the purposes of erecting, maintaining and operating an electric light plant.

Richibucto, N. B.—The establishment of an electric lighting plant here is possible. Richard O'Leary and H. H. James are interested.

St. Marys, O.—This city will sell $20,000 worth of electric light and waterworks bonds March 1.

Virden, Ill.—The Virden Electric Light Company has been incorporated with a capital of $15,000 by J. M. Hairgrove, U. G. Tucker and C. W. Carr.

Walnut, Ia.—The city council has adopted plans for a $14,000 electric light plant.

Webster, S. D.—A committee has been appointed by the city council to investigate the capacity of the machinery in the power house for the increased demand of electric lights.

Woonsocket, S. D.—The business men are contemplating the installation of electricity to light the streets of this city.

Zionville, Ind.—There is a movement on foot to build an electric lighting plant here.

STREET RAILWAYS.

Albany, N. Y.—The Electric City Railway Company, of Niagara Falls, was incorporated last week to operate a street surface road, eight miles long, in Niagara Falls. The capital stock is $80,000 and the directors are Alvah K. Potter of Lockport, and Arthur Schoelkoff, James S. Simmons, Henry H. Findlay, S. P. Fanchol, Patrick F. King, Henry L. Colpays, Frank E. Reid and Frederick J. Brown, of Niagara Falls.

Arkansas City, Kan.—L. H. P. Northrup, who was given a franchise to build an electric railway in this city and an interurban road between here and Winfield, and this city and Chilocco, has employed Thomas V. Hall & Co., consulting engineers, and the latter will have civil engineers begin the survey about the 15th of this month.

Bordentown, N. J.—The Camden & Trenton Railway Company, in which M. J. Perkins o Riverside is interested, has invited bids for the addition to its power house here. A complete line of new equipment, boilers, generators, etc., will be installed,

Chanute, Kan.—D. W. Spooner, chief engineer of the proposed railway known as the Spooner road, which has been surveyed to run through this section from Joplin to this city, declares that the road will be built this summer.

Denver, Col.—An electric railway capitalized at $1,000,000, is projected for freight and passengers through Weld and Larimer Counties.

Far Rockaway, N. Y.—The agitation for a new and direct road leading from the Bayswater section to the ocean front and to Edgemere and Rockway Beach has brought about a desire among residents in that section to have the trolley extend its tracks through Bayswater.

Greenville, S. C.—Construction will soon begin on the interurban trolley between this city and Anderson, belting the thickest settled mill district in the South.

Hillsdale, Mich.—Dr. P. P. Duckett is president of the new electric road that is to be built here.

Kingman, Ind.—Col. A. G. Madden, of this city, has promoted an electric road from Covington to Rockville, which will be financed by Eastern capital.

Richmond, Va.—Because the city council threatens to require the Virginia Passenger & Power Company to install a combined double overhead trolley and underground conduit system at an enormous expenditure, Frank Jay Gould, the principal owner of the road, has ordered all work of improvement in this city and Petersburg to stop.

Taylorville, Ill.—The Corn Belt Traction Company has been incorporated with a capital of $210,000.

Ventura, Cal.—John Burson, has announced that active construction upon the Ventura-Bakersfield Electric Railway would begin February 15, and that by March 1 between 500 and 1,000 men will be employed.

Vincennes, Ind.—The Vincennes, West Baden & Louisville Traction Company has been awarded a franchise to construct and operate an electric line here.

POWER PLANTS.

Kenosha, Wis.—The Kenosha Gas & Electric Company has decided to add an electric power plant at a cost of $10,000.

Lindsay, Ont.—The Eugenia Falls Water Power & Electric Company has been organized to develop water power. George F. Madden of Toronto and E. F. Reesor of this city are interested.

New Freedom, Pa.—A. Reehling, clerk, states that an election will be held February 16, at which the matter of power plant and waterworks will be voted on.

Petersburg, Va.—The Virginia Passenger & Power Company is now building a dam in Dinwiddie County, five miles above here, to furnish water power for two electric plants to be established, one at this dam and the other at the locks, two miles above this city. This dam, with the two plants, will cost $1,500,000.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12½@12⅝c.; Lake 12⅜@12½c.; casting, 12⅛@12¼c.

The time for depositing Chicago Lake Street Elevated securities has been extended to March 5.

A meeting of the stockholders of the United Traction Company, Albany, N. Y., will be held on March 1.

The Boston Elevated Railway Company has declared its regular semi-annual 3 per cent. dividend, payable February 15.

Demand in Philadelphia for United New Jersey continues at 266; the market has, however, been pretty well cleaned up of the stock.

The report that the Allis-Chalmers Company will extend its field to the manufacture of electrical machinery is confirmed in Chicago.

A director of the Philadelphia Electric Company was quoted as authority for the statement that an assessment will be levied on the stock in a short time, possibly in April.

The Kings County (Brooklyn) Electric Light & Power Company has declared the regular quarterly dividend of 2 per cent., payable March 1. Books close February 20 and reopen March 1.

General Electric and Westinghouse stocks declined nearly five points on Monday. The coming decision on the franchise tax, the Baltimore fire and war news were the alleged causes of the decline.

The next dividend on Cincinnati Street Railway stock in April will be at the rate of 6 per cent. per annum, and this rate will be guaranteed by the Cincinnati Traction Company (the Widener-Elkins Syndicate).

The United Traction Company, which operates the street car system in Albany, Troy, Cohoes, Watervliet and Rensselaer, N. Y., on Saturday gave a mortgage of $6,500,000 to redeem outstanding bonds and improve the road.

At the stockholders' annual meeting of the Western Electric Company, C. W. Amory, Thomas Sherwin and Charles Williams, Jr., retired from the board of directors and were succeeded by Charles S. Holt, James W. Johnston and Charles G. Dubois.

Interborough Rapid Transit stock suffered a heavy decline on Monday. From the top price of the day, 104½, a decline to 101½ was made, netting a loss of 3 points. Subsequently about a point of this loss was recovered, the stock closing at 102¼.

The trolley car system of Baltimore was partially resumed on Monday evening, an hour or two after the great fire, which raged for nearly 38 hours, had been brought under control. The main power house is a total wreck and it will take weeks to replace it.

The proposition of the Massachusetts Electric Companies for more power is gradually rounding into shape. The management is laying out between $2,500,000 and $3,000,000 in new power plants, scattered over its entire system, but it will take two years to complete this work, owing to the delay in securing turbine engines from the General Electric Company. Already nearly $10,000,000 of new money has gone into the properties, yet the extent of the lines is so great that this large expenditure of money is hardly noticeable except to the directors, who realize the condition of the 39 properties when they were put together into two great systems controlled by the Massachusetts Electric Companies.

EDITORIAL NOTES.

The Proposed Engineering Building.

As probably every member of the American Institute of Electrical Engineers is aware, Mr. Andrew Carnegie has offered to donate one million dollars or more for a new and up-to-date engineering building to be made use of jointly by the Institute, the American Society of Civil Engineers, the American Society of Mechanical Engineers, the American Institute of Mining Engineers and the Engineers' Club.

As is generally known by the engineering fraternity the preliminary plans for this building include a general meeting room, committee and other rooms for each of the societies, in addition to a general and well equipped lecture room for large meetings of the above mentioned and kindred societies; and a large and handsome library room, a section of which may be used by each of the societies, or separate library rooms for the respective societies, as they may prefer. The home of the Engineers' Club will be in a separate adjacent building.

In order to secure the benefits which will accrue to the profession generally, and to the membership of the societies in particular, from such an attractive and permanent home as is planned, it is necessary for the societies to furnish the site. The latter can only be obtained through contributions, and the members of the Institute should one and all donate something, if only a small sum, towards the fund. Men as busy as are electrical engineers frequently procrastinate in matters of this kind, but the securing of a site for this new building is too important to be lightly shoved aside—so be sure and put your name down *at once* on the subscription blank that the Secretary of the Institute Committee sends you.

New York Tunnels.

Everything seems to indicate that before many years pass there will be a network of rapid transit tunnels under Manhattan Island.

Reports that the Interborough Rapid Transit Company, of which August Belmont is at the head, had prepared plans to connect the subway system of Manhattan with the trolley lines in Queens by means of a tunnel under the East River were practically confirmed last week, when it was learned that engineers had been at work on the plan for some time.

Mr. Belmont has acquired a controlling interest in the old Steinway syndicate which proposed to build a tunnel from Long Island City to 42d street, Manhattan, and thence to 10th avenue. Work on this tunnel was begun several years ago, but an explosion in the shaft in Long Island City crippled the old corporation financially. Mr. Belmont purposes to conduct the undertaking as a private enterprise.

When the tunnels under the North River are completed it is said that a complete system of transfers will be established whereby passengers can ride from Long Island City to New Jersey, the connecting link being supplied by the rapid transit subway.

Engineers who have studied the proposition have reported that the tunnel can be built in less than two years. It is to be located several blocks north of the Pennsylvania Railroad tunnel and below the Blackwell's Island bridge. The present trolley lines in Queens cover 60 miles of track and carry nearly 12,000,000 passengers a year. The tunnel plans may be submitted to the Rapid Transit Commissioners this month.

In spite of all the tunnels that are being built Greater New York is really behind the times and the work should have been

begun several years before it was. By the time the rapid transit tunnels are completed and electric trains running the population of the city will have increased to such an extent that the facilities for rapid transportation will be inadequate.

Owing to the peculiar shape of Manhattan Island possibly no real relief from congestion of traffic will be had until air-ships are perfected.

* * *

The Bell Company's Financial Needs.

It has at last been finally decided that the American Telephone & Telegraph Company (Bell) will need $20,000,000 this year, and a leading interest in the company intimates that "a part of the new capital issue will be for the acquirement of certain independent companies which it can secure at an equitable price."

Of course the "acquirement of independent companies" is only talk, but is good bait to throw out when issuing new bonds "to be later convertible into stock," and we think that before President Fish returns from his trip to the Pacific coast he will learn that the independent movement is making rapid strides—not only on the coast but throughout the West.

Since January 1 rumors have been plentiful that the American Telephone & Telegraph Company might make an issue of convertible bonds this year, but some one in authority would send out a report that "the company declared that absolutely no consideration had yet been given the question of the company's financial needs this year and therefore any reports as to the company's intentions had no foundation, in fact the directors had not reached the point of considering suggestions."

Now comes official news from headquarters, issued on Friday last, that "the American Telephone & Telegraph Company will this year need $20,000,000, but it may not need this money until fall, although the company generally raises its money in July. It may be that the company will this year issue convertible 5 per cent. bonds. It may be considered better policy for the American Company to become a borrower of money this year than issue new securities if market conditions are not better next summer than at present."

We guess that President Fish will discover before he returns from the coast that it will take a "bunch" of money to carry on the war against the independents, and that he will not wait until the "good old summer time" before sending out his pronunciamento to the dear public that the $20,000,000 convertible bond issue is ready for investors.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The next annual business meeting of the American Electrochemical Society will be held in Washington, D. C., April 7, 8 and 9.

The Interurban Street Railway Company of this city has changed its corporate name to the New York City Railway Company.

Late news from Baltimore says that revised estimates of the fire losses are now placed at $85,000,000 or less, three-fourths of which are insured.

Mayor Weaver of Philadelphia declared himself on Saturday as unqualifiedly in favor of three-cent fares on city trolley cars. "I would like to see the city own its street railway lines," he said, "and charge three-cent fares; but I question the practicability of municipal ownership of the railways at this time."

Radium in the mica deposits of the eastern and western provinces of Canada is an alleged discovery that has caused a stir in Ottawa. Mr. Obalski, Government inspector of mines, is certain that the rare metal will be found in quantities.

The quarterly meeting of the board of directors of the National Electrical Contractors' Association was lately held in Washington, D. C. The directors paid a visit to the White House, where they were received by the President, who expressed his pleasure at meeting the directors, and called their attention to the large and constantly expanding field for electrical work offered by the Philippines, The next meeting will be held in St. Louis September 13-16, at which time officers will be elected.

Frederick S. Dickson, president of the Cuyahoga Telephone Company of Cleveland, O., has won his fight against President Roosevelt and Postmaster General Payne. The latter, with the President's sanction, ruled that post offices throughout the country should use only one telephone, viz., the one that had long distance connection with Washington. This meant the loss of a large sum to the independent telephone interests of the country. Dickson pleaded with President Roosevelt to intercede, but without success; but through many Senators and Representatives he has succeeded in getting the Payne ruling modified so that the independents will have a chance.

The largest searchlight in the world has been completed and will be used for advertising purposes at the Louisiana Purchase Exposition. The machine weighs 7,000 pounds, is of 2,250,000 cp., and projects a beam of light 7 feet in diameter.

An electrical system of stock raising has been developed on a moderate scale at the University of Michigan. Small animals, such as rabbits, have already been forced into matured size and plumpness in two-thirds of the period required by nature, showing the possibility of forcing the development of the larger stock.

The National Electric Light Association is sending out a notice to members regarding Mr. Henry L. Doherty's offer of a gold medal for the best and most practical paper on underground construction. Papers must be received at the office of the association not later than April 21. Three copies of each paper are requested.

A Government sanction has been obtained for an electrical exhibition to be held at Warsaw, Russia, from May to September of this year. The exhibition will include a special section for new inventions in this direction and foreign exhibitors are invited to take part. It is understood that permission is to be granted for the admission of exhibits free of duty. Interested parties should address the committee, Philharmonia Building, Moniuszki street, Warsaw.

The 241st meeting of the New York Electrical Society will be held at the rooms of the American Institute, 19 West 44th street, this (Wednesday) evening, February 17, at 8 o'clock. Mr. Ralph D. Mershon will lecture on "The Gas Engine for Central Station Service."

Owing to differences of opinion between the State, the municipal authorities and the owners of the Tuileries Garden in Paris, the electric lighting of the garden has been much delayed. The main question in dispute, as to who should direct the work, has been settled in favor of the State, and although the city engineers are actually conducting the operation of laying the wires, it is under the direction of the Government. The type of lamp decided upon by the latter is known as "Arc Nouveau."

A NEW INCLOSED LIQUID STARTING RESISTANCE.

BY FRANK C. PERKINS.

The accompanying diagram, Fig. 1, and illustrations, Figs. 2 and 3, show the details of construction of a most novel and ingenious motor starter, designed by Mr. J. H. Woolliscroft of the Sandycroft Foundry Company, Ltd., of Chester, England. The motor starting switch, seen in Fig. 2, is of the three-phase 40 hp. type and consists of a water-tight cast-iron drum, containing soda and water and fitted with internal electrodes and external contacts and terminals.

The cast-iron drum is carried on insulating bearings and is provided with an opening for supplying the liquid, the plug closing the same acting as a relief valve for the gas generated by electrolysis. The lever rotating on the axis is held by a catch when in a vertical position, while the cast-iron case containing the liquid is free to rotate when picked up by the catch actuated by the retaining coil in series with the field. The sliding con-

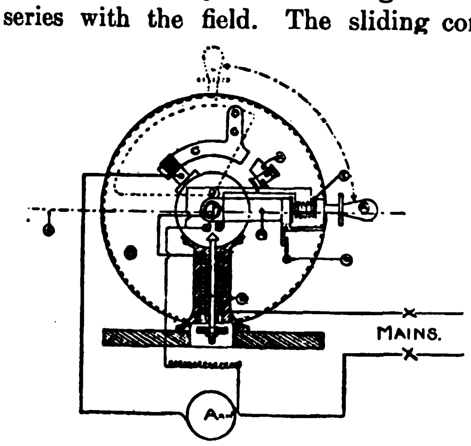

Fig. 1.—Diagram of Connections.

tact is fixed to the internal blade and rotated with the case but is insulated from it. In Fig. 1, A represents the lever, B the cast-iron case, C the sliding contact, while D is the maximum release protected inside the cast-iron bearing pedestal. The retaining catch can be seen, while the level of the liquid is indicated at F and the minimum release and catch-retaining coil is shown at E. The short circuit contact, H, is fixed at B and J, and shows the position of the insulating bearings.

The minimum release and retaining coil is in series with the shunt winding of the motor, and is carried on a lever which forms a handle rotating on the same axis as the drum. When this is energized a catch is brought into gear with a trigger on the drum, the latter being rotated by means of the handle. As the drum is caused to revolve the electrodes dip into the liquid and gradually cut out the resistance of the latter in the main circuit. By means of the special contact, H, at the extreme end of the travel of the drum the resistance is finally short-circuited.

The maximum release coil is inclosed in one of the cast-iron bearings and in case an excessive current is used during the

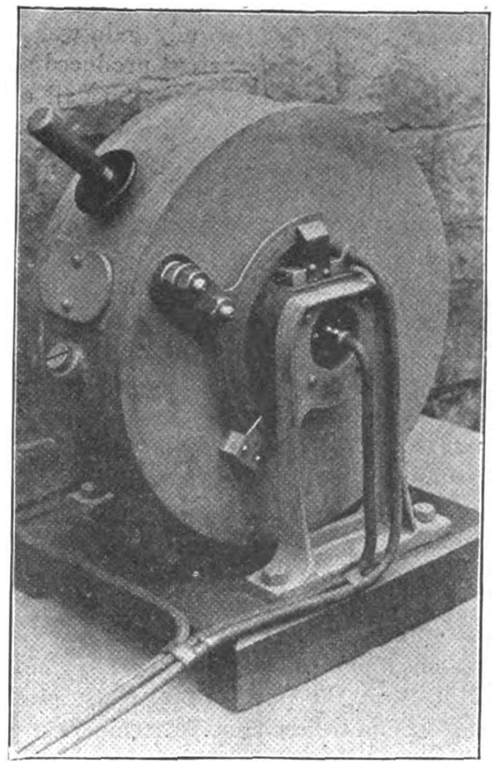

Fig. 2.
40 B.H.P. Three-phase Motor Starting Resistance.

starting or while running the motor the minimum coil is short-circuited and allows the drum to return to the off position by

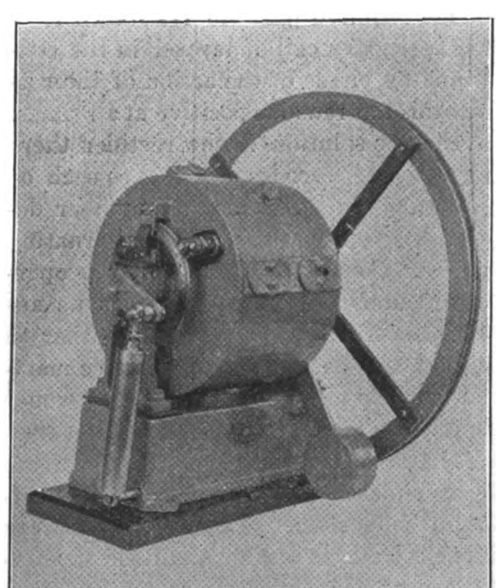

Fig. 3.
Automatic Liquid Switch for Intermittent Pump Work, Organ Blowing, etc.

gravity. This safety inclosed resistance for shunt motors, shown in the diagram, is extremely simple and safe—over-heating, sparking and irregular steps being avoided. It is provided with the usual precautions against starting the motor too quickly, excessive overloading, leaving the resistance cut out in case of current supply or switching on the armature before the field is excited.

The main switch is of course always used for stopping the motor, and the shunt will remain closed on the armature and will hold up the starter until the EMF. is reduced to zero. The electrolyte is varied in density according to the voltage used, this resistance being suitable for pressures up to 800 volts, while it is impossible to burn it out. The illustration, Fig. 2, shows a Woolliscroft inclosed liquid switch for intermittent pump work and organ blowing.

THE ELECTROLYTIC RECTIFIER AND INTERRUPTER.*

BY W. B. CHURCHER.

It is a well-nigh settled fact that there is nothing absolutely new under the sun. To the ordinary observer it matters little how much study and hard work an inventor may have given his product before it becomes a marketable commodity and he is always ready to listen to the claims of invention by some one in the obscure past who had a vague idea in his head upon the same subject. It always remains for some one not only to invent a device but to put it into such a practical shape that it can be made a useful article to society and indirectly a producer of the "where-with-all" with which other useful articles may be made available. It is not such a difficult matter to invent something new, comparatively speaking. Much hard work must be done, difficulties overcome, methods of manufacture and sale perfected before any real success is achieved. Such has been the case with the alternating current rectifier, about which more or less has been written in the last few years. It is not a newly discovered fact that aluminum and some other metals have the faculty of developing upon their surfaces an insulating film when in contact with certain solutions and while electrically positive to another electrode in the same solution, but it has remained in an unperfected state. The Churcher alternating current rectifier is a decided departure from anything before constructed and is now in marketable and practical shape. The best that has been accomplished heretofore was a very inefficient and crude device. A single cell with a pair of suitable elements will rectify part of the cycle of an alternating current, but this is not

* Paper read at the twelfth annual convention of the Northwestern Electrical Association held at Milwaukee, Wis., Jan. 20-22, 1904.

a true uni-directional current. It is still an alternating current in character with one alternation of greater amplitude than the other and giving an efficiency of perhaps 20 per cent. when charging a storage battery. This poor result is partially caused by the return or leakage current passing through the rectifier and through the battery in the wrong direction, hence discharging it. To charge a storage battery under this condition it is evident that an excessive charging current must be used to overbalance the excessive discharge that takes place during one-half of the cycle. For example, in figures that are approximately correct, to charge a battery of cells aggregating 50 volts, a potential of about 60 volts is ordinarily required. Supposing for illustration that this potential will pass 10 amperes through the cells on direct current circuit. In order to charge at this rate from an alternating current with a single old type rectifier it will be necessary to raise the charging potential sufficiently, say to 75 volts, to force 50 amperes through the cells—an excessive charge. This is because of the fact that the potential of the return wave of the alternation will be added to that of the battery and produce a serious leak through the insulating film on the aluminum electrode. The average charge potential available would be 75 less 50 or 25 volts while the average discharge potential would be 50 plus 75 or 125 volts. Average, because at the peak of the alternation the actual potential would reach about 100 volts at this point the potential against the film would be about 150 volts, which is approximately its break-down point. This high return potential, as it may be termed, will cause a discharge of about 40 amperes—an excessive discharge. This leaves a net charging current of 10 amperes. It is presupposed that a battery requiring 10 amperes would have a capacity of about 100 ampere hours, and hence it will be seen that in order to charge at 10 amperes from the old type of rectifier it was necessary to charge at 50 and discharge at 40 amperes leaving the required margin for charging. At this rate the rectifier would be rapidly destroyed and the best storage battery would be served likewise. A rectifier of this type is not worthy of further consideration, as it is of no more real value for other purposes than for charging batteries.

The next step was a combination of four rectifying cells, known as the Gratz method of connection. This combination was somewhat better in that it rectified both waves of the cycle and hence gave a true uni-directional current. The efficiency was necessarily low because of the fact that the resistance in the path of the useful current was doubled and the leakage current was also doubled. The old type of single cell being inefficient to start with the combination of four was four times as bad, to say nothing of the wear and tear on four sets of electrodes and four solutions. The only gain was a really uni-directional current produced so that in charging a storage battery all of the energy passing through it was available for discharge, barring, of course, inherent losses peculiar to storage batteries.

The next step was the perfection of the Churcher rectifier. This device rectifies both waves of any alternating current and requires but one jar, one solution and one set of electrodes to do so. In this way the internal resistance is reduced to a very low point—in fact it is only limited by mechanical necessities to prevent short circuits. This loss is almost negligible. The loss that does take place is the small leakage current. This current does not pass through the apparatus operated by direct current but is expended in heating the solution. This loss is largely dependent upon the proper initial forming of the film, the purity of the aluminum and the solution and its temperature. Where continuous service is required of the rectifier it is therefore desirable to prevent this initial rise in temperature by the use of water-cooling pipes or radiation of some form. This form of rectifier requires the use of a transformer with a secondary of twice the direct current voltage required plus the resistance loss. This secondary coil is tapped in the center and by virtue of the action of the rectifier this tap remains positive at all times. In the one solution in the rectifier there are active electrodes attached to each of the secondary terminals, the number depending upon the phase of the alternating supply. Owing to the peculiar properties of films on these electrodes no appreciable current passes from either to the other. Electrodes of inactive material, such as platinum, carbon, etc., would short-circuit the transformer. Between these active electrodes but insulated from them is placed an inactive electrode, preferably platinum. Connected between this electrode as one terminal and the center tap of the transformer as the other is the battery to be charged, direct current motor or other apparatus to be operated. In operation the current passes from the center tap of the transformer to the motor, from the motor to the inactive electrode in the rectifier solution, thence through the solution to one or the other active electrodes, depending on which is at that instant negative to the center of the transformer. Inside the rectifier the current therefore passes from the inactive electrode, first to one then to the other active electrode as the alternations of the cycle take place, the center of the transformer remaining positive at all times. It will be understood from this that one side of the transformer is active while the other is inactive, and then reversed during the next alternation. The regulation of direct current is best attained by placing an adjustable inductance between the tranformer terminals and the active electrodes of the rectifier. This regulation can also be very efficiently attained by an inductance in the main alternating supply or by varying the number of turns of wire in the primary of the transformer. This form of regulation is, of course, much more efficient than placing resistance in series with storage batteries when charging from the 110 volt direct current mains.

It is also a well known fact that a pulsating uni-directional current is especially desirable for charging storage batteries. Just why it is so is not very well understood, but the fact remains. The limit of voltage of one cell of the Churcher rectifier is about 70 volts direct current or a difference of potential across the active electrodes of about 140 volts. Somewhat higher voltage may be obtained under favorable conditions, but the efficiency is generally much lower because of the increased leakage from one transformer terminal to the other. Through the use of two cells and two secondaries in the one transformer twice the voltage can be obtained; three cells with three secondaries in the one transformer will give three times the voltage, etc. Thus it is evident that the Churcher rectifier will deliver any potential of direct current from any alternating current. This statement may seem very broad but it is perfectly true. Potential, phase, cycles, direct current, are all matters of detail readily worked out by anyone familiar with the system.

An important application of the Churcher alternating rectifier is the interrupter exclusively designed by me. Full and complete claims for this invention as well as those on the rectifier have been allowed by the Government. This interrupter gives promise of extensive application in the X-ray field, as it is a well known fact that alternating current is very inefficient for such purposes, especially when the frequency is over 60 cycles. The Churcher alternating rectifying interrupter will receive any potential, any phase or cycle of alternating current and deliver a rapidly and completely interrupted direct current through the primary of an induc-

tion coil. Its construction and mode of operation is similar to the Churcher rectifier, the only difference being in the area of exposed contact of the positive electrode. The large area of the positive electrode gives a perfect contact with the solution, but in the rectifying interrupter the opposite condition is present. The positive electrode in this case is of restricted area; restricted to such a degree that instantaneous interruption of the current is obtained by the well-known Wehnelt effect. By the regulation of the amount of positive electrode exposed any volume of interrupted current can be produced. This interrupted direct current from the Churcher rectifying interrupter on alternating supply is more desirable for the purpose than the regular 110 volt direct current as the potential is somewhat less, and hence more easily and completely interrupted without destruction of its parts. These two inventions, however, mark a long stride in the subject of actually applied commercial electricity. The invention and perfection of the interrupter especially has excited the greatest interest in the field in which it is applicable.

ELECTRICAL STATION PRACTICE.

ARTICLE XXIV.

BY W. H. RADCLIFFE.

Next in importance to the alternators installed in a central station, in which alternating current is generated, are the transformers. By means of these the pressures developed in the alternators are increased many times before they are supplied to the line wires; this is done in order to proportionately decrease the currents and so reduce the loss in transmission due to the resistance of the line wires, which loss in any one installation is proportional to the square of the current. Transformers used in this manner at the generating end of the line to increase the pressures are called step-up transformers, whereas in sub-stations at the distributing end of the line other transformers are used to reduce the pressures to values which are considered safe for service, and these are termed step-down transformers.

Transformers as a whole are simple in construction, high in efficiency, and comparatively inexpensive. Their principles of operation are also readily understood. Essentially, a transformer consists of a closed iron core on which are wound two separated coils of insulate wire. One of these coils, known as the primary or low-pressure winding consists of a comparatively few turns of large wire, while the other coil, known as the secondary or high pressure winding, consists of a large number of turns of smaller wire. The proportion of the number of turns in the primary coil to the number of turns in the secondary coil is called the ratio of the transformer. The step-up transformer at the generating station has its primary coil in connection with the terminals of the alternator and its secondary coil in connection with the line wires; the step-down transformer at the receiving station has its secondary coil connected to the line wires and its primary coil joined to the distributing circuits.

The fundamental principles governing the operation of both step-up and step-down transformers are practically the same, but for illustration the step-up transformer at the generating end of the line will be considered. Suppose for the present that the connection with the line wires has not been made, but that the primary circuit of the transformer is being supplied with an alternating electromotive force by the alternator. An alternating current whose strength is directly proportional to the value of the impressed electromotive force and inversely proportional to the resistance and reactance of the primary winding will pass through it. This primary current encircling the iron core magnetizes it first in one direction and then in the opposite direction many times per second, depending upon the frequency of the current, which by the way is known as the magnetizing current of the transformer. There is, therefore, a certain loss of energy going on in the magnetization of the transformer core, no matter whether the secondary coil is in use or not. This loss is called the core loss of the transformer, and in any given case is practically constant at all times the transformer is supplied with current. The core loss, in reality, is composed of two approximately equal losses, the eddy-current loss and the hysteresis loss, both of which result directly from the reversals of magnetism within the core. The eddy-current loss may be made low by laminating the iron core of the transformer at right angles to the flow of the eddy currents; that is, instead of casting the core in one solid piece, building it up from sheet-iron strips of about 14 mils in thickness stamped in the desired shape and enameled or japanned on both sides. The hysteresis loss will remain within reasonable limits if the iron used for the core be of good quality and of sufficient cross-sectional area that it be not overcrowded with lines of force under normal conditions.

Let us next turn our attention to the conditions existing in the secondary coil which is yet an open circuit. Assuming there is no leakage of the lines of force outside the iron core, all of them intercept the secondary coil upon each reversal of the alternating current and therefore develop therein an alternating electromotive force which is proportional to the number of turns composing this coil multiplied by the rate of change of the lines of force through it. Stated in another way, there is developed in each turn of the secondary coil an electromotive force which is equal in value to that in each turn of the primary coil; consequently the total electromotive force that may be obtained from the secondary coil will be that proportion of the primary electromotive force as the number of turns in the secondary coil is to the number of turns in the primary coil.

Now, suppose that the necessary connections be made between the secondary coil and the line wires so that this circuit is closed. The electromotive force developed in the secondary coil will now, since the secondary circuit is closed, force through this circuit an alternating current which will have the same frequency or number of reversals per second as the primary current. There will, however, be a difference in phase of approximately 180 degrees between them; that is, the direction of the induced secondary current at any one time is nearly opposite to that of the primary current, tending in consequence to decrease the magnetization of the transformer core. This tendency to decrease the number of lines of force through the core is proportional to the strength of the secondary current, but there is an inclination for the primary current to increase on account of the lower magnetization, so that the result, so far as the core is concerned, is actually unchanged. Owing to this tendency for the primary current to increase with an increase of secondary current, the transformer is practically self-regulating, and since the resistance loss of the transformer is equal to the product of the resistance of the primary winding and the square of the primary current, this loss consequently varies according to the strength of current in the secondary circuit.

The three losses previously mentioned (the eddy current loss, the hysteresis loss, and the resistance loss in the primary winding) together with the resistance loss in the secondary winding, which latter is equal to the product of the resistance of the secondary winding and the square of the secondary current, constitute the factors tending to decrease the efficiency of the transformer from the ideal mark of

100 per cent. Of these four losses we have seen that two of them are practically constant at all loads, and that two vary as the square of the currents. The efficiency of a transformer, that is, the ratio between full load primary and full load secondary, will therefore be greatest when the load on it is such that the sum of the constant losses equals the sum of the variable losses. In general, transformers designed for high frequencies and large capacities are more efficient than those designed for low frequencies and small capacities. As a whole, however, a transformer leaves but little to be desired as regards efficiency, a modern 60-cycle transformer of 50 kilowatts capacity or more possessing an efficiency of approximately 98 per cent. at full load and an efficiency of about 97 per cent. at half load. In designing a transformer it is important to so proportion its parts that the point of maximum efficiency occurs at that load which the transformer usually carries in service. In many alternating current installations, comparatively light loads are carried the greater part of the time, the rated full load or an overload being occurrences of short durations. For such purposes special attention should be given to the designing or selecting of transformers having low core losses rather than low resistance losses, because the latter are then of relatively small importance.

The "all-day efficiency of a transformer" is an expression commonly met with in practice, and denotes the percentage that the amount of energy actually used by the consumer is of the total energy supplied to his transformer during 24 hours. The formula for calculating the all-day efficiency of a transformer is built upon the supposition that the amount of energy used by the consumer during 24 hours is equivalent to full load on his transformer during 5 hours, and is as follows:

$$E = \frac{5w}{24c + 5r + 5w}.$$

Here E = the all-day efficiency of the transformer,
w = the full load in watts on the primary,
c = the core loss in watts,
r = the resistance loss in watts.

The all-day efficiencies of modern types of transformers average about 85 per cent. for those of 1 kilowatt capacity, 92 per cent. for those of 5 kilowatts capacity, 94 per cent. for those of 10 kilowatts capacity, and about 94.5 per cent. for those of 15 kilowatts capacity.

The energy dissipated in the losses of a transformer reappears as heat in the windings and core. This heat not only increases the resistances of the windings and core, producing thereby a further increase of their respective losses, but in addition causes in time a peculiar effect on the iron core which is intensified by the reversals of magnetism constantly going on within it. After about two years' service, the iron apparently becomes fatigued or tired, and this phenomenon is called aging of the iron. Since the life of the transformer depends to a great extent upon this factor, the conditions responsible for its existence should as far as possible be removed. Means must therefore be provided in the construction to radiate the heat as quickly as it is generated. In transformers designed for low outputs, that is in those having capacities below 10 kilowatts, sufficient radiation is obtained by exposing the core and windings as much as possible to the surrounding air. The amount of heat thus dissipated under a given rise of temperature, increases proportionately to the amount of surface exposed, but since in transformers of large outputs the amount of surface exposed to the air per unit of capacity is not as great as in transformers having low outputs, other modifications of this method and other mediums more efficient than air, are brought into service for the purpose of cooling the working parts of these transformers.

A modification of the method just mentioned consists in forcing a continuous blast of air through the core and coils, both of which are spaced so as to provide a system of air ducts which permit of a free circulation of the air. The air blast is maintained by a blower usually operated by an electric motor, and where several transformers of this type are in use a single blower can generally be arranged to furnish an air blast that will be sufficient for the entire installation. The pressure of the air in each transformer may be regulated by means of a damper in its cover, and the amount of air passing through the ventilating ducts in the core may also be governed by another damper in the side of each transformer.

Oil is also used to a great extent in transformers for dissipating the heat of the windings and core by conducting it to the transformer case. The oil entirely surrounds both the core and coils, and is held in an iron case which completely surrounds the working parts of the transformer, and which is corrugated to increase the amount of surface exposed for radiation. Oil is not only more efficient than confined air in this respect, but its high insulating properties and its puncture-repairing qualities render it particularly adapted for use in installations employing high pressures and heavy currents. In order that the insulation on these leads from the primary and secondary coils of this type of transformer may not act as a wick and thus draw out the oil, the insulation on these leads is removed for a portion of their length and insulating sleeves of special construction used in their stead.

In alternating current installations, where particularly heavy currents are employed, and where the heat developed within the transformers is therefore considerable, special means are taken to maintain the temperature of the oil used therein, at a low temperature. The device employed consists of a coil of pipe surrounding the top of the transformer, and through which a stream of cold water is forced. The oil in contact with the core and the windings thereon, becomes heated above that in other portions of the transformer and rises in consequence through the working parts to the cold water pipes where it becomes cooled, after which it passes down around the outside of the core. A continuous circulation of the oil is thereby produced which results very effectually in maintaining a low temperature throughout the transformer.

The regulation of a transformer is the difference between the secondary voltages at no load and at full load, and is generally expressed as a percentage of the secondary voltage at no load. Its value is governed by the resistance and the reactance of the windings. Decreasing their resistances by employing conductors of greater cross-section, or decreasing their reactances by dividing the coils into sections and closely interspersing those of the primary winding between those of the secondary will improve the regulation. In transformers where there is a great difference in voltage between the primary and secondary windings, however, this remedy has its limitations on account of the great amount of insulation which must necessarily be used between the windings, and which therefore causes the distance between them to become such as to cause considerable leakage of the lines of force. Transformers of large capacity usually have a better regulation than those of small capacity, but in no case should its value exceed 2 per cent. In certain 1,875 kilowatt transformers recently constructed the regulation was 1 per cent.

As to the construction of transformers there are on the market two distinct types, in one of which the primary and

secondary coils surround the iron core, and in the other the core surrounds the coils. The former are known as the core type, and the latter as the shell type. The principal advantages possessed by transformers of the shell type are a larger proportion of core surface exposed for radiation of heat, and a shorter magnetic circuit which reduces the tendency for a leakage of the lines of force into the air. The primary and secondary coils are usually wound with insulated copper strap, and in some cases they are arranged one within the other, while in other cases they are placed on the core side by side. Both methods have advantages and disadvantages as compared with the other. In the former arrangement there is less magnetic leakage, but also less surface exposed for radiation and greater difficulty in providing efficient insulation between the two circuits; in the latter arrangement there is more surface exposed for radiation and less difficulty in insulating the windings, but there is also a great leakage of the lines of magnetic force into the outer air. Usually there is but one primary winding but the secondary winding is generally divided into two equal sections, the four terminals of which are permanently wired to four connection blocks which may be connected so as to throw the secondary sections either in multiple or in series with each other at will.

SOME PRACTICAL POINTS IN ARMATURE CONSTRUCTION, DEALING CHIEFLY WITH INSULATION.*

BY H. S.

This short descriptive paper was originally written to impart information to the workmen engaged in armature construction at a works with which the author is connected. It was appreciated by those to whom copies were given, and it is thought that the hints contained therein may be of interest and service to others engaged in this class of work. Possibly, also, it may be of interest to those in charge of electrical plant who have occasionally through force of circumstances to undertake their own repairs, etc., and who, from want of opportunity, have not been in a position to acquire much electrical knowledge. To electrical engineers it is, of course, elementary in character, and is not intended for their perusal. An explanation is given of various points which are important in the winding and construction of armatures. The points to which attention is directed are illustrated by sketches, and any intelligent workman will readily see what parts and places require the greatest care in insulating, etc.

Insulation from the core, spindle, and any other parts in metallic connection with the same, is equally important in every type of armature, whether it be Gramme ring, or wire-wound drum, bar-wound drum, or slotted core. It should be borne in mind that "no chain is stronger that its weakest link," and if an armature breaks down to "earth," it will do so where the insulation is thinnest or weakest, or where it is liable to be injured mechanically, and thereby weakened under ordinary running conditions. Thus, equally great care must be taken with the insulation of all parts.

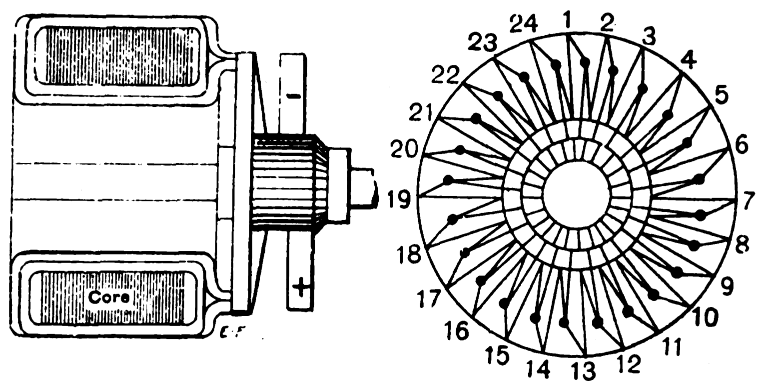

FIG. 1.

Gramme Ring Winding, showing top end of one coil and inside end of next coil joined together at the commutator arm.

The insulation of the core, etc., having been made as perfect as possible, the next point which demands attention is the insulation between the various wires or bars. It will be readily understood that the place where a short-circuit is most likely to occur—supposing that the insulation is equally good everywhere—is where the greatest difference of potential (or, in other words, the greatest number of volts) exists between wire or bars close to or touching one another. The position of these points of greatest difference of potential varies in different classes of armatures, depending on the method of winding, and a short description follows showing where these important places are situated in the various types of armatures.

Two-Pole Gramme Ring Armatures.—This form of armature winding is one of the safest from "short-circuit," for, as will be seen by reference to Fig. 1, the greatest difference of potential is between the conductors and commutator parts at opposite ends of a diameter all the way round. The greatest pressure between any two wires touching one another can only amount to a small portion of the total number of volts. Thus, if an armature is wound with 50 sections, roughly speaking each section will contribute one-twenty-fifth part of the total voltage. If the armature is to give 100 volts, it means that each coil or section will have to give 100/25 = 4 volts, so that the pressure between each section and its neighbor is very little.

Two-Pole Smooth-Core Drum-Wound Armatures.—With all drum-wound armatures the case is different. Instead of each conductor completing its circuit by returning through the inside of the core, as in the Gramme ring-winding, it passes across the end of the core and along the opposite surface, each section or coil usually consisting of one long bar attached to a commutator section and one short bar on the opposite side. Now, a commutator section opposite to the one just mentioned will also have a long bar attached to it. This long bar will, therefore, be lying near to, in fact, touching the short bar belonging to the first-mentioned section or coil. Thus it will be seen that there is the full voltage of the machine between every adjacent long and and short bar all the way round the armature. It is necessary, therefore, to insulate the long bars from the short bars very thoroughly and well, especially where the long bars pass over the "crossings" or "end connections" to which the short bars are attached, because these joints are bare. The strip of mica cloth generally employed forms an excellent means of insulating this place, but to be thoroughly effective it should be at least ½ inch wider than the leg of the "crossing," A, so as to project ¼ inch. beyond the bare metal on each side. Care should also be taken that the insulation on the long bars themselves is continued quite close up to where they join legs, B, of the "crossings." The difference of potential between each "crossing," C C, is very small, but there

*From the "Electrical Engineer," London.

is the full voltage between the inside legs, A, and outside legs, B, of the "crossings" at any point near the circumference of the armature, because the tips are attached to short and long bars, and it has been shown that there is the full voltage between long and short bars. Reference to Fig. 2 will show this clearly.

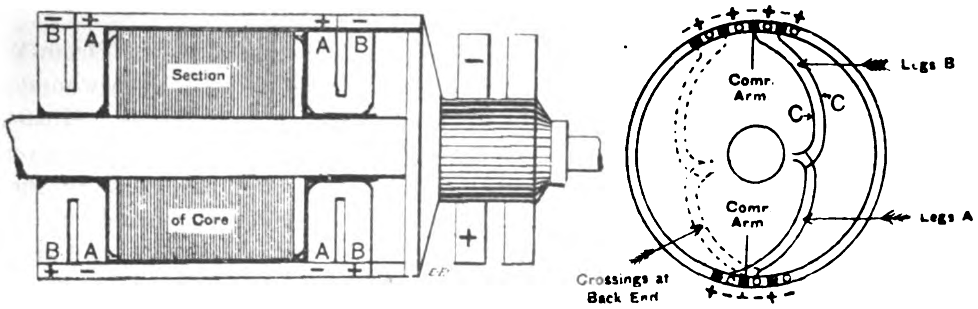

FIG. 2.—SMOOTH CORE DRUM WOUND BAR ARMATURE.

The long bars are represented by squares and the short bars by circles. What has been said above with reference to bar armatures applies also to wire-wound drum armatures, so far as the wires on the surface of the core are concerned, but the case is somewhat different at the ends of the core. This point, however, will receive attention when dealing with slotted-core armatures.

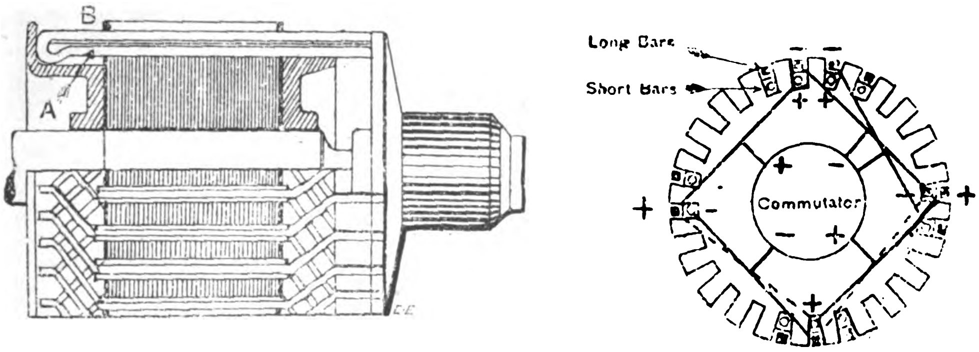

FIG. 3.—FOUR-POLE SLOTTED-CORE BAR ARMATURE WITH BARREL WINDING.

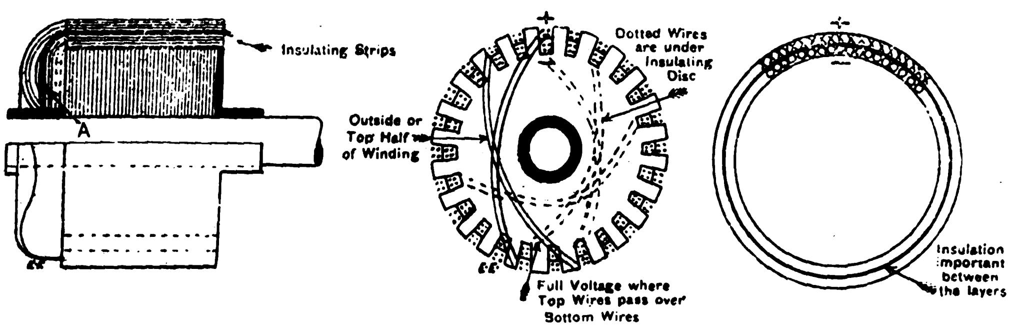
Slotted-Core Drum Armatures.—In slotted-core armatures the full voltage usually occurs between the top and bottom bars in any slot or top group and bottom group of wires. In this method of winding the top and bottom conductors correspond to the long and short bars of a smooth-core armature, and all that has been explained previously in paragraph 5 applies to this type of armature, bearing in mind that the great need for insulation is between top and bottom bars. In four-pole and multipolar armatures it is often more convenient to adopt the so-called "barrel" type of formed coils instead of using separate crossings. When such coils are used, there will be the full voltage between the top part, B, of the barrel end connection and the bottom part, A, at any point close up to the end of the core, these points corresponding to leg A and B of the ordinary crossings. It is most important, therefore, to have a sheet of good insulating material in the space between A and B, espcially close up to the end of the core. Fig. 3 will explain this clearly.

In a wire-wound armature with slotted core great care must be taken with the insulation between the bottom group and top group of wires. The strip of insulating material should project beyond the core at each end, so that it may be bent down to partially cover the wires of the bottom coil in the slot, where they emerge from the core. Some extra insulating material, such as varnished paper or calico, is desirable between each coil on the ends of the armature, but it need only be thin. When the first half of the coils has been wound, both ends of the armature should be thoroughly well insulated before any of the second half is wound, as there will be the full voltage at various points on the ends between the first half and the second half of the winding, in the same way that there is between the inner and outer legs of the "crossings" of bar armatures. In the case of armatures with a double winding and two commutators, the above remarks apply, of course, to each of the windings, and in addition, specially great care must be taken to thoroughly insulate the second winding from the first, both in the slots and on both ends.



Two-Pole Slotted-Core Wire-Wound Drum. A is a disc of insulation put on the ends as soon as one-half the total number of coils has been wound.

Smooth-Core Two-Layer Drum Winding.

FIG 4.

The points mentioned with regard to wire-wound slotted-core armatures apply also to the special form of wire winding sometimes used for smooth-core armatures, where the conductors are all laid round the armature core at the start, while the ends of the armature finally form a sort of hollow cage or barrel. The full difference of potential occurs between the first and second layers in a two-layer winding, due to the method of connecting up, and not between wires side by side as in a bar armature.

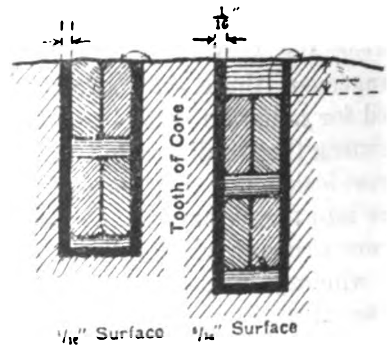


FIG. 5.

A few words on the importance of leaving sufficient surface of insulation for prevention of breakdowns. Although many materials are such good insulators that even very thin pieces will withstand a pressure many times greater than the working voltage, however good the material may be, there is always the danger that an accumulation of moisture or dirt, such as copper or carbon dust, may lead the current across a narrow surface from one place to another, say, for instance, from a long bar to a short bar, and thus a short-circuit, the effect, of course, being quite as bad as though a spark had passed clean through the insulation between them. A reference to Fig. 5 will show exactly what is meant. For an example, a bare copper bar is shown in a slot of an armature, being insulated from the core by a trough of mica, presspahn, or any

suitable material. If this trough is, say, only $\frac{1}{16}$ inch thick, it may take a pressure of thousands of volts to pierce through it, but if the bar is flush with the top of the trough, and a small amount of grease or dust happens to cover the edge of the trough, very likely only a few hundred volts would be sufficient to spark across this $\frac{1}{16}$ inch surface.

Now, suppose that instead of the copper bar being flush with the top of the trough, it is considerably below, say $\frac{1}{4}$ inch, there will now be a total length of service of $\frac{5}{16}$ inch to bridge across with dirt before any harm could result. And as in practice this open top of the trough would be filled in with a tightly fitting strip of insulating material, there would be very little chance of any dirt bridging across. This is the reason for making the strip of mica cloth $\frac{1}{2}$ inch wider than the leg of the crossings in a drum-bar armature, as mentioned previously. This point of "surface leakage" is very important.

In conclusion, it may be once more stated that neglect of these precautions at any single point is certain to result in a breakdown sooner or later. It is hoped that this short paper may be the means of showing workmen the reason why, as well as how, certain things in armature construction are done.

COIL WINDINGS FOR ELECTRICAL PURPOSES.*

BY RICHARD VARLEY AND CHARLES R. UNDERHILL.

The electro magnet as a temporary power transformer has long been in general use for various purposes and has now reached a stage where it can be standardized for performing a certain amount of work through various distances. As there is very little data on the subject and the requirements are so exacting, the practical method of obtaining data is to construct electro magnets of different forms and sizes and make actual tests, and having once found the pull which may be produced through various distances with different magnetizing forces, it is then comparatively easy to determine what size of wire should be used for any given voltage to produce the desired results.

To begin with, the first data usually given is the tractive force, or the amount of pull required. The next is the distance through which this force must act. This gives the total amount of work in foot pounds. The time factor does not enter into the work so much in a case of this kind, but the time that the current is to be left on the winding does determine the size of the winding, particularly the outside diameter, as the winding must have sufficient superficial area to radiate the heat rapidly enough to prevent the winding itself from becoming overheated. If the area is not sufficiently great, the heat will not have sufficient outlet, so to speak, and therefore the winding will get extremely hot, which heating not only raises the resistance of the winding, thereby decreasing the ampere turns for a constant voltage, but it is also liable to damage the insulation, thus causing a short circuit, and, in consequence, a complete burning out of the coil.

In studying the many phases of electro-magnets very interesting points are noticed. For instance, for long ranges the pull will vary almost in direct ratio to the ampere turns, while for short ranges, that is, where there is a short gap in the circuit, the proportionate pull will be much greater for low magnetizing forces than for high magnetizing forces. The reason for this is obvious. In the case of a long range, the iron will not become sufficiently saturated to increase the total reluctance of the magnetic circuit, as the reluctance of the air gap is at least 90 per cent. of the total reluctance. In the case of the short air gap, however, and particularly if the sectional area is great, the reluctance of the gap may not exceed, or in some cases may be less than the reluctance of the iron portion of the magnetic circuit, therefore it is very difficult to make any set rule for determining the pull.

Again, there has been very little data published regarding the coil and plunger type of magnet, or solenoid. General magnetization curves have been shown, but no particular working data given, therefore the manufacturer of electro-magnets has to make a great deal of original research in order to be able to make estimates on electro-magnets specified under many varying conditions. It has been found that by making different sized magnets of various types that a general curve may be drawn by reference to which the proper dimensions may be found for any pull through any range desired.

The data required from customers ordering is as follows:

The pull, whether uniform or accelerating.

The distance through which the pull must act.

The time the current is to be on the magnet, and

The length of time between the contacts operating the magnet.

It should also be specified whether the magnet is to be in a vertical or lateral position, unless the weight of the armature is to be counterbalanced by a weight or spring. When this is not specified, it is customary for the manufacturer to make the pull of the magnet great enough to include the weight of the armature. It is important to know the length of time the current will be on the winding in order to make the radiating surface sufficiently great, and also to know the length of time between the contacts, as the magnet will cool during that time, and so that this may be deducted from the heating.

Again, there is little data given which enables the designer to actually determine just how much a magnet will heat with a given voltage or current, and this again has to be practically determined from actual tests. By these means a standard line of electro-magnets and solenoids has been designed, standard patterns made, etc., which enables the customer to obtain exactly what he wants at market prices, just as he purchases a dynamo or motor.

There is no good reason why the customer should not be able to obtain an electro-magnet to perform any reasonable operation, and this on the open market, just as he would obtain a dynamo or motor.

As an example, let us assume that an electro-magnet is required which will pull 25 pounds through a range of 10 inches.

Now, since the field of the solenoid is nearly uniform throughout its entire length, the solenoid immediately suggests itself for this purpose.

But here the designer lacks data on the relation between the ampere turns in the winding and the necessary diameter of the plunger in order to fulfill the specifications. The practical way out of this difficulty is to make a test. By selecting several lengths of solenoids with different diameters, and by testing these solenoids with various sizes of plungers, excellent data is obtained which helps the designer to determine the proper size of solenoid and plunger for any specific purpose.

It is obvious that an iron-clad solenoid is stronger than the simple type of solenoid, as the iron completes the magnetic circuit. But here again the designer lacks data, and therefore tests must be made before the actual design can be completed.

Again, the plunger electro-magnet is much stronger than the simple or iron-clad solenoid, for short distances, as it has the combined functions of the iron-clad solenoid and the electro magnet, and data has to be obtained for this. So it is for all the different types of electro-magnets. True, we have excellent data for

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

electro-magnets with closed magnetic circuits, but it is a rather difficult undertaking to accurately calculate the action of an electro-magnet when its range of action is comparatively great.

The pull does not vary by any known law, such as the square of the distance, or the cube, for that matter, but the pull is much greater when the air gap is small than when the air gap is great, although in the latter case the pull is more uniform for a given range.

Where the air gap is small, the iron portion of the magnetic circuit may also be short, as less electrical energy is necessary to produce sufficient magneto-motive force to send the required amount of flux across the gap. In all cases the magnetic circuit should be as short and as large as possible in cross section, but for long air gaps much more room is required for the winding necessary to force the lines through the large air gap, i.e., a winding of higher pressure is required, and where the reluctance of the air gap is great the reluctance of the longer iron portion of the magnetic circuit will be negligible by comparison with the reluctance of the gap. The time that the current is to be in the winding also determines the size of the winding, as a winding, which is to be in circuit only momentarily, will not require as much radiating surface, and therefore a much larger wire may also be used, thereby reducing the size of the winding for the same ampere turns.

To the casual observer, the winding of an electro-magnet is the least important of that indispensable detail of so many electrical devices. The magnet circuit is carefully considered, as it should be of course, but the winding is briefly referred to in terms of ampere-turns. This is correct, so far as it goes, but how about the economy of that winding? How shall the winding itself be so constructed that the maximum of magnetic energy in ampere-turns may be obtained with the minimum amount of electrical energy?

The ampere-turns are, of course, dependent upon two things only, namely, the resistance of the average of all the turns in the winding, and the electromotive force applied to the winding.

This rule is based upon the following reasoning: Assume a single layer of insulated wire wound upon a core of any given diameter. Now assume but one turn of wire, with, say, one volt pressure on that turn. If the resistance per turn of wire is .01 ohm, the resultant current would be 100 amperes, therefore for one turn of wire there will be 100 ampere-turns. Now assume two turns of wire with the same total pressure, i. e., one volt. The resistance will then be .02 ohm, and the current 50 amperes. Then 50 amperes and 2 turns equal 100 ampere turns as before. This rule holds the same for any number of turns, only in the practical condition the average diameter of all the turns is taken.

As the current strength for a constant resistance is dependent upon the voltage, in the case just considered the ampere-turns for 10 volts would be 10 times the ampere-turns per volt, or 1,000 ampere-turns. Therefore it will be seen that the ampere-turns, for any specific case in which the voltage and mean diamter of the winding are given, depend entirely upon the resistance of the average turn regardless of any number of turns in the winding.

The economy of the winding for any specified number of ampere-turns depends entirely upon the number of turns in the winding, as the greater the number of turns for the same mean diameter, the greater will be the resistance, and consequently the less will be the current for the same ampere-turns and voltage.

The meaning of this is, that less electrical energy is required to maintain a given magnetizing force in a coil with many turns of a given size of conductor, than with a few turns of the same conductor.

The ideal condition would require a wire whose cross-section should be square or rectangular, and the insulation should be vanishingly thin, that is, the convolutions should be insulated from one another, without any space being occupied by the insulation. The practical conditions, however, are far from being ideal, not only with respect to the exceedingly thin insulation, but also on account of the infeasibility of using wire of square or rectangular cross-section, owing to the perversity of the square wire in endeavoring to rest upon its corners in the winding, instead of upon its flat sides, as is assumed in the idea case, and while the rectangular wire or ribbon answers very well for heavy work, it does not give satisfactory results with wires finer than No. 14, on account of the greater amount of insulation required to cover it for equal cross-sections as compared with round wire and for this reason best results are at the present time obtained with round wire.

The ordinary method of insulating is to wrap cotton or silk about the wire. For all practical conditions cotton is quite as good for insulating as silk, but owing to the greater thickness of the cotton, the silk covered wire winding is more economical as to operation, although a trifle more expensive in first cost.

Let us compare the various weights of copper in the ideal case with the weights of copper in the windings with silk and cotton covered wire.

In the ideal case the winding volume would be entirely filled with copper, while in the practical cases the volume occupied by the insulation as well as the volume lost due to the interstices between the turns of round insulated wire, must be deducted from the total winding volume to give the volume of the copper.

For this purpose let us consider a winding volume of one cubic inch. For the ideal condition, the weight of the copper would be .03 pound, while for a No. 30 B. & S. wire insulated with silk to 2 mils increase, the weight of the copper should be but .175 pound, and for a cotton insulated wire of the same diameter, the increase in diameter, due to the cotton, being 4 mils, the weight of the copper in the winding would be but .129 pound.

It is sometimes desirable to use an insulating material which will not burn when the winding becomes very hot, and asbestos covered wire is used to some extent, especially in arc lamps where the temperature of the controlling magnets is influenced by the heat from the arc, but while this insulation is not inflammable and does not char or crumble, it is so thick that only a small portion of the available winding volume is filled with copper, and for this reason the asbestos insulated wire is not economical, as compared with cotton covered wire.

In the calculation of the proper wire to be used in a given bobbin for any specific purpose, there are two factors which must always be determined. One is the resistance factor and the other the space factor. These two factors may be combined and called the combined space and resistance factor, and expressed in terms of "ohms per cubic inch." Therefore if we know the cubical contents of our bobbin, and have previously calculated a table of "ohms per cubic inch" for the various sizes of insulated wire, we may quickly determine the proper size of wire for our purpose.

Let us consider a round winding. Since the winding on a bobbin of circular section is really a hollow cylinder the volume will be

$$\pi L\left(\frac{D^2 - d^2}{4}\right) \text{ cubic inches.}$$

Where D = outside diameter of winding,
d = inner " " "
L = length " " "

(To be continued.)

THE INSTITUTE BANQUET.

The annual dinner of the American Institute of Electrical Engineers, and the fifty-seventh anniversary of the birth of Thomas A. Edison, called together a large assemblage—nearly 700 persons—at the Waldorf-Astoria last Thursday evening.

The ballroom of the hotel was strung with wires, and telegraph instruments were scattered all over the place. Chief among the decorations was the incandescent light.

The first announcement of the evening was made by President Arnold, who said:

Ladies and Gentlemen: I have the following message from the President: "Thomas A. Edison, Waldorf-Astoria, New York. I congratulate you as one of the Americans to whom America owes much, as one of the men whose life work has tended to give America no small portion of its present position in the international world—Theodore Roosevelt."

The reading of the telegram was received with great applause and a standing toast was drunk to the President of the United States.

President Arnold—In opening the intellectual part of the evening's programme, I cannot perhaps interest you more, and better lay the foundation for what is to follow than by first directing your attention to the objects for which our Institute is organized, the requirements for membership in it, and refer to the achievements of its members in general, for to others fall the pleasanter task of testifying to the specific work of our distinguished guest of honor. (Applause.)

President Arnold then gave a brief history of the Institute, and concluded his address by introducing Mr. T. Commerford Martin, the toastmaster.

Mr. Martin made a felicitous speech and proposed the health of Mr. Edison, which was drunk and cheered, the band playing "For He's a Jolly Good Fellow."

Mr. Edison responded to the toast by telegraph, rapidly ticking out his speech on a Western Union Edison quadruplex, his original invention. It was received at the other end of the banquet table by A. B. Chandler, President of the Postal Telegraph Company on a Postal "quad" and then read amid uproarious applause.

Mr. Edison, while sending his speech, sat with a cigar in his mouth, and was all smiles. The following was his response:

"I want to thank first of all my fellow members ot the American Institute of Electrical Engineers for the great honor done me in thus celebrating my birthday, associated with the twenty-fifth anniversary of the completed development and successful introduction of the incandescent lamp. Your expressions of good will gratify me deeply. While I cannot but rejoice at the place which the incandescent lighting art has made for itself among the inestimable comforts and conveniences of civilization, I feel that my share in the work is exaggerated by this prominence given me to-night.

"To my old friends and associates who have founded the Edison Medal in the Institute I can but extend you thanks again. If I could do it in return I would found a medal for every one of you, for you are just as much entitled to recognition as I am. You gave me your friendship and loyalty, your watchful days of toil and sleepless nights of anxiety. Some of you helped to perfect the art by your engineering skill, your legal ability, your financial aid."

Mr. Samuel Insull, representing the Edison Medal Association, presented to the American Institute of Electrical Engineers, as trustee, the fund raised to found and endow an Edison Medal to go each year to that student in electrical engineering whose thesis or recorded research shall be deemed most worthy of honor.

Happy speeches were made by Dr. Kennelly, Prof. Pritchett and others, and during the evening the telegraph instruments in the banquet hall were kept busy recording messages of congratulation to Mr. Edison from all parts of the world.

PERSONAL MENTION.

Mr. John H. Kelman, formerly superintendent of the Stanley Electric Manufacturing Company in Pittsfield, Mass., has resigned his position to take one with the Allis-Chalmers Company of New York, manufacturers of heavy machinery.

Mr. R. B. Strong and **Mr. A. C. Middleton**, announce that they have formed a co-partnership under the firm name of Strong & Middleton, as consulting electrical engineers, located at 39 Cortlandt street, this city.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 9, 1904.

Electric Railways and Appliances.

751,456. Surface-Cleaning Device for Third Rails of Electric Railways. Milton C. Canfield, Cleveland, O., assignor to the Stanley Electric Manufacturing Company, Pittsfield, Mass. Filed Jan. 14, 1903.

751,749. Trolley-Wheel. John E. Palmer, Somerville, Mass. Filed Nov. 14, 1903.

751,835. Electric-Car Truck. Edward Cliff, East Orange, N. J. Filed Nov. 21, 1903.

751,900. Trolley Road-Crossing. James M. Collins, Byesville, O., assignor to Joseph A. Jeffrey, Columbus, O. Filed Feb. 2, 1901. Renewed Sept 9, 1903.

Electric Lights and Appliances.

752,005. Electric-Arc Lamp. Frederick Sindingchristensen, Brooklyn, N. Y., assignor of one-half to Francis F. Storm, Maywood, N. J. Filed Aug. 29, 1902.

Electrical Machinery and Apparatus.

751,440. Commutator-Lead and Mode of Making Same. Charles F. Adams, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed Aug. 8, 1903.

751,442. Reverse-Current Cut-Out. Leonard Andrews, Manchester, Eng., assignor to the Stanley Electric Manufacturing Company, Pittsfield, Mass. Filed June 25, 1903.

751,474. Pole-Changer for Dynamos. Isidor Deutsch, Montreal, Canada. Filed May 14, 1903.

751,540. Power-Transmitting Mechanism. David L. McClintock, Kansas City, Mo. Filed April 27, 1903.

751,547. Motor-Controller. Francis V. Nicholls, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed June 13, 1903.

751,563. Dynamo-Electric Machine. David B. Rushmore, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed June 26, 1903

751,571. Time-Limit Relay for Electric Circuits. Harve R. Stuart and Arthur B. Reynders, Wilkinsburg, Pa., assignors to the Westinghouse Electric & Manufacturing Company. Filed April 11, 1903.

751,574. Electric-Spark-Producing Apparatus. Chester H. Thordarson, Chicago, Ill. Filed March 10, 1903.

751,581. Controlling Mechanism for Electric Vehicles, Frank S. Wahl, Buffalo, N. Y. Filed Dec. 21, 1901.

751,595. Parallel-Feeder Protection. Leonard Wilson, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed July 16, 1903.

751,597. Electric Switch. Gilbert Wright and Harold C. White, Pittsfield, Mass., assignors to the Stanley Electric Manufacturing Company. Filed June 13, 1903.

751,598. Means for Controlling Governor-Motors. Gilbert Wright, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed Sept. 24, 1903

751,616. Magneto-Electric Generator. Hugh J. Creighton, Anderson, Ind. Filed May 13, 1903.

751,634. Rheostat. George Graybill and John P. Oden, York, Pa. Filed June 8, 1903.

751,654. Apparatus for the Regulation of Electrical Circuits in Heating Devices. Willie D. Kilroy, Uxbridge, Eng. Filed Oct. 6, 1902.

751,854. Thermostat. George D. Hoffman, Chicago, Ill., assignor to the Norwall Manufacturing Company, same place. Filed May 25, 1903.

751,903. System for the Operation of Electric Motors. Arthur C. Eastwood, Cleveland, O. Filed Sept. 25, 1903.

751,985. Underground-Conduit Insulation. John M. Humiston, Berwyn, Ill. Filed April 27, 1903.

751,991. Current-Director. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company. Filed Jan. 28, 1901.

751,993. Speed-Regulator for Generators. George J. Pelstring, Cincinnati, O., and Henry G. Pelstring, Covington, Ky. Filed May 11, 1903.

752,008. Induction-Coil. Charles F. Splitdorf, New York City. Filed July 15, 1902.

Telephones and Telephone Apparatus

751,501. Electric Telephone. Ernest Gundlach, Western Springs, Ill. Filed Nov. 10, 1902.

751,539. Ringing-Key for Telephone-Switchboards. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company. Filed May 9, 1902.

751,566. Ringing-Key for Telephone-Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company. Filed May 9, 1902.

751,797. Central-Energy Telephone System. John H. Lendi, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Dec. 19, 1900.

751,829. Telephone. Ernest T. Billig, New York City. Filed Dec. 2, 1902.

751,845. Telephonic Repeater. Merritt Gally, Brooklyn, N. Y. Filed April 23, 1903.

Miscellaneous.

751,441. Means for Protection Against Reverse Currents. Leonard Andrews, Manchester, Eng., assignor to the Stanley Electric Manufacturing Company, Pittsfield, Mass. Filed June 25, 1903.

751,459. Line-Insulator. Cummings C. Chesney, Pittsfield, Mass. Filed Jan. 14, 1903.

751,460. Lightning-Arrester. Cummings C. Chesney, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed Aug. 8, 1903.

751,549. System of Electrical Distribution. John S. Peck, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed May 1, 1903

751,569. Altiscope or the Like. Lawrence Y. Spear, Greenport, N. Y., assignor to the Electric Boat Company. Filed March 14, 1903.

751,655. Telephony. Isidor Kitsee, Philadelphia, Pa. Filed Jan. 9, 1901.

THE TELEPHONE WORLD.

Independent Telephone Merger in Indiana.

The officials of the 14 Independent telephone companies in Henry County, Ind., recently met in New Castle, for the purpose of perfecting an organization which will have for its purpose the general extension of county lines, mutual benefit, hearty co-operation, and all will unite in an effort to fight competition introduced by the Central Union people. The meeting was held behind closed doors, and the proceedings were not given for publicity.

Telephone Company Gives Free Service in Chicago.

Subscribers to the Illinois Telephone, the new automatic service in the downtown district, have received a pleasant, unusual and unexpected surprise. Official announcement was made by the Illinois Tunnel Company, successors to the telephone corporation, that all bills for past service will be wiped out and that service on the telephones now in use or to be put in will be free up to April 1, 1904.

This action wipes out bills or charges at the rate of 5 cents for every call made since the installation of the system. President Wheeler said in explanation of the announcement:

"We now have almost 5,000 telephones in use and are adding to the number daily. We want to educate the people in this business men's exchange to the great value of the service, and in order to get our subscribers and the public generally to use the telephone freely, we decided to wipe out the charges for all past service over our lines and continue the free service up to April 1, 1904. It is a change of policy inaugurated by the Illinois Tunnel Company, and I believe it is the first time anything of the kind was ever done by a public service corporation in this or any other country."

The stockholders of the Plattsmouth, Neb., Telephone Company held their annual meeting a short time ago and the usual 10 per cent. dividend was declared. The following officers were elected: President, T. A. Parmele; vice-president, C. C. Parmele; secretary, J. N. Wise; treasurer and general manager, T. H. Pollock.

Kansas City, St. Louis and Nevada are to be connected by a telephone line which is being installed by the Kinloch Company of St. Louis. The line is to start from St. Louis, through Nevada to Joplin, thence to Kansas City. Its estimated cost is $1,500 a mile. It will be one of the most expensively equipped in the State.

The Interurban Telephone Exchange Company has filed an amendment to its articles changing its place of business from Holmes City to Alexandria, Minn.

The Baraboo, Wis., Telephone Company, by its president, Charles Gorst, and secretary, August F. Fisher, lately filed an amendment to its articles of incorporation, increasing its capital from $30,000 to $50,000.

The Rollag, Minn., Telephone Company has been organized with a capital of $25,000, to do business in Clay, Wilkin, Becker and Otter Tail Counties.

Organizing to Fight the Bell Company.

E. M. Cranford of the firm of Cranford Mercantile Company is about to organize a company, with a capital stock of $2,500, for the purpose of putting in a telephone system at Jasper, Ala. The name of this new corporation will be the Home Telephone Company, and the subscribers to the capital stock will be local business men. Mr. Cranford has met with much encouragement and there is little doubt that the company will be incorporated within a short while.

The Southern Bell Company recently acquired possession of the properties of the Jasper Telephone Company, and it was believed that the rates charged for instruments would be reduced, prices hitherto having been considered excessive. But no reduction has been made in the rates, and it is chiefly for this reason that the new company is being organized. It is the aim of the new company to fix the price for its instruments in residences at $1 per month and for business houses and offices at $1.50 per month, which is exactly one-half the amount charged by the Bell Company.

The enterprise is meeting with the approval of many of Jasper's citizens, who express themselves as willing to subscribe liberally to the movement.

Ohio Telephone Deal.

A deal was completed in Cleveland last week whereby the Federal Telephone Company sold all its interest in the Citizens' Telephone Company of Columbus, O., to a syndicate headed by Cyrus Huling of the latter city. The price at which the transfer was made has not been made public, but it is known that there changed hands 3,354 shares of stock with a par value of $100. The total issue of stock was $750,000. The Columbus people bought control of the company from the Federal Telephone Company a year ago and now have completed the purchase of the stock, having it all in their hands.

The annual meeting and election of officers of the Orange and Sussex Independent Telephone Association was recently held in Middleton, N. Y. The several local telephone companies comprising the Association were represented as follows: Warwick Valley, Farmers, Highlands, Chester, Sussex, Colonial, and Orange County. The officers elected were: President, George G. Otis, of Newburgh; vice-president, George F. Ketchum, of Warwick; secretary, Mott C. Tuthill, of Washingtonville; treasurer, W. D. Haggerty, of Sussex.

The Schenectady, N. Y., Railway Company will shortly install a system of telephones on its Troy and Albany interurban lines. These telephones will be placed in the cars running on these divisions, and they will be so arranged that communication may be held with the office in Schenectady at any point along the tracks.

The Charleroi, Pa., Telephone Company has applied for rights of way through Charleroi and the petition will be acted upon at the next meeting of the council. The company was formed by local men last December and has 125 subscribers.

Signs of Telephone War.

A lively telephone war seems imminent in Shelby County, Ia. The Bell Company has been supplanted for all but long distance service by the Harlan & Avoca Company, an Independent company. In the east part of the county, however, three or four farmers' mutual lines have been in process of building, and, indeed, in use over a limited territory. These lines for some time have been endeavoring to secure what they thought would be reasonable rates for connection at Harlan with the Harlan & Avoca Company. Failing in this, about a dozen representative farmers recently appeared before the Harlan city council and presented a written petition backed up by oral argument for a franchise allowing them to come into Harlan. The farmers offered to pay the expenses incident to the submission of the proposition to the people. The city council passed a resolution providing for the submitting of the question next spring at the regular election. The farmers' lines have several hundred 'phones in operation, and they will wield a large amount of influence with residents of Harlan.

At a recent meeting of the grocers and butchers of Clare, Mich., it was decided to throw out all Bell 'phones and use the Union or Independent 'phone exclusively. This is counted as quite a successful outcome of the Independent and Bell Companies' fight that has been put up in Clare during the past week, although the movement started by the merchants in that city was voluntary without any agitation on the part of the telephone companies.

Telephones were lately installed in Missouri on the cars of the suburban divisions of the East St. Louis & Suburban Electric Railway, which permits the street car employes to connect with the power house or the general superintendent's residence from any point along the lines. The system is arranged so that on every 15th pole there are connections into which are placed the wires of the telephones, which are carried on the cars.

Arrangements are being made by the People's Telephone Company of Wayne, Mich., for an extension of the line from Carleton to Stoney Creek, about three miles southwest of Carleton, then to make connections with the line running to Scofield.

The Pittsburg & Allegheny Telephone Company is to adopt the automatic system in McKeesport, Pa., and has just completed arrangements for adding about 5,000 subscribers to its list by connecting with the National Telephone Company of Wheeling, W. Va.

Telephone Incorporations.

The Consolidated Telephone Directory Company, Cleveland, O. Capital stock, $15,000. Incorporators; C. I. Werlenbaker, B. F. Bellows, J. B. Beardsley, V. F. Bellows and L. N. Wertenbaker.

The Kelsey Telephone Company, Kelsey, N. Y. Capital stock, $2,000. Incorporators: George Webster, Anna Thompson and J. H Alexander.

The Atwater Telephone Company, Atwater, Minn. Capital stock. $10,000.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Albuquerque, N. M.—It is understood that the Santa Fe Company will overhaul its electrical plant in this city.

Benton Harbor, Mich.—The council has closed a contract with the Benton Harbor & St. Joseph Electric Light Company for lighting a certain part of this city for a term of years.

Burlington Junction, Mo.—Robert Crooks contemplates the erection of an electric light plant here.

Cloverport, Ky.—The city clerk has been ordered to advertise for bids for electric lights in this city.

Dayton, Tenn.—A proposition to establish an electric light and waterworks plant is being considered by the mayor and board of aldermen of this city.

Dewitt, Ia.—The Dewitt Electric Light Company will expend several thousand dollars in improvements.

Dyersville, Ia.—The Dyersville electric light plant has been sold to Eastern capitalists, who will enlarge the plant.

Ellensburg, Wash.—A recent election here resulted in favor of issuing $20,000 worth of bonds for the purpose of constructing an electric light plant.

Ft. Worth, Tex.—George F. Majars and T. A. Holdes, local capitalists, are preparing to erect an electric light plant here.

Georgetown, Ill.—The village board has granted a franchise for the electric light plant for this village, which must be completed within nine months.

Henderson, Tenn.—The local electric plant has been purchased by a Mr. Dalton of Huntingdon, Tenn., who will reconstruct it.

Hope, N. J.—There is some talk of an electric light plant for this place.

Hopkins, Mo.—C. M. Hartness is figuring on the cost of an electric light plant for this place.

La Farge, Wis.—The La Farge Electric Company has been incorporated to erect an electric light plant here. Its capital stock is $6,000. James Dinsdale, James O. Davidson and B. C. Rosencrans are the incorporators.

Lincoln, Ill.—Articles of incorporation for a company which proposes to establish a plant for furnishing gas and electricity in competition to the present company are stated to have been drawn up. Walter J. Lamb is interested.

McGregor, Ia.—The electric light plant, which was recently destroyed by fire with a loss of $11,000, will be rebuilt.

Milwaukee, Wis.—Extensive improvements will be made by the Milwaukee Electric Light Company and the Milwaukee Light, Heat & Traction Company this year. Improvements will cost about $200,000.

Morelos, Mex.—Steps are being taken to establish an electric lighting plant in the town of Tancitaro near this city.

Neenah, Wis.—The Wisconsin Heat, Traction, Light & Power Company, operating an electric line between here and Kaukauna, has petitioned the council for a franchise to light the city.

New Haven, Ind.—Town Trustees Clark and Schnitker are agitating the installation of a municipal electric light plant.

Newton, Miss.—A company is being organized here with a capital of $100,000 to build a cotton oil mill, fertilizer factory, waterworks and electric light plant.

Penn Yan, N. Y.—The installation of a new municipal electric light plant here is being considered.

Piper City, Ill.—The farmers around here want electric lights.

Stanberry, Mo.—The Stanberry Electric Light Company has been incorporated with a capital of $25,000. The directors are J. T. Norman, A. C. Frisbie and others.

St. Augustine, Fla.—The installation of an electric light plant here is being discussed.

Troy, O.—The local business men are tired of the present inadequate electric light meter system and will erect an electric light plant of their own.

Watseka, Ill.—The electric street lighting contract with the city will expire October 1, 1904, and sealed bids will be received by the city for a new contract therefor until March 15. Address C. L. Abell, city clerk.

Wessington Springs, S. D.—Mr. Savage, of St. Paul, is here making arrangements with a local electric light company for putting in electric lights in this place.

Xenia, O.—D. M. Stewart and Charles Darlington are reported as interested in the formation of a new company for electric lighting.

STREET RAILWAYS.

Augusta, Me.—The Northern Maine Seaport Company, which proposes to build a line from La Grange to Belfast, has filed articles of association with the Secretary of State. The proposed road, which will be operated by electricity, will be 60 miles in length and will connect the Bangor & Aroostook with the Belfast branch of the Maine Central, traversing a territory not now supplied with railroad facilities. The company is capitalized at $360,000.

Canton, O.—John C. Welty, local counsel for the Tucker-Anthony Syndicate, owners of the Canton-Akron and allied electric and suburban lines, said that an electric line from Cleveland and Columbus is now an assured project.

Cincinnati, O.—Judge A. S. Berry is booming a scheme of an interurban electric road from Alexandria, Ky., to this city.

Clarksville, Ind.—A franchise has been granted to Peter Arland & Co., for a new electric line here.

Euclid, O.—At the meeting of the village council at Euclid Heights it was decided to advertise for bids for the construction of an electric line through a certain part of the village.

Harrisburg, Ill.—The Illinois & Kentucky Railway Company was lately granted a franchise to construct and operate an electric railroad over the highways in Saline County.

Hudson, N. Y.—The prospects are brighter for the construction of an electric road from here to Lee, Mass., or some other point in that State, where connections could be made with the electric roads which extend east and south through Connecticut and on to New York City.

La Fayette, Ind.—Next summer an electric railroad from here will enter Kankakee County, Ill.

Leon, Mex.—An electric traction system is projected in this city in the State of Guanajuato. Power will be derived from the Guanajuato Electric Light & Power Company, of which Henry Hine is president. Americans propose to build the system. H. F. Gornford of San Francisco, Cal., has gone to Mexico for the purpose of investigating the proposition.

Marinette, Wis.—H. C. Higgins, a Dixon, Ill., capitalist and former president and manager of the local street railway, says he is still considering the possibility of building a trolley line between Peshtigo and this city, for which he holds a franchise. Mr. Higgins is one of the owners of the Manitowoc-Two Rivers trolley line.

Minneapolis, Minn.—The Minnesota Central Railway Company is being organized by capitalists of this city to build an electric line from St. Paul to Duluth.

New York City.—Last week the aldermen granted to the New York, Westchester & Boston Railroad Company permission to cross 68 streets of the Bronx, below or above grade, with its proposed electric railroad from the Harlem River.

Ottawa, Ont.—General Manager Gay has confirmed the rumor to the effect that the Ottawa & New York Railway is to be operated by electricity, the change in the method of propulsion taking place during the present year. Electric engines are to be used, the power to be supplied from Ottawa, Cornwall and Massena Springs. It is anticipated that a saving in time and cost of operation will thus be effected.

Philadelphia, Pa.—It is stated that the Pottstown & Westchester Electric Railway Company, of which Winslow Mason is president, and S. M. Godfrey is secretary and treasurer, will build a 22-mile trolley between the places named, and thereby will complete a line from this city to Reading.

Port Washington, N. Y.—A representative of the Mineola-Roslyn-Port Washington Traction Company has been here lately settling all arrangements for the right of way with various land owners. It is the intention of the company to begin the construction of the road as soon as the frost is out of the ground. According to the terms of the franchise the trolley must be in operation not later than June 1.

Salt Lake City, Utah.—J. J. Burns, in conjunction with local capitalists, will build an electric road between here and Ogden.

Sharon, Pa.—The Cleveland & Detroit Navigation Company will furnish the capital for building an air-line electric railway from Cleveland to this city. The line is to be built across the country. The company expects to carry on an extensive freight business. Construction will begin the coming spring, The line will be 80 miles long.

POWER PLANTS.

Columbia, Tenn.—The Louisville & Nashville Railroad Company intends to build a large power plant and electric light plant at Bigby Creek just outside the suburbs of this city. The expenditures involved will be in the neighborhood of $12,000 to $15,000.

Kankakee, Ill.—The Kankakee Electric Railway will build a new power plant.

Lorain, O.—The Citizens' Gas & Electric Company will erect a new power plant here.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12¼@12½c.; Lake 12⅝@12⅝c.; casting, 12¼@12⅜c.

A London cable states that the copper market abroad is strong especially for electrolytic.

On Wednesday last Phelps, Dodge & Co. sold 1,000,000 pounds of electrolytic copper at 12¼c. a pound.

The American Railways Company (Philadelphia) has declared the regular quarterly dividend of 1½ per cent., payable March 15.

The stockholders of the Central District & Printing Telegraph Company, Pittsburg, have voted to increase the capital stock of the company from $10,000,000 to $15,000,000.

The Butte (Mont.) Electric & Power Company has declared a dividend of $1.50 a share on the common stock, payable March 15 to stock of record March 12.

The receivers of the Chicago Union Traction Company have borrowed $50,000 to pay the February interest on the underlying bonds of the Chicago Consolidated Traction system.

Application has been made to the New York Stock Exchange by the Brooklyn Rapid Transit Company to list $5,000,000 first refunding mortgage 4 per cent. coupon bonds of 2002.

The Canadian General Electric Company has secured a contract from the Toronto Electric Light Company for a 5,000 hp. plant. The equipment will include two 2,500 hp. Curtis turbines.

The independent telephone companies of Northern & Middle Vermont have decided to establish a trunk line from St. Johnsbury to Montpelier, thus coming into direct opposition with the New England Telephone & Telegraph Company.

The Poly Phase Ingnition System Company of New York, to manfacture electrical machinery, was incorporated at Albany on Monday. The directors are R. L. Heitzemeyer of Hoboken, N. J., G. G. Schreiber and W. R. Symmes of New York.

Stockholders of the Seaboard Air Line met in Petersburg, Va., last week, and formally ratified the loan from Thomas F. Ryan and others of $5,000,000. The meeting was the last of the formalities necessary to accept and put in operation the loan which is now effected.

The creditors of the Worcester & Southbridge (Mass.) Street Railway Company were paid by check on Monday on the 50 per cent. basis. The road will soon be sold by auction and will be incorporated under the name of Worcester, Southbridge & Sturbridge Street Railway Company with a capital of $700,000.

The Western Electric Company reports making gross sales for the year ended November 30 last of $30,250,000 against $28,626,000 for the same period in 1902. Net earnings for the year ended November 30 last aggregated $2,760,000 and dividends amounted to $920,000. The company's surplus on November 30, 1903, was $8,970,000.

If the plan, now in contemplation by the directors of the United Traction Company of Albany, N. Y., is adopted, $1,339,300 will be used for extensions and improvement of the company's lines. In view of the repeated rumors about the probability of the company purchasing one or more of the suburban lines running into Albany, this large appropriation for the purpose of extending its lines seems to be insignificant.

ELECTRICITY.

VOL. XXVI. NEW YORK, FEBRUARY 24. 1904. NO. 8.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than the Saturday preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

"Electricity's" Suggestions to be Carried Out.

In the issue of ELECTRICITY of August 1, 1900, shortly after the Hoboken fire, there appeared an article strongly advocating the use of salt water for extinguishing fires. This water and necessary pressure, the article explained, could be obtained by means of electrically-operated pumps driven by surplus electric light and street railway current.

It is good news to hear that the suggestion which appeared in this journal is now advocated by the Mayor of Greater New York and unless side-tracked will in all probability be adopted in the near future.

The Mayor's suggestion, which is heartily indorsed by the Board of Fire Underwriters, is that large mains be established throughout Manhattan, south of Forty-second street independent of the Croton water mains, these mains to be connected with electric pumping plants at various places in the business districts, the pumping plants to obtain the necessary current when need be from the power houses of the elevated and surface roads. It is pointed out that after the cost of installation of such a system the item of maintenance would be very small.

It is to be hoped the plan as outlined by the Mayor will be carried out, as it would effectually insure this city against such a conflagration as recently swept Baltimore. With the North and East Rivers to draw upon for water there would be no possibility of a shortage, whereas in case of a large fire Croton water might give out. Electrically-operated pumps could be started up almost instantaneously, whereas pumps operated by steam engines would require time. The Mayor's idea is a good one, and although it may cost some money to carry out, the system when completed will be more than worth it as a means of protection to lives and property.

Electrical Discharges to Dissipate Fog.

The United States Consul General, Richard Guenther, at Frankfort, has recently sent to the Department of Commerce and Labor at Washington a translation of an article which appeared in a German paper referring to the dissipation of fog by means of electricity.

The article refers to a lecture delivered recently by Sir Oliver Lodge before the Physical Society of London. It says:

"The great physicist Tyndall had demonstrated decades ago that a heated body, if brought into a lighted atmosphere laden with dust, dispels the dust in its nearest environment and forms a dark space around itself.

"Tyndall thought that the hot body consumed or burned the dust, in his experiment, an organic one, with coal dust.

"Twenty years ago Prof. Lodge resumed the investigations of the same subject jointly with the physicist Clark, and soon found that the explanation surmised by Tyndall was incorrect. It was found that a sort of bombardment emanated from the heated body, which kept the dust at a certain distance.

"Lodge made the still more important discovery that if he employed electricity in place of heat the dust particles acquired a polarity for forming into balls, and were thrown against the walls of the vessel in which the experiments were made. In his experiments he did not use coal dust or smoke, but an inorganic dust, namely, finely powdered magnesia. For the heated or afterward electrified body he used a wire.

"Two pieces of wire netting which were connected with the ends of an electrifying machine were put up opposite each other in a room, through which a slow current of smoke passed. After the wire nets had been electrified the current of the smoke ceased; the particles of dust balled together were driven to the wall of the room and fell to the floor. If steam was introduced instead of smoke it was converted into fine rain.

"This latter result led Prof. Lodge to several conclusions. First, it almost showed by itself how rain was formed from the clouds through electrization, a fact for which, even if it had been surmised, every proof was lacking. Furthermore, Lodge concluded it would be possible to dispel a fog cloud by electricity.

"He made his first fog-dispelling experiment at Liverpool, where he was lecturing as professor of physics.

"During a thick fog the air about the university was electrified by means of a large Wimshurst machine, the current passing through a bunch of points on top of a high mast erected on the roof of the building. In this manner it was spread as much as possible. The result was that for a radius of from 165 to 200 feet the air was perfectly clear—that is free from fog.

"At that time the scientist conceived the plan for a trial on a large scale by placing a sufficient number of stations on both sides of the Mersey and charging the air on one side with postive and on the other side with negative electricity, in order to see whether a mass of fog on the river, which almost regularly caused collisions of vessels and heavy damages in consequence, could not be dispelled.

"Although the practical benefit was apparent, Prof. Lodge did not meet with sufficient support, and his experiment had to be abandoned for lack of funds."

In the issue of ELECTRICITY of September 7, 1898, there appeared an editorial on this same subject, referring in part to an article which appeared about that time in the *North American Review* by Mr. Alexander McAdie, who strongly advocated the dispelling of fog by means of electrical discharges. That nothing practical has been accomplished during the past five or six years in this line is probably due, as intimated in the German article, to lack of funds. That money is not forthcoming for experiments in dissipating fog on a large scale is to be regretted, as the solution of probably no other problem would be more conducive to the welfare and safety of mankind. Many fatal accidents at sea and on land occur through fog, and now that there is a chance of the evil being remedied, it is to be hoped some rich philanthropist will come forward and donate a fund for this purpose.

Radium Rays and Photography.

The photographic action of radium rays was the subject of a paper recently read before the Physical Society of London. It is well known that a photographic plate by exposure to radium rays is affected in such a way that the plate develops similarly to its development after exposure to light. The experiments described in the paper are an attempt to answer the question: Are the actions the same? As far as can be seen, the final results of the actions and developments are the same, and the experiments appear to indicate that only slight differences occur in the early stages. The plates, suitably inclosed, were subjected to the rays from varying quantities of radium bromide for varying times, and the results showed that the intensity of the developed image increased rapidly to a maximum value with increase of exposure, then decreased first rapidly, and finally very slowly until a stage was reached in which there was practically no dark image formed on development. It is found that spark images are at first obliterated by radium rays which do not cause such a great density as that of the spark images obliterated, and that with prolonged exposure the radium rays reverse the spark images.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Work to aid miners in locating radium in America has begun in the Ryerson Physical Laboratory at the University of Chicago, under the direction of Prof. Robert A. Milliken.

Wm. J. Chalmers, vice-president of the Allis-Chalmers Company, states that the company has formed a coalition with several important English and European manufacturing concerns, under the name of the Turbine Advisory Council, thereby practically doubling the industrial activity of his company. The new departure will comprise the manufacture of steam turbines, hydraulic machinery, gas engines and electrical machinery.

Chief Engineer William Barclay Parsons, of the Rapid Transit Commission of New York, has been invited by the Royal Commission on London Traffic to visit England to testify before that body upon traffic problems. It is said that Mr. Parsons has decided to go, and during his absence the subway work will be in charge of Assistant Engineer George L. Rice.

A bill is before the New York Legislature providing for enlistment of five technical expert civilian electricians as engineers of heavy artillery, National Guard State of New York, for service in coast defenses. It has passed in the lower house with a fair chance, if pushed, of passing the State Senate and becoming a law.

On April 30 from the top of the Washington Monument it is expected that President Roosevelt will send a wireless telegram declaring the gates of the World's Fair at St. Louis open, when President Francis, on one of the towers of the Administration Building, will press the button putting in motion 40,000 hp. units of electrical energy.

President Candamo, in the presence of 3,000 spectators, last week formally opened the electric railway between Lima and Chorillos, South America. The stations and cars were brilliantly lighted.

A foreign contemporary states that the officials of the Paris Metropolitan Railway have decided to abandon the use of power cables carrying large currents through the train and are about to install one hundred complete equipments of the electro-pneumatic turret-type control apparatus to replace the present system. One of the chief features of the electro-pneumatic control system is that compressed air is employed for actuating the controllers on all motor cars, and that the control is effected by very small currents in wires throughout the train at the harmless pressure of 14 volts.

Engineers are already making a survey of the Central-Hudson tracks between Schenectady and Hoffmans, N. Y., which will be graded and put in the finest condition for the third-rail system speed tests. It is expected that all transportation records will be beaten, and that the experiments will commence in the early spring.

Commissioner General Alexandrovsky has officially announced the abandonment of the proposed participation of Russia in the St. Louis Exposition, and it is now stated that Mr. Hajimeota, assistant commisioner general from Japan, has announced that every foot of exhibit space that is given up by Russia will be applied for by Japan.

SIEMENS & HALSKE PRINTING-TELEGRAPH CENTRAL STATION IN BERLIN.

BY FRANK C. PERKINS.

The printing-telegraph central station in Berlin, Germany, is equipped with the type-printing telegraph system of Siemens & Halske Actien-Gesellschaft in connection with the telephone service of the city which has about 70,000 subscribers. The illustration, Fig. 1, shows one of the machines which is used as either a transmitter or receiver, as well as two group switches. In Fig. 2 may be seen the printing-telegraph station, while Fig. 3 is a view of the printing telegraph. It will be noted that there are four rows of keys with seven in each row making a total of 28 in all. All but two of these keys serve the letters, figures and punctuation marks, the letters being transmitted by moving the letter shift key, and the figures and punctuation marks by moving the figure shift key, which displaces the type wheel automatically on its shaft so as to bring the circular row of figures or punctuation marks above the printing surface of the paper ribbon. Then by moving a key for a certain figure, the type wheel is rotated and brings the desired type with that figure in front of the paper, which is pressed against the type wheel, printing the figure and is returned downward quickly, ready to receive the next figure or punctuation mark. For writing the letters the letter shift key is first moved and then any of the keys of the letters desired.

One of these machines is used as a transmitter at one central station and another of the same type as a receiver at the other station. The moving of a given key on one machine causes a corresponding movement at the receiving station, regardless of whether an operator is at hand or not. If no one is at hand at the receiving machine the message is printed on the paper ribbon and may be read later.

It will be noted that with this German apparatus a copy of the telegram is made upon paper by both the transmitting and the receiving instruments which may be kept as records. In the various large cities in America as well as in Europe printing telegraph systems have been in operation for some time where a large number of receiving instruments have been controlled from one transmitter in a central station, supplying reports from stock exchanges as well as other news. A storage battery of 12 cells is used as a working battery, only 12 volts being employed on the line circuit and only one-half of the battery being employed at a time.

The German printing telegraph shown in the accompanying illustration is somewhat similar in operation to the Baudot & Hughes type printing machines. The into the printing circuit and the relays of the instruments and both the receiving and the transmitting machines are energized by local currents. These local currents cause the type wheel to rotate by means of the relay magnets through the

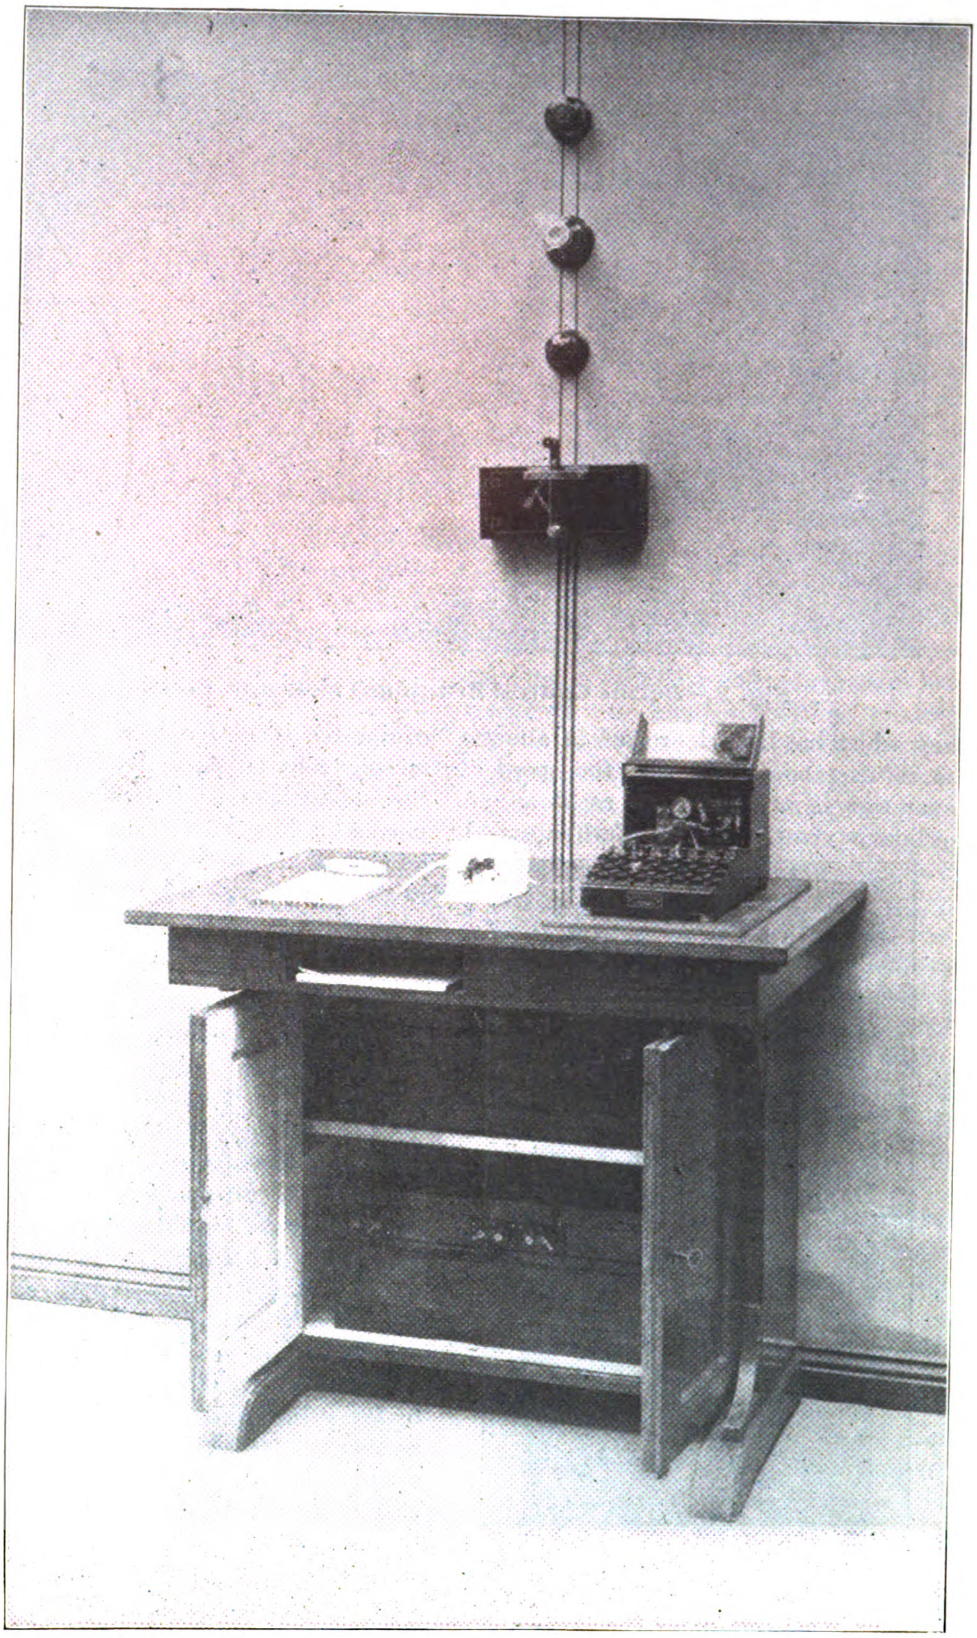

Fig. 1.—Siemens & Halske Printing-Telegraph Instrument and Two Group Switches.

circuit of the transmitting apparatus is closed when the key of a certain letter or figure is pressed, and a switching roller is rotated. Electric currents are thus sent same distance in all the receiving instruments. If a figure key is moved a projection on one end of the lever strikes against the switching inking roller which

is rotating and stops it as well as the type wheel. The type levers of both machines are attracted at the same time and the proper figure will thus be printed. The type wheel can only move again when the scriber presses his calling key, and he is placed in communication with the party desired, by the operator in charge who obtains this information by an inquiring apparatus reserved for the purpose. The

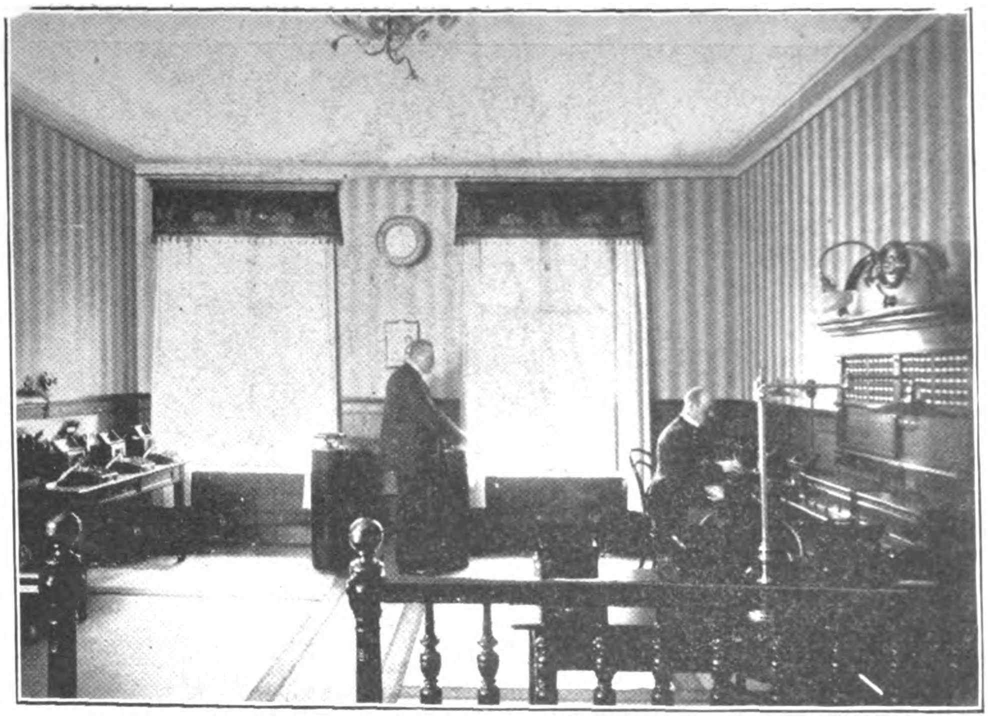

Fig. 2.—Berlin Central Printing-Telegraph Station.

key which has been depressed is allowed to return, and it is stated the speed of operation is practically as rapid as an ordinary typewriter. The Berlin Central

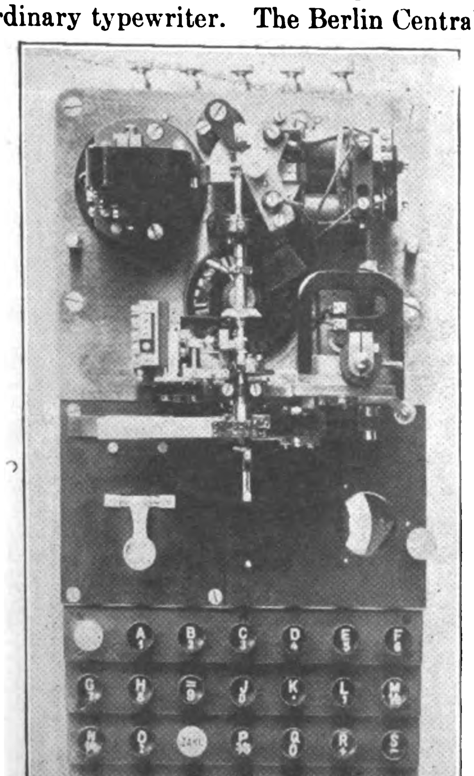

Fig. 3.—Siemens & Halske Type-Printing Machine.

Station is provided with a switchboard somewhat similar to telephone central stations with indicators for a large number of subscribers. An indicator drop falls and a bell rings as soon as any subscriber presses his calling key, and he is placed in communication with the party desired, by the operator in charge who obtains this information by an inquiring apparatus reserved for the purpose. The equipment is so arranged that the same message may be sent simultaneously to all the subscribers, as "tickers" are employed in New York, London and other cities, and also for supplying news items to all of the large newspaper plants for publication.

THE EXCITATION OF ALTERNATORS.*

BY F. H. DAVIES.

The excitation of alternators may be effected in three ways—viz., by aid of a small direct current dynamo coupled to each separate alternator shaft either rigidly or by belting; by independently-driven dynamos, sometimes combined with battery plants and used for exciting all the fields in parallel; or by variations of either of the above methods—effected by the aid of sundry connections that will be shown later—which cause the alternator to become to a certain extent self-exciting, and able to automatically compensate for variations in load in a manner similar to the compound-wound direct-current dynamo, or, in addition to this, to also compensate for variations in power factor.

The first method is, perhaps, the oldest, and has a few points that commend it, notably those of low first cost and compactness, and for these reasons it is still very greatly employed where capital and space are considerations. As regards efficiency in working, however, there are one or two defects in this system that show up both when the alternator thus excited is running singly and when in parallel with others. In the former case the voltage regulation is apt to be very bad, owing to the speed of the engine affecting both the alternator and its exciter in a like manner. If through any cause, such as a sudden increase of load, the speed drops, the alternator volts naturally drop also, both owing to the reduction in speed and the increased load; with separate excitation the matter would end here, but under this system such is not the case; the reduced speed also lowers the EMF. of the exciter, which now, of course, passes less current through the alternator field, and the consequence is a very bad drop in volts for a comparatively small decrease in speed. The converse of this is naturally true, as a small increase in engine speed produces a disproportionate rise of pressure in the alternator. The voltage regulation in an alternating-current station is always more or less of a trouble, but with this system it at times amounts to a positive nuisance if the steam pressure or load is at all variable.

This method of excitation also lends itself to satisfactory regulation when working in parallel; it means that the field rheostat of each machine must be moved separately, thus running the risk of setting up an idle and wasteful current between the alternators owing to the difference in pressure at their terminals, or, that all the regulating switches must be geared together by some more or less clumsy arrangement, the scope of which is necessarily limited to a few machines by the strength of the man that has to operate it. Modern practice confines this method to small installations, anything large being carried out upon the lines of the second one mentioned—viz., that of independently-driven exciting plant. In this system two or more separate direct current sets supply current at the right voltage to a pair of exciter 'bus bars, from which cables are led to the field switch, regulating resistance, and field coils of each alternator. The great advantage is good voltage regulation, seeing that the exciter volts are constant and small speed or load variations do not tell much upon the alternator volts. Regulation in parallel is also greatly facilitated, as it is only necessary to move one small rheostat—viz., that in the exciter field circuit—to affect equally all the machines running. It has been urged against this system that it is equivalent to

*From the "Electrical Engineer," London.

putting all one's eggs into one basket, and that the entire safety of the station depends upon one exciter that may easily go wrong. This is quite true—such events have happened more than once, but the risk is one of those we have to take owing to the advantages that go hand in hand with it. As a matter of fact, this difficulty is easily overcome by the installation of an exciter battery working in parallel with the steam sets; indeed, such an arrangement is absolutely the safest that can be devised. It appears upon the face of it that much cannot be said for its economy owing to the loss in the battery, but this is, at any rate to a great extent, made up for by the fact that the exciters are only run for a short period, at full load and maximum efficiency, as opposed to a 24-hour run most of the time at practically no load, and, therefore, at great loss.

It is also a consideration that the exciters can be shut down at the heavy load, when steam is sometimes scarce, and the charging done either during the day or night watches.

A point to be noted when working with accumulators as exciters, and one that constitutes practically the only inconvenience, is that the usual two-volt step is rather too rough for nice regulation; it consequently has to be taken up to a certain extent on the alternator field resistances. As pointed out before in the hands of a careless or incompetent switchboard attendant, this may lead to the setting up of wastful local currents; and to obviate this, it has in cases been found necessary to provide an additional and separate resistance for each machine, capable when all in of absorbing two volts, and mechanically coupled in suchwise that one turn of a large handle will either cut it in or out in all the alternator fields at once. This should not be confounded with the other coupling arrangement mentioned, which applied to the mechanical connection of the ordinary field-regulating resistances.

The third system of excitation, as stated, is capable of sub-division under two heads —the arrangement that renders the alternator automatically compensating for variations in load but takes no account of alterations in power factor, and the more modern method that does both. The former, originally devised by Prof. Elihu Thomson, is shown diagrammatically in Fig. 1. A is a single-phase, eight-pole alternator, and six of the poles are excited in the ordinary way by a small direct current machine, E. The shaft, S, is fitted with the two slip rings necessary for conveying the exciting current to the revolving magnets, and a commutator of as many segments as there are poles in the field.

In the main circuit of the alternator,

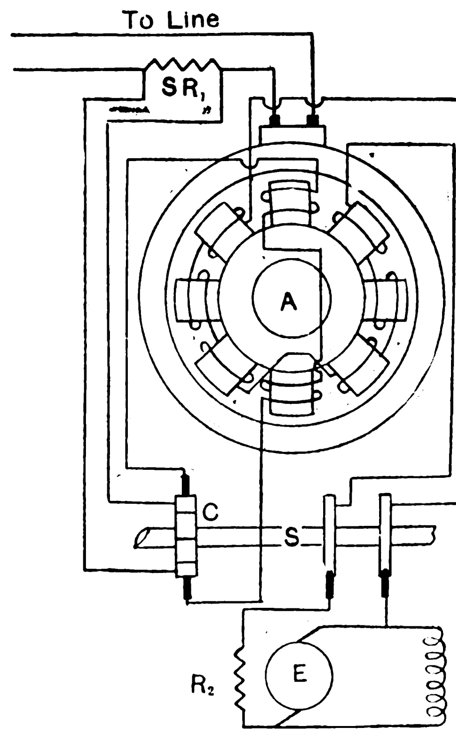

FIG. 1.

shown at the top of the figure, is a low resistance, $S R_1$, from the two ends of which wires are taken to the commutator segments, placing the commutator as a whole in shunt to the resistance; the brushes in contact with the commutator are connected to the windings of any two diagrammatically opposite poles, as shown. By this arrangement the alternator is compounded—that is to say, its

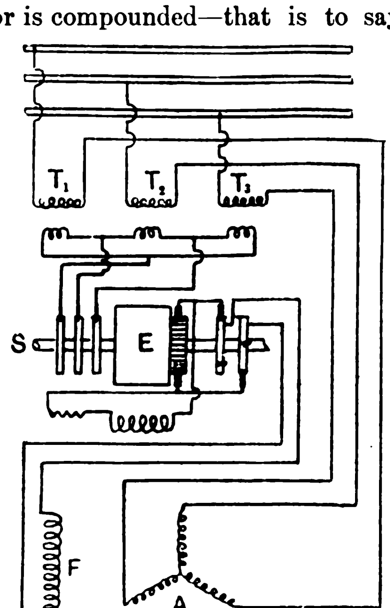

FIG. 2.

voltage will remain more or less constant with a rising or falling load. The action is as follows: The greater the current generated by the machine, the greater the drop in volts over R_1, therefore the larger the proportion of current that flows to the rectifying commutator, and thence round the windings of the two poles, adapted for that purpose. This, of course, results in a proportionate increase of field and the generation of a higher EMF. in the armature windings. Any regulation necessary beyond this is performed in the usual way, either by resistance, R_2, in series with the exciter, or by another in its shunt circuit.

As long as the EMF. and current are in phase, and the power factor, therefore, unity, this method serves very well, but these conditions are very infrequently met with owing to lagging currents produced by the asynchronous motors and lightly-loaded transformers that are found in most circuits. As is well known, lagging currents tend to demagnetize the alternator field; therefore the greater the lag the larger the amount of exciting current necessary to compensate for it, and this in addition to the drop in armature volts due to increased load.

A very good method has been devised to get round this trouble, and machines are now built by several large makers that will automatically compensate over all ranges of inductive or non-inductive loads without any hand regulation whatever. The manner of doing this on a three-phase circuit is shown in Fig. 2. A is a diagram of the armature on a three-phase alternator, upon the shaft of which, S, is mounted the exciter armature and commutator, E. This exciter has the same number of field poles as the alternator, so the electrical effects produced in the armature are in strict synchronism with those in the alternator armature. It excites itself, as shown, in shunt direct from the brushes through a regulating resistance. The main current produced passes to the two slip-rings on the right, and so to the revolving alternator field, F.

So far, this is but one of the ordinary methods, and the novelty of the apparatus, and its compensating action, depend upon the three small transformers, T_1, T_2, T_3, and their connection through slip-rings to the exciter armature.

As will be seen, the primaries of the transformers are respectively connected in series with the three main leads from the alternator armature to the 'bus bars; the secondaries are connected as shown, and joined up to the exciter armature at electrically equidistant points by the intervention of the three slip-rings and brushes. Upon the face of it this arrangement may appear rather complicated but its action is really very simple.

The connections to the exciter armature are so made as to cause the auxiliary current supplied from the transformers to set

up magnetic poles in the armature of opposite sign to those of the fields, and, therefore, to strengthen them.

It will be easily seen that on a non-inductive load when the current is in phase with the EMF. an increase of output will naturally result in an increase of alternating current fed into the exciter armature, and, therefore, a strengthening of its field, raising of its volts, and an increase of the current it supplies to the alternator field. On a non-inductive load the magnetic effect of the superimposed current in the armature leads by about a quarter of a period the effect due to the exciter field, but at the same time helps it sufficiently to give the above results on the alternator volts. Now, presuming the load suddenly becomes inductive, the result in the alternator armature is a lag of the current behind the EMF., and consequent demagnetization of the field and reduced volts. The superimposed current in the exciter armature now lags behind its former value, and its magnetizing effect thus approaches nearer to that of the exciter field, consequently helping it more and more as it gets nearer and nearer into phase with it, and thereby increasing the exciter volts, and likewise those of the alternator. On a load containing capacity the manner of action is identically similar, but converse in its results. The armature current will now lead the volts, and the portion that is fed into the exciter armature, as its effect is now leading the field excitation by considerably more than a quarter of a period, will start to oppose it, so lowering the exciter volts, and consequently those of the alternator, which have risen owing to the magnetizing effect of the leading current in the armature on the fields. This method has in all cases that have justified its use given great satisfaction, and there appears to be a large field for it in connection with circuits of which a varying power factor is a feature.

Beyond the above systems of excitation, there is yet another that was in some small use several years ago. It aimed at making an alternator as independent of separate excitation as is a direct-current machine, and this result was attained by winding a series of extra coils on the armature core, bringing the ends to a commutator fixed upon the shaft. This practice has long been discontinued, as its bad points were found to more than equal any benefits that were derived from the absence of separate exciting plant.

With regard to the Elihu Thomson system of compounding, it should be noted that unless a transformer is used instead of the series resistance, the latter should always be placed in the earthed side of the circuit, as otherwise there would be the necessity of extra good insulation on the compounding poles and commutator, and the risk from shock would be serious. Not very many years ago it was customary not to earth one side of the system, under which conditions this machine must have given trouble with the insulation, or at any rate made any dealings with the commutator very dangerous when running.

A few words about the exciting-current switchboard arrangements may not be amiss. Going back again to ancient history, we find many points that were sadly neglected. For instance, the fashion of inserting an ammeter in each alternator field circuit is quite of recent date and a very wise proceeding, as it is of the greatest assistance in working the machines in parallel without the risk of setting up wasteful currents between them. Also resistances have been greatly improved; instead of the old arrangement of a few coarse notches, sometimes hidden, with no attachment to indicate on what portion of the resistance the switch stood, we have rheostats that, while giving a wide range, allow of the most delicate regulation, and if concealed show unmistakably, by means of a mechanically-geared index, the exact proportion of the resistance that is in circuit. There can be no question that the installation of such plant, even though it be comparatively expensive, is justified by the greater ease of working and freedom from break-down risks that go hand in hand with its use.

An earth on the exciter circuit, owing to its usual low voltage, is not a matter of frequent occurrence. It should, however, be guarded against by the use of some simple lamp indicating device, especially in a large station where the cable runs are long and sometimes taken through bad places. Supposing the pressure to be 50 volts, all that is necessary are two lamps of that voltage placed in series across the wires, and a connection taken from between them to earth. Under ordinary conditions the lamps will glow dull red, but if either side goes to earth, one will light up full, and the other go out, the lamp that is out indicating which side of the system the earth is on. If the earth is not dead, there may only be a small difference between the light given out by both lamps, that is to say, they may both be practically only red hot. This, however, can be provided for by the very simple addition of a two-way switch, the arm connected to earth through a low-reading ammeter, and the contacts joined up to the + and — leads respectively. Should the lamps indicate a slight earth, the ammeter, when the switch arm is on the opposite side of that upon which the fault has taken place, will give a reading, from which, by Ohm's law, can be roughly determined the resistance of the fault. It is advisable that a fuse should be in circuit to prevent danger in the event of the switch being used when one of the lamps shows practically a dead earth.

Field switches, it is hardly necessary to state, should be of such a design as to preclude any danger of breaking down the insulation of the magnet winding when cutting the current off it. The rise of potential when the circuit is suddenly broken is enormous, especially in alternators with heavy magnets, and it is necessary that the switch should be so arranged as to insert some form of resistance in circuit before opening, and then to short-circuit the field winding in such a manner as to allow the current in it to die down gently.

In conclusion, the writer would beg to put forward a plea for the better usage of the exciter circuit as a whole; too frequently it is thought nothing of, and provided with a minimum quantity of inefficient apparatus that sooner or later goes wrong often with disastrous effect. The correct way has been pointed out by Ferranti and others in their manufactures, and the thanks of the electrical world are due to these firms, who have made the path of the exciting current as smooth as could be desired.

ELECTRICAL STATION PRACTICE.

ARTICLE XXV.

BY W. H. RADCLIFFE.

In former years there was considerable difficulty experienced in providing suitable insulation within a transformer between the primary and secondary windings. Consequently, the transformation of a high pressure necessitated the use of several transformers in series so that across each of them there would be a comparatively low voltage. The series connection, however, is no longer rendered necessary on account of the adoption of modern methods in design and construction whereby transformations from the highest pressures in commercial use can safely be accomplished in a single tranformer.

In many installations, however, it is frequently found advisable to operate transformers in multiple, so that each of

them may carry approximately that load for which it was designed to give maximum efficiency. In order that transform-

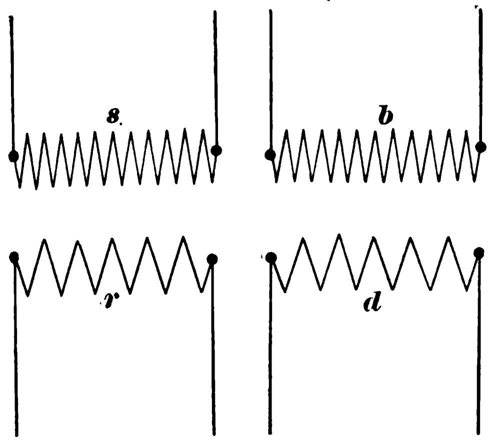

FIG. 21.

ers may give satisfactory results when thus connected, they must be designed for the same pressures and capacities, they must have the same polarity at a given instant, and their percentages of regulation should be the same. One may satisfy himself as to the first of these conditions by examining the name plates fastened to the transformers, whereon are stamped the values of the respective pressures and capacities of each. For information regarding the third condition a special test must be applied.

The test for polarity consists in joining,

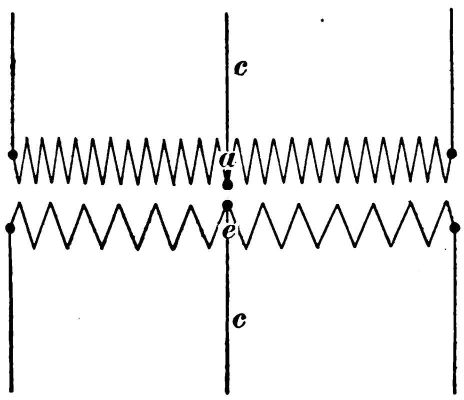

FIG. 22.

by means of a fuse wire, a terminal of the secondary winding of each transformer, and then with the primary windings supplied with normal voltage, connecting temporarily the remaining terminals of the secondary windings. The melting of the fuse wire thus connected indicates that the secondary terminals joined together are of opposite polarities, and that the connections must therefore be reversed, whereas if the fuse wire does not melt it shows that the proper terminals have been joined and that the connections may be made permanent. The object of this test is, obviously, not to determine the exact polarity of each secondary terminal, but merely to indicate which of them are of the same polarity.

Although equal values of regulation is given as one of the conditions to be satisfied, transformers may be operated in parallel when their percentages of regulation are not the same. Ideal operation, however, can only be attained under the former state of affairs. Suppose, for instance, a transformer having a regulation of 2 per cent. be operated in parallel with another of similar size and design but having a regulation of 1 per cent. The secondary pressures of these transformers

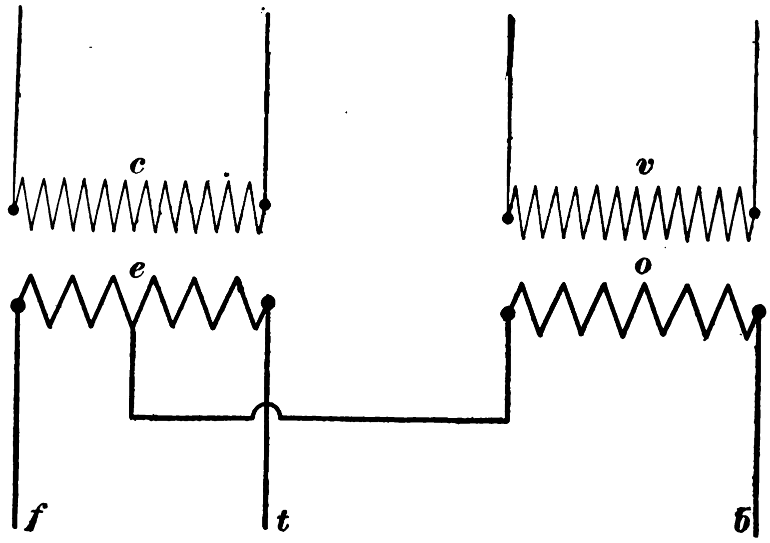

FIG 24.

at no load will of course be the same, but at full load if the secondary electromotive force of the one is 98 volts that of the other will be 99 volts. There will, therefore, be a difference of potential of 1 volt between them which will tend to force a current backward through the secondary winding of the transformer delivering 98 volts. This reversed current,

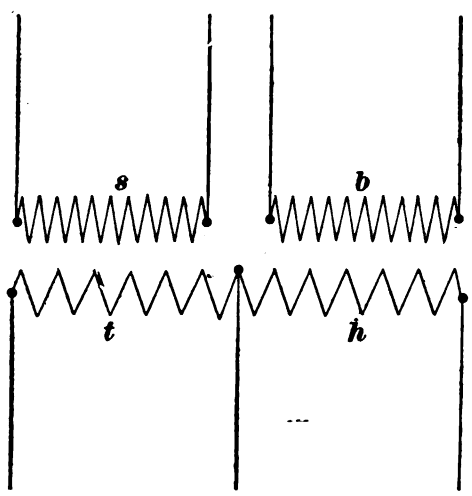

FIG. 23.

although comparatively small in value, lowers the efficiency of the installation by causing a displacement of phase and a decrease in the combined power factor of the transformers.

As previously stated the usual type of transformer has one primary winding and two secondary windings, the latter of which may be joined either in series or in multiple with each other. With the secondary windings in multiple connection, the ratio of primary voltage to secondary voltage in a step-up transformer would be one-half that obtained with the secondaries of the same transformer in series connection but the value of the current would be twice as great. In a step-down transformer the ratio with the secondary windings connected in multiple would be twice that with a series connection, but the value of the current would be but one-half as great.

On a two-phase four-wire alternating current system, transformers are generally connected, as shown in Fig. 21 where *s r* represents a transformer connected in the one phase, and *b d* a second transformer connected in the other phase. In this diagram *s* and *b* represent the respective primary windings on the two transformers, and *r* and *d* the respective secondary windings. This connection is almost entirely employed for lighting and for long two-phase circuits of any kind.

When two-phase installations are operated on the three wire system, two transformers are necessary but these are joined together as shown in Fig. 22, the adjacent ends of both primary and secondary windings being connected together at *a* and *e* respectively, and a common wire, *c*, in both cases led to their respective junctions. Whatever be the primary or the secondary voltage between the common wire, *c*, and either one of the outside wires, this voltage multiplied by 1.414 will equal the pressure in volts between the respective outside wires from either primary or secondary winding.

The transformer connections illustrated in Fig. 23 are used whenever it is desired to convert a two-phase four-wire alternating current system into a two-phase three-wire system, or vice versa. A close

inspection will reveal the fact that the primary arrangement *s b* of the two transformers employed is the same as that shown in Fig. 21, while the secondary arrangement *t h* of the two transformers is the same as that shown in Fig. 22.

A somewhat similar connection to that shown in Fig. 23 is employed when it is desired to convert a two-phase system into a three-phase system, or vice versa. This case is represented diagrammatically in Fig. 24. Two transformers are used, the primary windings *c* and *v* of which are connected to the four wires of the two-phase system as there shown. Suppose there be 1,000 volts across each circuit of the two-wire system, and that it be desired to transform this to a 100-volt three-phase system. The connections must therefore be such that there be 100 volts between *f* and *t*, 100 volts between *t* and *b*, and 100 volts between *f* and *b*. To effect the desired result it is necessary to have the secondary winding *e* in one of the transformers so designed that each half of it will give 150 volts when there is 1,000 volts across its primary winding *c*. Then, if the entire secondary winding *o* of the other transformer be designed to give 86.6 volts with 1,000 volts primary, and it be connected between the two halves of the winding *e* as indicated, there will be supplied to the wires *f t b* a 100-volt three-phase alternating current. This connection of transformers is valuable in that the commendable points of both the two-phase and the three-phase system may be taken advantage of in one system without their respective disadvantages being introduced.

On three-phase alternating-current circuits, transformers may be wired in two ways, the selection of the one method over the other being usually governed by the value of the pressure in use. When high pressures are employed, what is known as the star connection is generally chosen. A diagram showing three transformers thus connected on a three-phase circuit is given in Fig. 25. The primary coils of the three transformers are shown at *v*, *m* and *z*, and their respective secondary coils at *c*, *r* and *e*. Since there are two transformers between any of the line wires *d*, *f* and *b*, the line voltage is not subjected to any one primary winding. Whatever be the pressure between any two of the line wires, the pressure across any one of the primary coils *v*, *m*, or *z*, will be but .577 of that amount, while the pressures induced in the secondary coils will be governed of course by the ratios of the respective transformers. Whatever the value of the secondary pressure induced in each transformer this value will, if multiplied by 1.732, equal the pressure between any two of the secondary distributing mains. The value of the star method for connecting transformers together is now evident, for it is seen that but little more than half the line wire voltage is subjected to each of the primary windings. The star method also possesses advantages over the mesh connection, when, for secondary distribution, a connection is made to the common junction of the secondary windings of the transformers.

As to the primary and secondary currents in this form of connection, that in each primary winding of the transformers is the same as that in the respective line wires between which it is connected. The value of the induced current in each secondary winding of the transformers is greater than that in the corresponding primary winding, in the same proportion as the respective secondary pressure is less than the corresponding pressure in the primary winding. In the secondary distributing mains the current is, of course, the same as in the secondary transformer windings connected thereto.

The mesh connection is more generally employed for three-phase work than is the star connection, unless for reason of the high pressures in use or on account of certain special forms of secondary distribution the star connection is particularly advantageous. In Fig. 26 is given the method of wiring three transformers in mesh connection on a three-phase circuit. To avoid confusion between the mesh and star connections, the similar parts in Fig. 25 and Fig. 26 are lettered the same; by this means there should be no difficulty in understanding the difference between the connections. If now there be a certain voltage between any two of the line wires *d*, *f* and *b*, the voltage across any one of the primary coils *v*, *m* or *z* will be of the same value, while the pressures induced in the secondary coils will, as in the star connection, be governed by the ratios of the respective transformers. Whatever this secondary pressure in each transformer be, this same pressure will exist between any two of the secondary distributing mains.

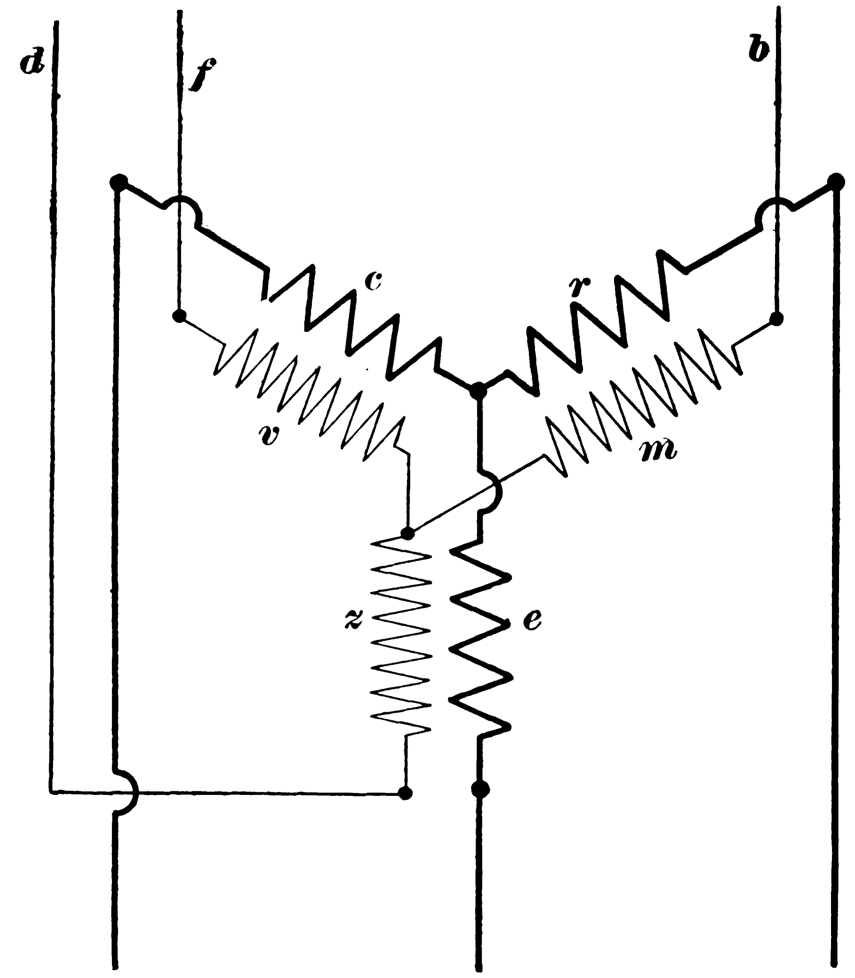

Fig. 25.

Let us now see what happens to the current. Since between any two of the line wires *d*, *f* and *b*, the primary windings of the transformers form a divided circuit, the current in each primary winding will be but .577 of the current in the line wires. The induced current in each secondary winding of the transformers is greater than that in the corresponding primary winding, in the same proportion as the respective secondary pressure is less than the corresponding pressure in the primary winding. In the secondary distributing mains

the current will be 1.732 times that in the secondary transformer winding connected therewith.

The value of the secondary voltage in a three-phase system with respect to the primary voltage may be altered by changing the connections of the transformers to the line wires and distributing wires without changing the respective ratios of the transformers in any way. Thus, if three transformers each with a ratio of 1 to 1, have their primary windings joined in star connection with the three-line wires, and their secondary windings joined in mesh connection with the three distributing wires, the pressures across the secondary circuits will be but .577 of those across the primary circuits. If instead of each transformer having a ratio of 1 to 1, it have a ratio of 10 to 1 with the same connection in use, then the pressure across the secondary circuits will be but one-tenth of .577 or .0577 of those across the primary circuits. The ratio is then 17.3 to 1 instead of 10 to 1, which latter would be the proportion were the transformers joined together with both primaries and secondaries either in star or in mesh connection.

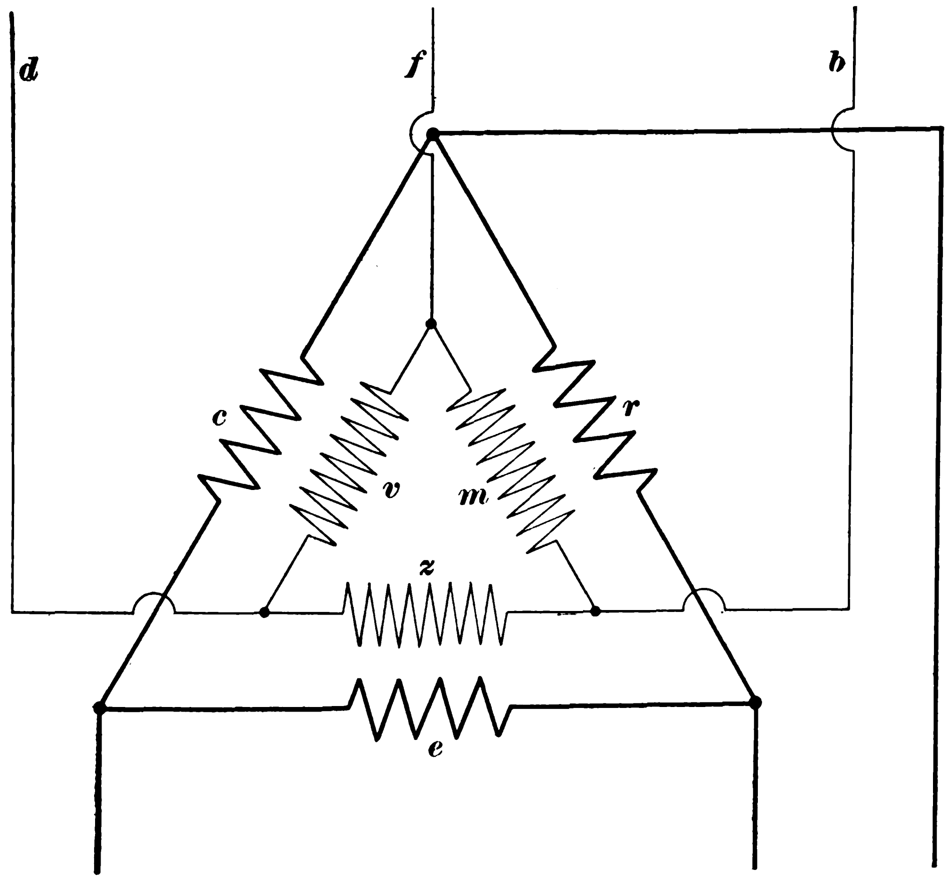

FIG. 26.

Finally, if the transformers each with a ratio of 10 to 1 have their primary windings joined in mesh connection with the three-line wires and their secondary windings joined in star connection with the three distributing wires, the pressures across the secondary circuits will be one-tenth of 1.732 or .1732 of those across the primary circuits. The ratio is then 5.77 to 1 instead of 17.3 to 1, which latter, as has been shown, is the proportion with the mesh and star connections reversed.

COIL WINDINGS FOR ELECTRICAL PURPOSES.*

BY RICHARD VARLEY AND CHARLES R. UNDERHILL.

(*Concluded from page 94.*)

Now let us consider the section and length of insulated wire which is to comprise the winding. First let us get our resistance coefficients.

It has been found by experiment that a commercial soft copper wire .001 inch in diameter has a resistance, at 68 degrees F., of 10.3541 ohms. Now, since for the same length, the resistance of a conductor decreases in direct ratio to the sectional area of the conductor, the resistance will vary with the square of the diameter of the wire. Therefore, denoting the diameter of the wire by $\triangle$, the ohms per foot for any diameter of copper wire will be

$$\frac{.0000103541}{\triangle^2}, \text{ or the ohms per inch}$$

$$\frac{00000086284}{\triangle^2}$$

It is obvious that if we know the length of a given wire that will just fill the bobbin in question we may quickly find the resistance by multiplying the length of the wire by the resistance per unit length. But here we must consider the sectional area of the wire and insulation. For wires of a smaller diameter than No. 20 B. & S. the cotton insulation makes the total diameter .004 inch greater than the diameter of the wire. This is generally referred to as a 4 mil increase.

When the wire is wound into the bobbin, the turns of one layer cross the turns of adjacent layers at an angle, which is dependent upon the diameter of the wire and the diameter of the turn. Therefore, at a certain point on each turn, the corresponding turn of the adjacent layer will be centrally over this turn, but 180 degrees around where the wires cross one another, the wires will imbed slightly.

The gain due to imbedding is approximately 7.3 per cent., but since this gain in space is about equally offset by the spreading of the insulation laterally, due to the vertical tension on the wire during the process of winding. The longitudinal sectional area of the bobbin consumed by each turn of wire is approximately equal to the square of the diameter of the wire and insulation.

The turns, then, are equal to the longitudinal cross-sectional area of the winding divided by the square of the diameter of the wire plus insulation, or $N = \frac{\pi L}{g^2}$

Where

N total number of turns in the winding,
π = thickness of winding,
L = length of winding,
g = diameter of wire plus insulation.

Now the total length of the wire L w in the winding will, of course, be equal to the number of turns multiplied by the average length of all the turns, or

$$L\,w = \frac{\pi\,L\,(D^2 - d^2)}{4\,g^2}$$

Therefore the resistance P of the winding will be

$$P = \frac{.00000086284\,\pi\,L\,(D^2 - d^2)}{4\,g^2\,\triangle^2} = \frac{.0000027107\,L\,(D^2 - d^2)}{4\,g^2\,\triangle^2}$$

To simplify the operation in practice, it is customary to calculate separately the constants for the various sizes of wire, both the resistance and space factors. Since for any given size of insulated wire with given insulation the space and resistance factors may be resolved into the combined space and resistance factor, and in

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

this factor the constant π is incorporated, therefore the resistance P may be found by the simple formula:

$$P = RL\left(\frac{D^2 - d^2}{4}\right)$$

where R equals the combined space and resistance factor.

Space and resistance factors are arranged in the form of tables for reference therefore only the volume of the bobbin need be found in order to ascertain the resistance which may be contained therein with any size of wire, or the size of wire may be determined which will give the desired resistance for any winding volume. In this latter case, however, the true outer diameter of the winding must be recalculated, as the calculated constants seldom coincide with the tabulated constants, therefore the next smaller size of wire is taken and the true outside diameter of the winding calculated by the formula:

$$D = \sqrt{\frac{4P}{RL} + d^2}$$

For windings of square or rectangular cross-section special formulæ are required. However, these formulæ only have to be used in determining the average length of all the turns, as the thickness and length are the same as in a winding or circular cross section.

In order to obtain the theoretical results in practice certain precautions must be taken, for instance, the actual diameter of the insulating sleeve must be taken, and also the exact diameter of the wire and the thickness of the insulation. A change of one ten-thousandth of an inch in the diameter of a No. 35 wire will change its resistance about 6 per cent. for equal lengths of wire, therefore caution must be taken to be sure that it is not stretched during winding, as the ampere turns will be materially reduced.

A slight increase in the insulation will also make a marked change in the amount of wire in a winding.

Also, in calculating the weight of insulated wire the specific gravities of the wire and insulation must be known.

RECTIFIERS.*

BY PROF. CHARLES F. BURGESS.

To correct or redress an alternating nt so that it may serve certain purposes, such as charging storage batteries, is the function of the so-called alternating current rectifier. The perfection of these devices has occupied the attention of various engineers and scientists during recent years, and the progress made has been such as to bring the subject to a state of practical importance to the central station operators.

A rectified current, properly speaking, is that derived from an alternating source of pressure in which both halves of the complete alternating cycle are utilized. The ideal rectified curve would be produced by inverting the lower half of the alternating curve, the resultant being a curve of unidirectional, pulsating nature. The term, however, is sometimes improperly applied to the interrupted pulsating current produced by suppressing one-half of each cycle, but the newest and most improved rectifiers utilize the complete cycle.

Rectifiers may be divided into three general types, mechanical, vapor and electrolytic.

Omitting the rotary converter, which is essentially a direct current dynamo driven by an alternating current motor, and is not a rectifier in the commonly accepted meaning of the term, the mechanical rectifiers include the synchronously-driven, rotating reversing switch, and the vibrating reverser in which the contact maker is maintained in synchronous vibration by energy derived from the alternating circuit. The destructive sparking which it is almost impossible to suppress, and the tendency of the storage battery or other translating device to discharge when its pressure is greater that the instantaneous values of the pulsating rectified pressure, have prevented these devices from being extensively adopted in spite of their low cost as compared with the rotary converter. A vibrating rectifier was advertised not long ago by an English manufacturer, but the inertia of the moving part, together with the objections referred to, undoubtedly will prevent this from being of value except for the smallest capacities.

Certain materials have been discovered which have a low resistance when the current flows in one direction and an extremely high value when the direction of the current flow is reversed. Conductors possessing this property have been designated "asymmetric" conductors. It is this property that the vapor and electrolytic types of rectifiers utilize.

The electric arc playing between carbon terminals has for a long time been known to possess the property of asymmetry, but not in sufficient degree to warrant its practical application. In the discovery of the so-called "Edison effect" some twenty years ago, it was shown that a rectified current could be obtained from an alternating current by means of an extra electrode inserted in an incandescent lamp. Various other vapors have been found to possess this property, the most pronounced results being those recently pointed out by Mr. Cooper Hewitt in his remarkable work on the conductivity of mercury vapor. In this Mr. Cooper Hewitt has demonstrated the possibility of utilizing the mercury vapor conductor in the construction of a rectifier or converter having an efficiency of 98 per cent. and above. His apparatus is remarkable in its large amount of energy converted per unit of weight and volume and also for the high efficiency, which can scarcely be approached by any other form of electrical converting apparatus. At present these converters are apparently in the development and experimental stage, but hold out great promise as a successful rectifier for various classes of service.

Though for the past 20 years it has occupied a prominent place in scientific and technical literature, the third class or the electrolytic rectifier has only recently been placed upon the market in this country. This form of rectifier is sometimes designated as an electrolytic valve, and, as such, has an analogy in the hydraulic check-valve which automatically allows water to flow freely through a pipe in one direction, but prevents its passage in the opposite direction. The discovery upon which the electrolytic rectifier of to-day is based was made a half century ago when it was found that aluminum in certain solutions possesses the property of opposing in a high degree the passage of the current from it to an electrolyte, and of freely allowing its passage in the opposite direction.

It will be evident that the efficiency of such an electric valve must depend upon the rapidity with which it acts, upon the completeness with which it stops the flow of current in the one direction, and upon the high conductivity which it allows for the passage in the reverse direction. With the commercial frequencies now employed of from 25 to over 100 per second it is evident that this valve must act with great rapidity. Without going into details as to this factor, or the method of determining it, I may state that an investigation of this question in our laboratory has shown that an aluminum plate immersed in a sodium nitrate electrolyte required about 1-1100 second for "closing the electrical valve" at each reversal of pressure.

There are many solutions which in contact with aluminum allow this electrolytic valve action to become manifest. Some solutions are naturally more efficient than are others and it is to the study

* Paper read at the twelfth annual convention of the Northwestern Electrical Association held at Milwaukee, Wis., Jan. 20-22, 1904.

of the relative behavior of different materials that most attention has been given during the past few years.

Although extravagant claims have been made from time to time as regards efficiency, durability and other factors, these claims have almost invariably failed of realization under practical conditions, and it is only recently that improvements have brought the working efficiency of the apparatus up to a point where it can be used commercially. It is not yet all that may be desired, but for certain classes of work, such as charging small storage battery equipments, it offers decided advantages.

Among these advantages which have made the electrolytic rectifier an attractive problem for study and investigation are the following: In possessing no moving parts it is a close approximation to the static alternating current transformer, requiring little or no attention during operation. The materials of which it is constructed are cheap and the total cost should be lower than that of the ordinary transformer for equivalent outputs. The electrolytic rectifier has a high power factor. It requires little or no abnormal rush of starting current. It has in its present condition an efficiency in the neighborhood of 50 per cent., and, what makes it especially desirable for a certain class of work is that it can be made in small sizes at such a cost as will permit its general use where small storage batteries are to be charged from alternating current circuits. Where direct current circuits are available and two or three more storage cells are to be charged from them, the common, though wasteful method, is to connect the batteries in series with a suitable resistance, with the electrolytic rectifier, advantage may be made of pressure transformation rather than rheostatic control, thus effecting a large saving in the power consumption.

The electrolytic rectifier has certain limitations, one of which is that for a single cell a pressure much greater than 50 or 60 volts cannot be maintained at a high efficiency; and where higher pressures are necessary two or more cells must be operated in series.

Tests which have been made in our laboratories on the efficiency of a large number of electrolytic rectifiers of various types have shown that the best of them operate, under practical working conditions, at an efficiency between 50 and 60 per cent. Tests on various sizes of a certain type of rectifier have shown that this efficiency is practically constant, regardless of size, and in this respect the rectifier differs materially from most types of electrical apparatus, where the efficiency usually increases in value as the size of the outfit is increased.

(*To be continued.*)

American Institute of Electrical Engineers.

The 184th meeting of the American Institute of Electrical Engineers will be held at the Chemists' Club, 108 West 55th street, New York, Friday, February 26, at 8:15 P.M. The following papers will be presented and discussed: "European Practice in the Construction and Operation of High-Tension Transmission Lines and Insulators," by Guido Semenza, chief electrical engineer of the Italian Edison Company of Milan, Italy; "Conductivity of the Atmosphere at High Voltages," by Harris J. Ryan, professor of electrical engineering, Sibley College, Cornell University, Ithaca, N. Y.

Society of Chemical Industry.

The New York Section of the Chemists' Club met last Friday evening at 108 West 55th street. The following papers were read: "A Method of Determining the Percentages of Aldehydes in Certain Essential Oils," by Samuel S. Sadtler; "Graphitic Acid or Oxide," by Frederic S. Hyde; "Radium and Radio-active Substances" (demonstration and exhibits), by Hugo Lieber; "The Iodine Absorption of Spirits of Turpentine," by R. A. Worstall.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 16, 1904.

Electric Railways and Appliances.

752,037. Electric Train-Service. Melvin D. Compton, New York City. Filed Dec. 2, 1901. Renewed Sept. 12, 1903.

752,121. Trolley-Finder. Elisha S. Stitt, Newton, Mass. Filed Oct. 17, 1902.

752,127. Railway Switching and Signaling Apparatus. John D. Taylor, Buffalo, N. Y., assignor to the Taylor Signal Company, same place. Filed Jan. 12, 1901.

752,139. Trolley-Catcher. William C. Young and Johnston McMahon, Buffalo, N. Y. Filed June 1, 1903.

752,374. Automatic Check Device for Trolley-Cords. Seth J. Buckland, Springfield, Mass. Filed April 22, 1903.

752,437. Overhead-Trolley Guide. Charles W. Burkhead, Madisonville, O. Filed Aug. 16, 1902. Renewed Oct. 22, 1903.

752,501. Trolley-Hanger. Montraville M. Wood, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 8, 1903.

Electrical Machinery and Apparatus.

752,048. Electric Meter. Thomas Duncan, Lafayette, Ind. Filed Oct. 23, 1903.

752,097. Automatic Starter for Electric Motors. William C. O'Brien, Baltimore, Md. Filed May 4, 1903.

752,168. Dynamo-Electric Machine. Hans Holzwarth, Hamilton, O., assignor to the Hooven, Owens, Rentschler Company, same place. Filed Nov. 21, 1903.

752,192. Electric Switch. Charles C Badeau, Swissvale, Pa. Filed Aug. 12, 1903.

752,236. Electric Generator. Hans Liebreich, Boston, Mass., assignor to the International Electric Company. Filed June 29, 1903.

752,345. Electromagnet. James C. Keller and Otto F. Kadow, Cleveland, O. Filed May 23, 1903.

752,376. Electric-Brush Holder. De Witt C. Cookingham, Cleveland, O., assignor of one-half to John H. Hertner, same place. Filed Oct. 15, 1903.

752,384. Electrical Igniter for Explosive-Engines. Willard E. Dow, Braintree, Mass. Filed July 2, 1903.

752,391. Electric Motor. Christian Fleischmann, Bloomfield, N. J. Filed June 24, 1903.

752,405. Transformer. Charles B. McCurdy, Warren, O., assignor, by direct and mesne assignments, to the Peerless Electric Company, same place, and Frederick C. Sutter and Robert V. Bingay, Pittsburg, Pa. Filed April 24, 1903.

752,528. Protective Means for Electric Boosters. Maxwell W. Day, Schenectady, N. Y., assignor to the General Electric Company. Filed July 6, 1903.

752,531. Electric Switch. Warren K. Dodge, Manhattan, Kan. Filed Oct. 23, 1903.

Telephones and Telephone Apparatus.

752,184. Hanger for Telephone Transmitters. Micheal Setter, Chicago, Ill., assignor to the American Electric Telephone Company. Filed May 8, 1902.

752,251. Automatic Telephone System. John K. Norstrom and John J. Brownrigg, Chicago, Ill., assignors, by direct and mesne assignments, to the Globe Automatic Telephone Company. Filed June 28, 1901.

752,613. Relay. Albert Carliss, Chicago, Ill., assignor to the American Electric Telephone Company. Filed May 25, 1901. Renewed Dec. 23, 1903.

Miscellaneous.

(Issued Feb. 9, 1904.)

751,739. Insulator. Peter S. Lindell, Edinburg, Pa. Filed March 31, 1903.

751,743. Insulator. Joseph M. Mahoney, Boston, Mass. Filed Dec. 1, 1902.

751,760. Electric Signaling Apparatus. John E. Stannard, Springfield, Mass. Filed Feb. 2, 1903.

751,664. Electric Insulator. Thomas T. Lyman, Montclair, N. J., assignor to the H. W. Johns-Manville Company, New York City. Filed April 4, 1902.

751,772. Storage Battery Plate. Charles B. Askew, Chicago, Ill. Filed May 20, 1903.

751,780. Electric Signal. Harold E. Bradley, Warwick, R. I. Filed Oct. 3, 1903.

751,781. Electric Alarm Clock. Harry A. Chase, East Orange, N. J. Filed March 6, 1900.

751,788. Electrical Signal Apparatus. John M. Golding, Washington, D. C. Filed July 15, 1903.

751,803. Wireless Electric Apparatus Acting on Type-Writers. Giuseppe Musso, S. Angelo del Lombardi, Italy. Filed Sept. 23, 1902.

751,818. Electrically Produced Sound Intensifier. Gustaf T. Swenson, San Pedro, Cal. Filed Dec. 17, 1902.

751,831. Insulator Pin. James H. Bullard, Springfield, Mass. Filed Aug. 8, 1903.

751,839. Electric Hair Brush. Henry C. Doersch, Nyack, N. Y., assignor of one-half to William S. Pickard, Brooklyn, N. Y. Filed June 1, 1903.

751,857. System of Electrical Propulsion. Erich Krause, Hoboken, N. J., assignor of one-fifth to Hans Kurten and Rosa Kurten, same place. Filed Oct. 22, 1903.

(Issued Feb. 16, 1904.)

752,150. Electric Selective System. Julien A. Gehrung, St. Louis, Mo. Filed Feb. 8, 1902.

752,259. Telegraph-Pole. John H. Purdy, New London, O. Filed June 15, 1903.

752,349. Battery Stem-Guide. William H. Martin Nevada City, and Alexander McComble, Grass Valley, Cal. Filed July 22, 1903.

752,357. Process of Electrically Heating Articles. Edgar F. Price, Niagara Falls, N. Y., assignor to the Union Carbide Company. Filed Nov. 5, 1902.

752,358. Process of Heating Articles by Electricity. Edgar F. Price, Niagar Falls, N. Y., assignor to the Union Carbide Company. Filed Nov. 5, 1902.

752,408. Electrical Apparatus for Producing Sound-Signals. Charles H. O'Brien, Augusta, Me. Filed Nov. 1, 1902.

752,419. High-Tension Therapeutic Electrode. Manuel R. Rodrigues, Brooklyn, N. Y. Filed June 3, 1901. Renewed July 9, 1903.

752,493. Molding-Case for Use in Electrotyping and Process of Manufacturing Same. William H. Welsh, Collingswood, N. J. Filed Oct. 13, 1903.

752,533. Wireless Signaling. Daniel Drawbaugh, Eberlys Mills, Pa. Filed March 1, 1902. Renewed July 15, 1903.

752,534. Method of Transmitting Intelligence Through the Natural Mediums. Daniel Drawbaugh, Eberlys Mills, Pa. Original application filed March 1, 1902. Renewed July 25, 1903. Divided and this application filed June 28, 1902. Renewed July 15, 1903.

752,544. Electrical Device for Shocking Horses. James A. Giles, Elberton, Ga. Filed Sept. 24, 1902.

752,589. Electromagnetic Reversing Device. John Riddell, Schenectady, N. Y., assignor to the General Electric Company. Filed May 28, 1900.

752,590. Magnetic Clutch Application. John Riddell, Schenectady, N. Y., assignor to the General Electric Company. Filed July 27, 1901.

THE TELEPHONE WORLD.

Americans to Install Telephone System in Mexico.

An extensive up-to-date telephone system is to be installed in Mexico City. S. G. McMeen, a Chicago expert, is now in that part of the world for the purpose of making a study of the field and mapping the results as a final preliminary to digging trenches and laying the conduit cables. The cables in the underground section of the city will be laid in terra cotta pipes, 18 inches in length. These pipes will be laid in trenches at a depth of about 3 feet from the street. The cables will weigh about 6 pounds per running foot. Percival F. Burgess is the general manager of the company which is to build and operate the new system. A large new central station will be built and a modern switchboard installed. The visual signal system will be employed. All the necessary equipment will be purchased in the United States.

John Woessner, an American, has secured a concession from the Mexican Government to construct an extended long-distance telephone system in Northern Mexico. A system will be installed in Monterey in the first instance. The line will then be extended to Tampico, passing through the towns of Linares, Victoria and other places. The system is also to be extended to the city of San Luis Potosi and thence to Mexico City. Local exchanges will be installed in nearly all of these cities.

By March 15 Little Rock, Ark., will have direct telephone connection with St. Louis, Mo., as that date will mark the completion of a telephone line along the right of way of the main line of the Iron Mountain from St. Louis as far south as Little Rock. The line is being built by the American Telegraph & Telephone Company. The completion of this Little Rock-St. Louis line will also give Memphis a new line to St. Louis via Little Rock. This telephone company put in its own poles as far south as Walnut Ridge. From there south to Little Rock its wires are being strung on the poles of the Southwestern Telegraph & Telephone Company, which has long distance lines in all directions out of Little Rock. The present toll rate to St. Louis from Little Rock via Memphis is $2 for a 3-minute talk from 6 A.M. to 6 P.M., and half that rate for talks at night, or between 6 o'clock in the evening and the same hour in the morning. It is not known whether this rate will be cut.

The entire plant of the Lebanon, Telephone Company of Lebanon, Ind., is being rebuilt. This includes the installation of six sections of new flashlight switchboard and the stringing of 15,000 feet of aerial cable. The work is being pushed very rapidly under the supervision of Floyd Jones, general manager for the company, who says that it will be completed by March 1.

At a meeting of the executive council of the Michigan Independent Telephone Association at Grand Rapids, February 4, it was decided to admit manufacturers and dealers of telephone equipments as associate members of the association on the payment of $5 dues per year.

The Moffit Telephone Company wants a new franchise for the city of Billings, Mont.

New Company Opens Exchange.

For a long time the residents of the lower portion of Luzerne County, Pa., and connecting territory, have been caused much inconvenience on account of not being able to enjoy service, but the opening of the Shickshinny Exchange of the Lower Luzerne Telephone Company lately met with the hearty approval of Shickshinny business men who now, that they have been furnished with efficient telephone service at reasonable rates, appreciate the fact that they would still be handicapped by inadequate service and high tariff had not the new company started operations in their territory. The Lower Luzerne Company has spared no expense in the matter of construction, and the material used and apparatus installed is the very best obtainable, thus insuring good service, and it is the intention of the company to maintain the highest possible degree of efficiency.

A large number of subscribers have been connected with the exchange and new connections are being made daily. The company has also constructed a toll line connecting the Shickshinny Exchange with the lines of the Consolidated Telephone Companies of Pennsylvania at Nanticoke, and with the lines of the United Telephone & Telegraph Company at Berwick, and is therefore prepared to furnish long distance service. The rates for such service are very low as this new line makes a short route and the public will be greatly benefited thereby.

The Independent telephone companies have made remarkable progress in that territory and the opening of this new toll line and the Shickshinny Exchange is but one of the many developments that will soon be brought about. The line has been built with local capital, and the officers are W. G. Harding, president, and Charles West, secretary and treasurer.

At the annual convention of the Independent telephone companies of Wisconsin, recently held in Milwaukee, the old officers were elected as follows; President, Richard Valentine, of Janesville; vice-president, H. G. Slater, of Waupaca; secretary and treasurer, H. C. Winter, of Madison. Nine new companies were received into membership, as follows: The Mazomanie Telephone Company, the Kingston Telephone Company, the Columbia County Telephone Company, the Independent Consolidated Telephone Company of Weyauwega, the Cambridge Telephone Company, the F. Bissell Telephone Company of Toledo, O., the Fulmer Telephone Company of Florence, and the Signalphone Telephone Company of Milwaukee.

The Evansville, Wis., Telephone Exchange Company, by its president, A. S. Baker, and secretary, R. M. Richmond, recently filed an amendment increasing its capital from $2,500 to $20,000.

The Footville, Wis., Telephone Company, by S. W. Lacy, president, and W. O. Howell, secretary, has filed an amendment increasing its capital stock from $4,000 to $10,000.

The net output of the American Telephone & Telegraph Company decreased 32,761 instruments during the month ended January 20 last.

The Cumberland Telephone & Telegraph Company has leased the Globe Telephone Exchange at Cadiz, Ky., from A. P. White. It will overhaul the entire system and in a short while Cadiz will have one of the best telephone systems of any little town in the State. The lease is for an indefinite time. Mr. Will Collins of Hopkinsville, will have charge of the business in Cadiz.

George Carker, William Hawley and William Burgdorf have formed a company for the purpose of constructing a telephone line from Westbury to Wolcott, with a loop to Red Creek, N. Y. They have secured permission to erect the line along the plank road and into the village of Wolcott.

By a recent unanimous vote the Butler County, O., commissioners granted the Hamilton Home Telephone Company a franchise to erect and maintain poles and wires for telephone and telegraph purposes along the roads and highways of that county under the usual conditions.

The Ellsworth Mutual Telephone Association of Ellsworth, Ia., has been formed with a capital of $10,000 by John H. Sparhoe, Holden Thompson, O. M. Lyders, Barney Peterson, John O. Anderson, Dan Knudson, F. R. Dalbey, John P. Holt and M. H. Brinton.

The Dayton, O., Home Telephone Company, by the necessary procedure recently brought in the office of the Secretary of State, reduced its capital stock from $750,000, to $600,000, and immediately increased its capital to $1,000,000, the increase being 5 per cent. preferred stock.

The reconstruction of the telephone system in Manila is projected. The Philippines Commission is now considering a proposed act which will direct the Manila Telephone Company to install a new switchboard and other modern appliances in the central office and in other portions of the system.

The People's Rural Telephone Company, with registered office at Wenonah, N. J., has a capital stock of $50,000. Warren Atkinson, George Horner, Asa Moore and others are the incorporators.

R. S. Underwood, traffic agent of the Cumberland Telephone Company, will resign his position March 1 to accept the position of superintendent of the Central Union Telephone Company at South Bend, Ind.

The Barron County, Wis., Telephone Company, by De Witt Post, president, and T. W. Borum, secretary, lately filed an amendment increasing the capital stock from $2,500 to $20,000.

The Wright County Telephone Company of Waverly, Minn., has been incorporated with a capital of $50,000.

Telephone Incorporations.

The Egg Harbor Telephone Company, Egg Harbor City, N. J. Capital stock, $10,000.

The City Telephone Company, Turtle Lake, Wis. Capital stock, $2,000. Incorporators: Frank E. Fisk, John Hogan and W. W. Fisk

GENERAL ELECTRICAL NEWS.

LIGHTING.

Bay City, Mich.—The citizens will vote April 4 on the issue of $50,000 of bonds to put the municipal electric light and power plant in condition to furnish electricity to private consumers.

Browning, Mo.—This village proposes to have electric lights.

Brownsville, Ore.—This town is soon to have electric lights.

Burlington, Wis.—The council has appointed a committee of citizens to investigate the feasibility of building a municipal electric light plant.

Caldwell, Ida.—This city is figuring on putting in an electric light plant. Mayor Stennenberg will report on cost at the next council meeting.

Calhoun, Ga.—T. W. Harbin of this city will require a complete equipment, save boiler, for an electric light plant of a capacity of 12 arc lights and 500 incandescents.

Culiacan, Mex.—The limit of time for the reception of bids for the electric lighting of this city has been extended to March 31.

Danbury, Ia.—The citizens are contemplating the installation of an electric light plant.

Delphi, N. Y.—The citizens are discussing the question of bonding the village for $20,000 for a municipal electric lighting plant,

Des Moines, Ia.—Major R. B. Turner, quartermaster, states that a $40,000 electric lighting plant is to be built at Fort Des Moines. Plans are are now being prepared for same at Washington.

Glasgow, Mont.—The citizens will soon vote on the proposition to establish city waterworks and an electric light plant.

Glenwood, Tex.—A company is reported as projected here for securing electric lights for this place and Polytechnic Hill.

Hartford, Conn.—The Jacob Manufacturing Company, of which L. W. Ripley is treasurer, contemplates the general development of water power, also a hydro-electric light plant and two dams at Glastonbury.

Homer, La.—A movement is in progress to secure electric lighting for this place.

Jeffersonville, Ind.—J. Tompkins, electrician and contractor, will at the next meeting of the Scottsburg town board submit a proposal to erect an electric light plant and furnish the town with illumination.

Kemps Creek, Ala.—Frank F. Taylor, of this place, will want prices on an electric light plant in about 60 days.

Lenox, Ia.—The citizens will vote on granting a 25-year franchise for electric lights at the spring election.

Libby, Mont.—A private electric light plant is to be established if sufficient patronage is guaranteed. A. B. Johnston is interested.

Ligonier, Ind.—The electric light plant here owned by J. W. Draper was lately damaged by fire to the amount of $2,500.

Manistique, Mich.—It is stated that Benjamin Gero has purchased Fred Miller's stock in the Manistique Electric Light Company, paying $10,000 for same. The company contemplates expending $7,000 in increasing the capacity of the plant and otherwise improving it.

Marysville, O.—The city council at its regular meeting introduced a resolution authorizing an investigation to be made of the expense of constructing and operating a municipal electric light plant.

Ness City, Kan.—An electric light company has been organized here and will begin at once installing machinery.

Roberts, Ill.—This city will be lighted with electricity before long.

Sault Ste Marie, Mich.—Alexander Dow and other Detroit capitalists are stated to have bought the Edison Sault Electric Conpany's plant here with the intention of making extensive improvements.

Shippensburg, Pa.—Arrangements are being perfected for the merging of the Shippensburg Gas Company and the Electric Light & Power Company into the Shippensburg Heat, Light & Power Company. The electric power will be furnished by water about two miles distant from the borough.

Springville, Utah.—A special election to bond this city for $14,000 to pay off the indebtedness of the city on the electric light plant resulted in favor.

South Norridgewock, Me.—The citizens are contemplating installing an electric light plant.

South Stillwater, Minn.—The question of voting on the issuance of bonds for an electric lighting plant here will be voted on March 8, and the issue will not be more than $15,000, nor less than $10,000.

Stottville, N. Y.—This town is to have electric lights in the near future.

Stronghurst, Ill.—Messrs. White and Kyler have received an electric light franchise from the village of Kirkwood to cover a period of 20 years, but the exclusive right was omitted.

Sutton, Neb.—The city council has granted a franchise to the Sutton Electric & Power Company to light the city. The franchise runs 15 years.

Walnut, Ia.—It is reported that this city is calling for bids for the erection of an electric light plant. Address A. R. Longnecker, clerk. The estimated cost is about $14,000.

West End, Ala.—The city council and the citizens are contemplating the institution of the municipal ownership, and their first move in this direction will be the erection of an electric light plant.

Willspoint, Tex.—The Willspoint Electric Light Company has been incorporated with $10,000 capital to construct and operate an electric light plant. O. L. Johnson, Charles E. Brown and W. B. Ridges are interested.

STREET RAILWAYS.

Americus, Ga.—A street railway building concern is making negotiations to the end of constructing an electric railway here, and while definite conclusions have not as yet been reached the hope is expressed that Americus will secure this enterprise.

Houston, Tex.—The power plant of the United Railway Company was lately destroyed by fire.

Oshkosh, Wis.—J. K. Tillotson, a promoter of railroads, is here trying to interest the citizens in an electric line for this city.

Philadelphia, Pa.—The West Branch Electric Railway Company has been incorporated with a capital of $18,000.

Pittsburg, Pa.—The Northern Electric Street Railway Company, lately incorporated with a capital of $15,000, has the following directors: F. E. Scott, H. D. Jones and others.

Quincy, Mich.—The common council has granted a franchise to the Toledo & Michigan Railway Company, which proposes to build an electric railway line from Adrian to Coldwater.

Richmond, Va.—It is stated that Frank Gould, owner of the electric street car system here, contemplates its ultimate extension to Washington by the way of Ashland and Fredericksburg.

Saco, Me.—There is a rumor to the effect that a new electric road between here and Bonny Eagle is one of the possibilities of the coming season. James O. Bradbury of this place is interested.

Springview, Neb.—A new company is being formed here to build an electric line from here to Newport, with a capital stock of $300,000. City Engineer Rosewater of Omaha is to be employed.

Stonington, Conn.—A certificate of organization of the Westerly Railway & Lighting Company of this place has been filed in the office of the Secretary of State. The company is organized to construct and operate railroads, street railroads, electric light plants, power plants, gas works and ferries. The authorized capital stock is $400,000.

POWER PLANTS.

Covington, Ga.—There is a company being organized here to develop the water power on Alcovy River, 10 miles south of here. This fall is over 100 feet and a good volume of water that will generate an immense horse power. This water power and a large body of land adjoining belongs to three local capitalists, N. S. Turner, C. H. White and W. C. Clark.

Marble Falls, Tex.—It is reported that the Colorado River Falls at this place are to be utilized for the development of electricity.

Walla Walla, Wash.—The Northwestern Gas & Electric Company is taking steps for constructing a huge power plant on the Walla Walla River near this city in Umatilla County, Oregon. The company will furnish electric power for heating and manufacturing purposes in Walla Walla, Pendleton, Athena and other towns.

BIDS WANTED.

Washington, D. C.—The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until March 1, for furnishing the navy yards at Norfolk, Va., Charleston, S. C., and Port Royal, S. C., with a quantity of electric blowers, electric fans, electric traveling cranes, etc. Blank forms of proposal may be obtained upon application to the navy pay offices in the above-named cities.—William M. Meredith, director of the Bureau of Engraving and Printing in this city, is inviting sealed proposals until April 12 for furnishing the Bureau with a large quantity of electrical supplies, a list of which will be furnished upon application.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12¼@12½c.; Lake 12⅜@12⅝c.; casting, 12¼@12⅜c.

The Michigan Electric Company of Detroit has been placed in the hands of a receiver.

The New Jersey & Pennsylvania Telephone Company is to be sold under foreclosure to satisfy a mortgage for $125,000.

The Chicage Union Traction franchise extension is to be side-tracked until the service has been improved and public confidence regained.

The Memphis Telephone Company has executed a $1,000,000 mortgage to secure the issuance of bonds to pay off indebtedness and to make improvements.

The Newark (N. J.) Electrical & Construction Company has been incorporated under the laws of the State of New Jersey with a capital stock of $125,000.

The Indiana Union Traction Company, the management of which is directed by Philadelphia interests, will hold its first annual meeting, March 1, at Anderson, Ind.

The Chicago Railroad Terminal Elevator Company of New York, which ten years ago issued bonds amounting to $2,500,000, has been placed in charge of a receiver.

Control of the Knoxville (Tenn.) Traction Company and the Knoxville Electric Light & Power Company has been bought from the Railways & Light Company of America by a New York syndicate.

A special meeting of the stockholders of the Nassau Light and Power Company (Brooklyn, N. Y.) has been called for March 4, to act on, among other things, an increase in the capital stock from $500,000 to $1,500,000.

American Telephone & Telegraph Company (Bell) shares have been under attack the past week by Boston and New York "bears." The bond issue of $20,000,000, reported in last week's ELECTRICITY, is not meeting with favor by investors.

Robert E. Wright, C. M. Bates and George W. Norris, receivers of the Lehigh Valley Traction Company, have filed an answer to the allegation of the Easton (Pa.) Consolidated Electric Company, denying that in their management of the Lehigh Valley Traction Company they have in any way violated the lease of the Easton Company.

At the annual meeting of the Philadelphia Bell Telephone Company, the old board of directors was re-elected. The president's report shows net earnings for the year of $930,240. Dividends paid amounted to $852,367. Balance to profit and loss was $77,873. The number of stations in Philadelphia at the end of the year were 45,544.

The annual report of the Electric Company of America is expected to show net earnings for 1903 of $398,000, as against $349,000 the previous year, an increase of $49,000. It is said that the balance credited to the surplus of profit and loss account, after the payment of dividends, will exceed $600,000, against $453,000 the previous year.

The $5,000,000 refunding hundred-year 4 per cent. bonds of the Brooklyn Rapid Transit Company, application to list which was made last week to the Stock Exchange, and announced in ELECTRICITY, are not a new issue as was supposed by some at the time. They are the first bonds issued under the mortgage and were sold to Flower & Co. in May, 1902. They are not the bonds said to have had been hypothecated by the company recently for a time loan to carry on improvements. This loan amounts to less than $1,000,000.

VOL. XXVI. NEW YORK, MARCH 2, 1904. NO. 9.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office. - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

A So-Called Wireless Trolley System.

A recent article in a well-known New York daily paper, describing at considerable length a so-called wireless trolley system in operation in the south of Jersey, has a tendency to mislead the general public. The article says:

"A revolution in railway transportation will be achieved, it is believed, by the invention of a wireless trolley. In the new system the overhead or underground wires are done away with, as well as the third rail. The danger element is completely eliminated, it has been demonstrated, in doing away with these wires. The cost of installation and maintenance is enormously reduced. All that may be done with the ordinary trolley system as regards high speed and economy of transportation, it has apparently been shown, may be done better by wireless trolley."

Further on the writer of the article describes the system as follows:

"There is no slot with its underground wires, no third rail. Nor are the cars supplied with storage batteries. At intervals of 16 feet or more extending midway between the tracks is a series of little metal buttons, and that is all. The buttons rise only an inch above the surface of the street or road. One must look closely to see them.

"The system itself, however, is extremely simple. These inconspicuous little buttons are perfectly dead, electrically, until the car touches them. A powerful magnet carried beneath the car serves, however, to close the circuit beneath the metal buttons, whereupon the buttons become suddenly alive, giving what energy is needed to the car. The current thus picked up returns by the regular trolley rails, which thus complete the circuit. The instant the car has passed and the magnet has ceased to influence the metal button armature below the points of contact, the little metal button is left dead once more.

"The metal buttons are in reality the tops of airtight boxes sunk flush with the level of the street. The box itself is about 10 inches square and 2 inches deep. Their mechanism is extremely simple, and therefore unlikely to get out of order. These boxes placed at intervals of 16 feet are in turn connected by an underground conduit, which brings them all into the same circuit. This wire, it will be seen, is completely buried underground beneath the pavement of the street, so that its danger is absolutely nil."

From the above it will be seen that the word "wireless" is not the word to use in connection with this system. There is no such thing as a wireless trolley system in the sense of wireless telegraphy or wireless torpedoes. The trolley system described by the daily in question with a flourish of trumpets as "wireless," is nothing more nor less than an underground conduit system. There are several underground conduit systems in operation in this country and abroad, and about ten or eleven years ago the Patent Office in Washington was flooded with applications from inventors for patents on almost every conceivable idea for operating trolley cars without the conductors carrying the current being visible. Numerous patents were granted, but most of the systems proved defective when given a trial on a practical scale.

The Welding of Aluminum.

Mr. S. O. Cowper-Coles, at a recent meeting of the Faraday Society in London, introduced some notes on the subject of aluminum by showing that soldered aluminum joints

had proved unsatisfactory, as they will not stand the test of time, because galvanic action takes place between aluminum and solder. One of the chief difficulties encountered other than the formation of oxide in soldering aluminum is, that a few degrees below its welding point it passes into a pasty or brittle state, and being a very good conductor of heat, the solder rapidly cools and freezes before it has time to flow sufficiently. Reference was made to Dick's machine for welding aluminum by the removal of the oxide mechanically, combined with pressure; also to Heraeus' process, which consists in heating the aluminum in a reducing atmosphere until it reaches the pasty stage, when the joint is made by kneading and hammering. The electric welding of aluminum has not proved commercially successful.

The Schmidt electric welding apparatus consists of a carbon stick which is used in much the same way as a soldering iron, by being moved over the portion to be welded to remove the oxide, the aluminum forming one electrode, the carbon stick the other electrode. In Jones' machine for the welding of aluminum tubes, a strip of aluminum is wrapped round a mandrel, and the joints are fixed together by passing a low tension current through the portions to be welded.

Mr. Cowper-Coles described a process of his own which requires no flux or solder, and does not necessitate the hammering of the joint when in the pasty state, the process being especially suitable for wire, rods and tubes. The machine employed is fitted with clamping screws which are controlled by levers. The aluminum is heated by a benzine lamp, and when raised to the point of fusion, pressure is applied to the levers, which causes the aluminum to be welded to unite, a ring of metal being squeezed out.

This ring, which is largely composed of oxide, acts as an insulating and supporting collar, the molten metal being retained within it. Water is then projected on to the point by turning a handle at the same time a screen is moved in front of the flame. The rod is then removed, and when the collar is filed off the joint will be found to be as strong as the rest of the metal. A table was given showing the tensile strength of twelve consecutive welds; in all the tests the specimen broke at some distance from the weld, and in no case did it actually break through the weld.

Now that Mr. Cowper-Coles has devised a process for successfully welding aluminum, the future should see an increasing demand for this metal for long-distance transmission lines.

* * *

An Interesting Struggle.

In the course of a few years New York should abound in rapid transit facilities. We judge this from the fact that at a meeting last week of the Rapid Transit Commission the New York City Street Railway Company, which operates the Metropolitan system, submitted its plans for tunnel extension. The Interborough Company, which will operate the main subway, has already submitted plans to cover the same territory. Upon the inducements offered by both corporations will depend the decision of the Rapid Transit Commissioners as to which will be allowed to construct the new road.

The first mentioned company offers to build an electric railroad subway from the Battery to the Harlem River, touching the surface system at such important points as the new Pennsylvania Railroad station and the Grand Central station. The exact route of the Metropolitan's proposed tunnel is up Greenwich street, under Hudson street, under Eighth avenue, connecting with the Pennsylvania station tunnel at 32d street; thence across town, touching at 42d street, and under Lexington avenue to the Harlem River.

The extension proposed by the Interborough Company contemplates two branches. That on the east side is to connect with the present system at Park avenue, just south of 42d street, to run east to Lexington avenue, thence up Lexington avenue under the Harlem River. That on the west side will make a connection with the 42d street line, to run down Broadway to Union square, and thence south under University place, West Broadway and Greenwich street to the Battery.

The Interborough Company will give transfers from any part of its new subway to the elevated railroad at any point. The Metropolitan can perfect an elaborate system of transfers with its crosstown lines and can probably arrange for a cheaper fare over the lines of the Union Railway Company in the Bronx. As an offset to this the Interborough will probably have the advantage of Brooklyn extensions, which the Metropolitan does not yet possess. This will prove a strong argument in its favor, although the Metropolitan system of transfers in Manhattan will be able to touch more points than the Interborough can effect by means of the elevated railroad.

Whichever company finally wins out, one thing is certain—residents of Greater New York will get far better transportation facilities than they have had heretofore, and the city will get reasonable terms.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The London correspondent of the New York *Times* writes: "There are over 10,000 omnibuses in operation in London, which it is desired to put aside. What a field for an electric motor! The omnibus company does not care a fig what country furnishes the invention it earnestly desires to use in its great business. I wonder if an American cannot do the job!"

Prof. Dr. Markwald, of Berlin, is reported, according to a foreign contemporary, to have discovered a new radioactive substance, which he has named radio-tellurium. Before an audience of the leading scientists of Vienna, the professor said that in experimenting with pitchblende from Joachimsthal, Bohemia, he discovered minute quantities of a very active substance which at first showed all the reactions of tellurium, but further examination proved it to be a mixture of tellurium and most minute quantities of a substance hitherto unknown.

The Navy Department is making preparations to transfer the wireless telegraphy school for enlisted men from Newport, R. I., to the Navy Yard at this city, where better facilities are afforded for this work. It is intended to assemble here all men under electrical instruction, both in wireless telegraphy and other branches.

Architects and electrical engineers of Washington, D. C., held a joint meeting recently, and discussed questions of interest to both professions. Dr. F. A. Wolff, president of the Society of Electrical Engineers, occupied the chair and Philander Bettz acted as secretary. Six papers were read, showing the intimate connection between electrical engineering and architecture.

Additional discoveries of large deposits of rare earths and minerals containing radio-active preperties are reported from the Llano mineral district near Austin, Tex. Gadolinite and yttria are being mined there, and large quantities of the gadolinite is shipped East where it is utilized for making the filament or glower of incandescent gas burners and electric lamps.

MODERATE AND STEEP GRADES ON FOREIGN MOUNTAIN ELECTRIC RAILWAYS.

BY FRANK C. PERKINS.

Electrically operated railways having very steep grades are successfully operated in this country as well as in Europe without making use of the rack system. Electric power seems to be particularly well adapted to mountain roads the same as railways having frequent short steep grades to surmount. The cable railway has almost entirely given place to electric traction in cities even where the grades are very heavy. The polyphase alternating current system is used largely in Switzerland on the mountain roads both of ordinary track construction and using the rack system in extreme cases. The Jungfrau Railway has grades exceeding 25 per cent. which are easily taken at normal speed by the three-phase locomotives, and the Zermatt-Gornergrat Mountain Railway is another rack road which has grades of 20 per cent., the latter being 3,020 meters above the sea level.

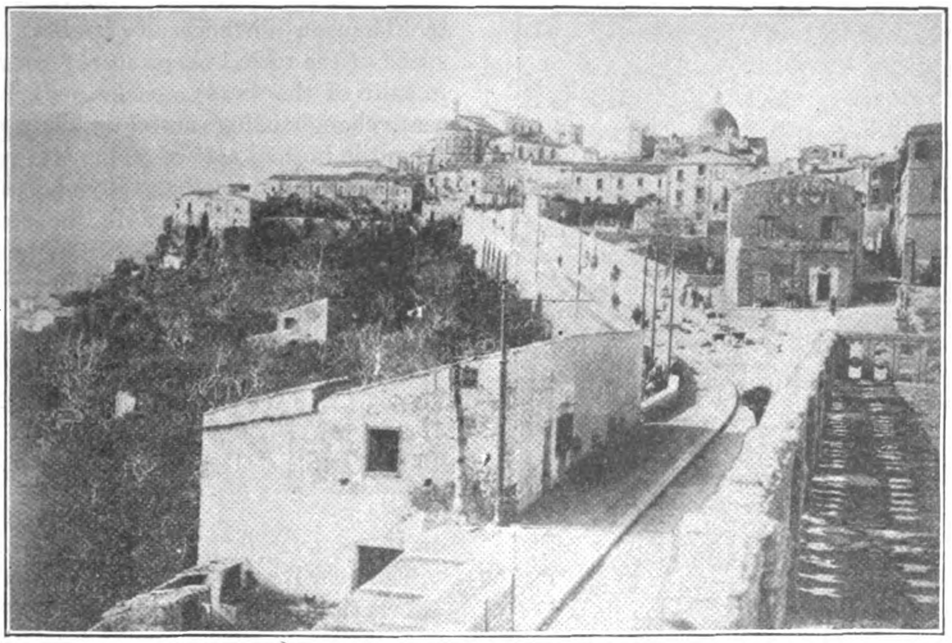

Fig. 1.—View of Palermo Electric Railway.

The accompanying illustration, Fig. 1, shows the moderate grade of the Palermo Electric Railway at Rocca Monreale. This railway was equipped electrically by the Schuckert Company of Nurnberg, Germany, who also supplied the high tension 20,000 volt generators at the power house at Morbegno which supplies three-phase current for the operation of the Valtelina Railway in Italy, shown in Fig. 2. The electric locomotives for this Italian railway were constructed by Ganz & Co. of Buda-Pesth, Austria-Hungary, and are of 600 hp. output and capable of handling trains of 200 tons on grades of 10 per cent. at normal speed without difficulty. These locomotives take the current from the overhead trolley wires at a pressure of 3,000 volts, this tension being obtained by means of step-down transformers, reducing the 20,000 volt transmission current to 3,000 volts for use on the working conductors.

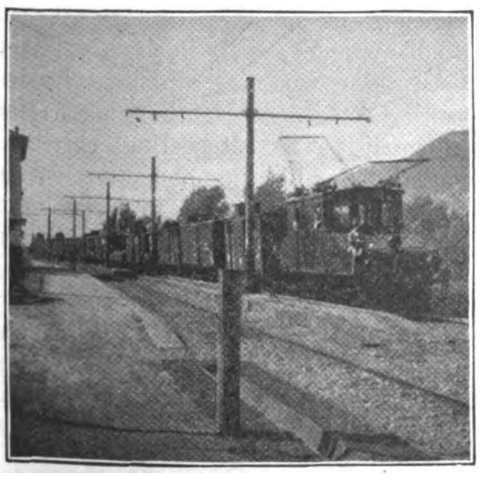

Fig. 2.—Electric Locomotive Freight Train on Valtelina Line.

The total length of the Valtelina Railway is somewhat more than 70 miles and both freight and passenger traffic are very heavy at certain seasons of the year. The normal speed of the freight and passenger trains is 18 and 36 miles per hour. In case an overhead wire is broken or if a section is intentionally cut out to prevent a train from passing, an automatic brake has been devised to stop the train at once. In case the trolley of the locomotive jumps the wire the pole is automatically drawn down immediately by the operation of an air valve which opens automatically and thus supplying the necessary power from the air compressor tank.

It is interesting to note that the track and line are entirely cut off from the 3,000 volt working current except at the time of the passage of the train, at all other times being normally cut out of circuit,

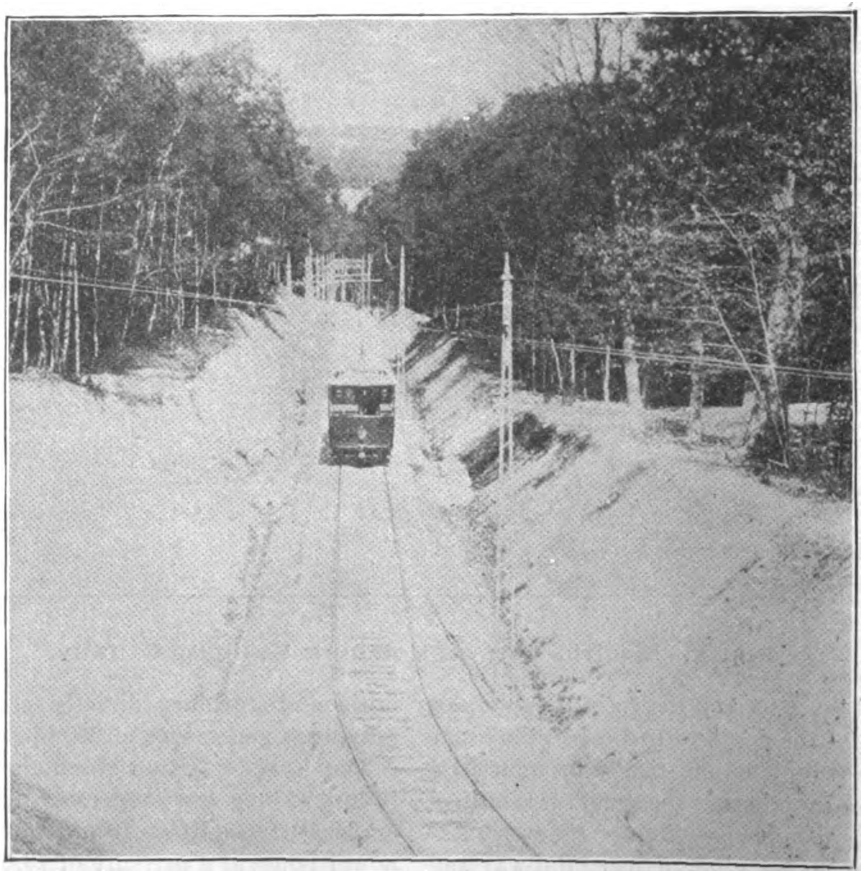

Fig. 3.--Electric Car on Homburg-Saalburg Line.

Unless the air brakes are in proper working condition it is impossible for the train to move for it is not possible to obtain current from the trolley wires unless the right air pressure is provided in the air brake cylinder, which allows the trolley poles to rise and meet the trolley wires to receive the current from the line. If a signal is set to stop the train it is impossible for the engineer to disobey the order as the train is automatically brought to a stop and the brakes set should it continue on the forbidden section.

The Stansstadt-Engelberg Railway and the Bergdorf-Thun Mountain Road in Switzerland were installed by Brown, Boveri & Co. of Baden, Switzerland. On the former line there is a particularly steep grade between the Obermatt power station and Grunwald and Evitement Cherst. The Stansstadt-Engelberg electric road is 22½ km. long and has three locomotives each equipped for the heavy gradient with two 75 hp. motors of the three-phase type. The current is supplied from a hydro-electric plant equipped with horizontal turbines directly coupled to polyphase generators of 600 hp. capacity

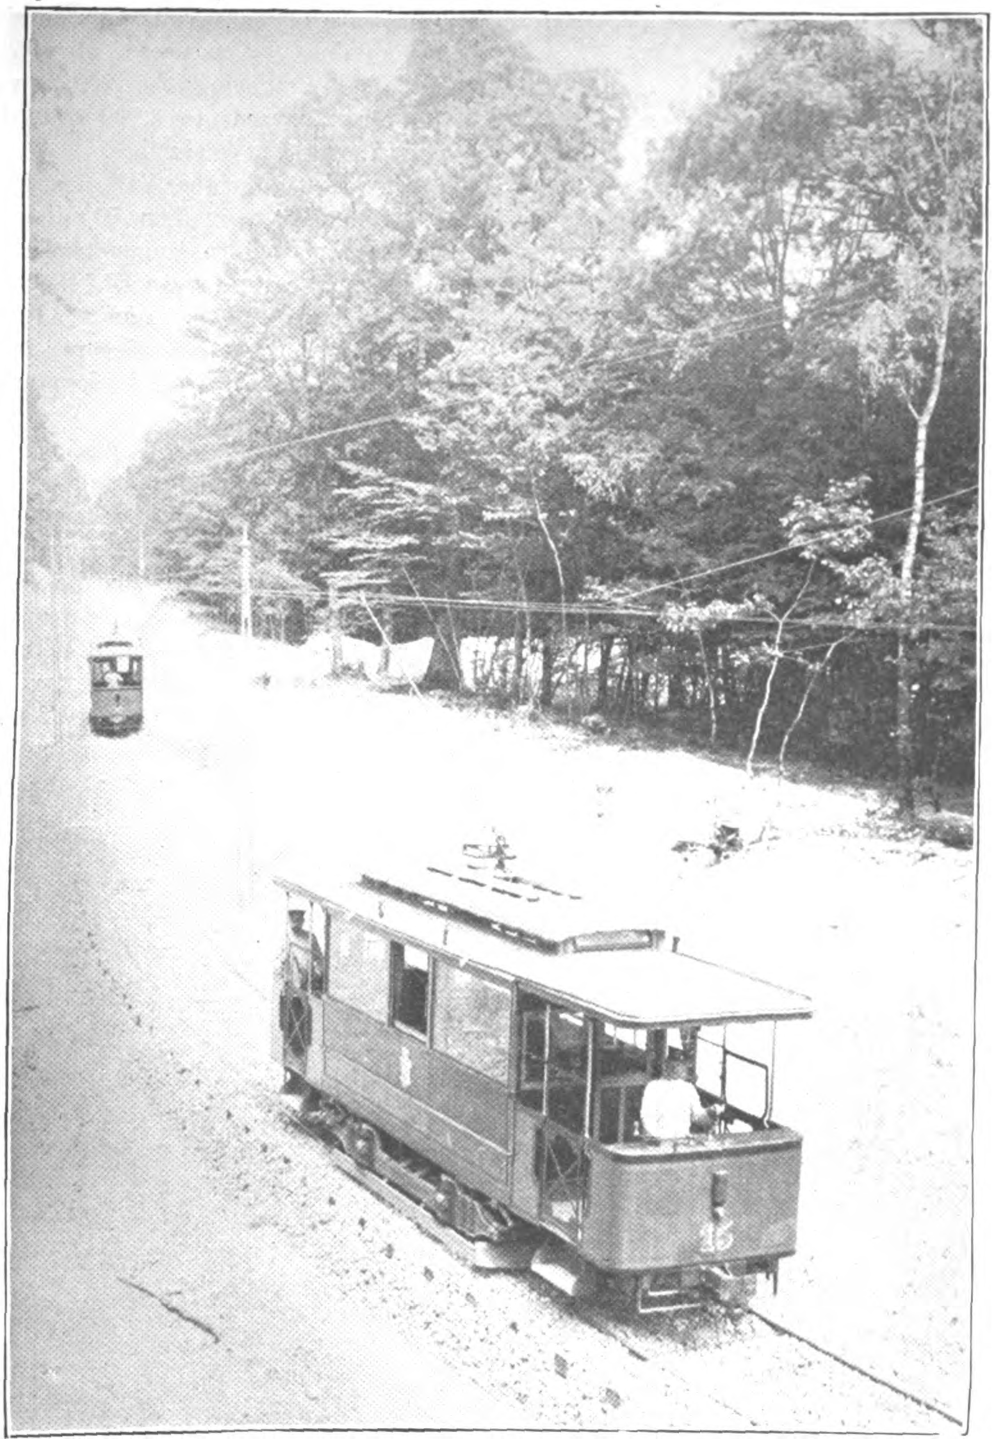

Fig. 4.—Electric Cars on Homburg-Saalburg Railway.

The Burgdorf-Thun Mountain Railway is 40 km. long and is operated by electric current transmitted from the Kander power house at a pressure of 16,000 volts. This high tension current is reduced at substations along the line to 750 volts for the overhead working trolley wires. The locomotives are equipped with two 150 hp. motors and are capable of hauling a maximum train weight of 70 tons up the steepest grade of 1 in 40 at half speed and a load of 50 tons at normal speed. The locomotive weighs 30 tons, making the total load 100 tons for the train. There is a continual up-grade the whole distance from Burgdorf to Gross-Hostetten., about 16 miles, and a heavy down grade to Thun, a distance of 9 miles. The speed of the train is kept nearly constant in spite of the heavy grades, only 2 per cent. change being noted on the grades from the normal rate of 39 km. per hour.

The Homburg-Saalburg Mountain Electric Railway is illustrated in the accompanying figures, 3 to 5, while Fig. 6 shows a car on a steep grade of the Elektrische Strassenbahn Heidelberg-Wiesloch.

DOUBLE CURRENT GENERATORS IN THEIR CONNECTION WITH DOUBLE CURRENT SUPPLY.*

BY W. L. WATERS.

The relative advantages of direct and alternating current supply are now pretty well known. The great advantage of alternating current is the ease with which high voltages can be handled and the facility with which the voltage can be transformed by means of stationary transformers. The chief disadvantage is that it is unsatisfactory for street railway work and for elevator and variable speed motors. With direot current, exactly the reverse is the case. It is unsuitable for high voltage work, but gives good results for all classes of motor work. The obvious result of this has been to have double current supply in situations where both these advantages and disadvatages are important. This usually means that in small towns alternating current is supplied for lighting and direct current for traction work, while in larger towns direct current is supplied for the downtown districts, where the motor load is important, and alternating current for up-town districts, where the load is almost entirely a lighting load. Thus we very often have both alternating and direct current supply from the same power station.

The question of double current supply from one station is usually settled by having both alternating and direct current sets, each set generally having its own engine. This solution is hardly regarded as satisfactory, because the motor load being a maximum load during

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

the day and a lighting load a maximum in the evening, it means that we have the alternating current sets idle during the day and the direct current sets idle in the evening, so that we have only about half the plant in use at one time. It is obvious that a saving in first cost and in operating expense will occur if the two systems are tied together in some way so that they can help out one another at times of heavy load. This can be done by having both an alternator and a direct current generator coupled to one engine, or by having double current generators, or by tying the supply circuits together by rotary converters, or motor generator sets.

From the point of view of the station engineer the double current generator ought to be the best solution. The efficiency is higher than when rotary converters or motor generator sets are used, and it ought to be considerably cheaper than either of the other methods. The main objection to it is that the voltage on the alternating current side of the machine bears a definite ratio to that on the direct current side, so that one can not be varied without the other, and that variation of the load on one side effects to a slight extent the voltage on the other side. The relative importance of these objections has, of course, to be decided in each individual case.

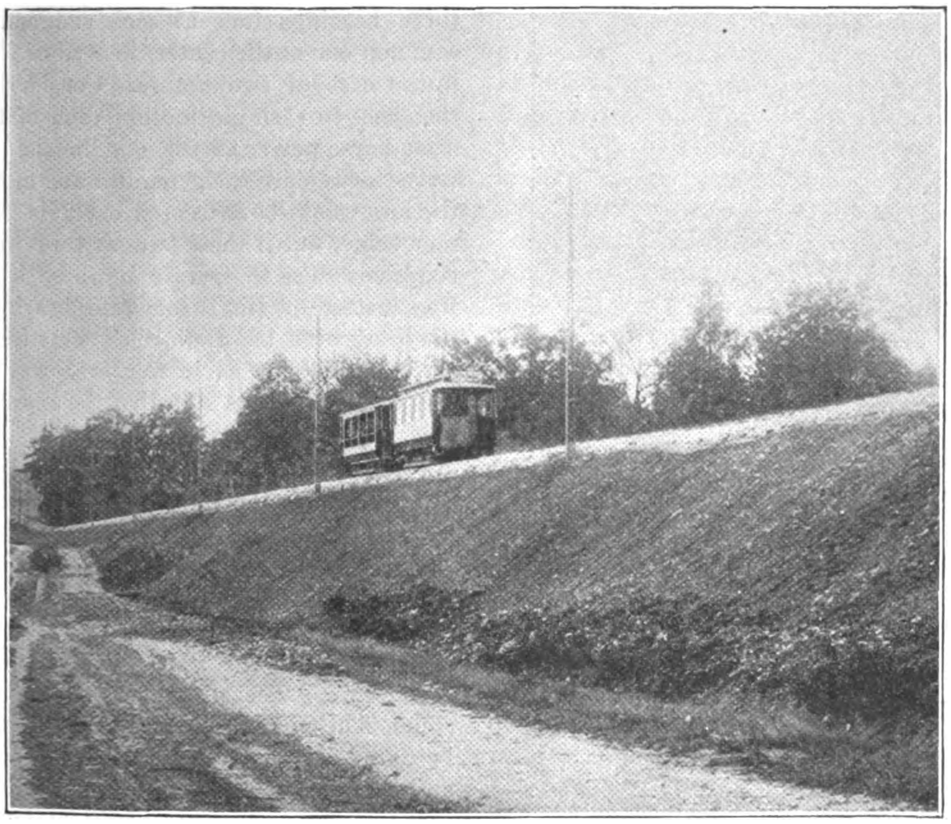

Fig. 5—Electric Cars on Steep Grade of Homburg-Saalburg Mountain Railway.

From the manufacturer's point of view the great objection to double current generators is that they are special machines and usually require new designs and special patterns and dies, and for this reason you will usually get very little encouragement from the manufacturer when you suggest double current generators, and if he takes the order at all, it will be at a fairly high price.

Of course, we can take any direct current machine and provide it with collector rings and get alternating current from it, but the difficulty is usually that the frequency is unsuitable. An alternator can be built for any commercial frequency and speed and voltage without any serious difficulty, but in a direct current generator, given the speed, voltage and output, the question of commutation and cost decide the number of poles, and hence indirectly the frequency. If this number of poles has to be changed considerably in order to obtain a different frequency there is often considerable trouble with the design, and this usually means increased cost. So if some latitude can be allowed in choosing the frequency and speed for the double current generators it is advisable to choose them so that, if possible, the generator does not differ very much from some standard direct current machine.

The following table gives the frequency of the alternating current that could be obtained from standard direct current generators. The number of poles, and the speeds of the machines are taken from those of the National Electric Company, but there is so little difference in these respects between the machines of the various companies that they can be regarded as applying to all standard makes of generators:

	Engine Type.		Belt Driven.		Steam Turbine Driven	
Kilowatts.	250 V.	500 V.	250 V.	500 V.	250 V.	500 V.
25	15	15	40	40	......	......
50	14	14	33	33	......	......
100	13	13	35	35	60	60
250	12	8	27	23	60	60
500	12	8	31	25	80	60
750	14	10	......	......	...	70
1,000	15	13	......	......	......	......
1,500	20	16	.....	......	......	......
2,500	22	18	......	......	......	......

If we took as standard frequencies for double current generators 25, 40 and 60, we see that some of these standard direct current generators could be very conveniently used as double current generators, with only a very slight change in the speed. A standard 2,500 kw. 250 volt engine type machine would make a very good 25 cycle double current generator, the only change being to provide the machine with collector rings, and to increase the air gap and put more copper on the field magnets in order to make the machine regulate properly when running as an alternating current generator. These changes would not increase the cost of the machine more than 20 per cent. On the other hand, if we took a 500 kw. 500 volt engine type machine it would mean very radical changes to make this into a 25 cycle double current generator. The number of poles would have to be increased from 10 to 24 or 30, which would mean nearly doubling the cost of the machine, but if we make this 500 kw. machine belt driven, instead of engine type, we can see from the table that a standard machine would give 25 cycles.

Twenty-five or forty cycle machines are not in any way difficult to build, at the most it is simply a question of special designs and patterns. But with 60 cycle generators we begin to have difficulties with the commutator on account of the high peripheral speed. Sixty cycle, 600 volt double current generators and rotary converters can be made to work, but they are not such reliable machines as those for lower frequencies, and there is no brush gear at present on the market which is quite satisfactory for the commutator peripheral speeds necessary in a 60 cycle 600 volt machine.

The higher the speed of a standard direct current machine of a given output the higher the frequency; thus we would expect that the higher the frequency of a double current generator the higher the

speed at which it should run, and it appears from the table that the most satisfactory 60 cycle double current generators will be those driven by steam turbines. Direct current generators suitable for being driven by steam turbines are not at present on the market, but in all probability they will be so shortly, and it looks as though they would solve the problem of 60 cycle double current generators.

Generally speaking, then, 25 cycle double current generators if of large size, can be direct connected to the engine, while for smaller than 500 kw. they are better belt driven. Forty cycle machines should always be belt driven if the cost is to be reasonable, while for 60 cycle double-current generators, apparently the only reasonable solution is to have steam turbine driven sets. Of course, double current generators can be made for any frequency and voltage up to 60 cycle 600 volts, and at any speed that you wish; it is simply a question of dollars and cents; but if you wish to get the most reasonable prices and the quickest deliveries and to have machines which when second hand will be worth something more than scrap, then you would be well advised to pay attention to the table of frequencies and outputs when laying out a station for double current supply.

It is claimed that a fair showing of success has been made by the only system of trackless trolleys in the United States, located at Scranton, Pa.

ELECTRICAL STATION PRACTICE.

ARTICLE XXVI.

BY W. H. RADCLIFFE.

In the two preceding articles have been shown the simplicity and efficiency of transformers for changing alternating currents of one voltage into alternating currents of a different voltage. It is also possible to alter direct current voltages in this manner, but instead of a stationary piece of apparatus simple in construction, there is required two rotary machines each of which approaches in complexity the average direct current generator in commercial use. In other words, there is required a motor-generator set, which as its name implies consists of two components—a direct current motor and a direct current generator each complete in itself but acting as a single machine owing to their respective armature shafts being directly connected and their respective field frames being mounted upon a single base.

Fig. 6.—Electric Car on Heidelberg-Wiesloch Line.

There is a similarity between the alternating current transformer previously described and this direct current transformer in that the function of the primary winding in the former corresponds to that performed by the generator of the latter. The line wires supply the primary current for running the motor, and the power derived from its armature is used to rotate the armature of the generator, which latter machine is designed to develop current at the desired voltage. Owing to the fact that the motor and the generator are in practice connected to entirely separate circuits, the ratio of transformation is not limited in any respect and may therefore be made whatever the existing conditions necessitate. There is, however, a certain loss in the process which is approximately equal to the loss occurring in two motors each having a capacity equal to that of the motor used in the set. This approximation is based upon the fact that direct current motors have usually somewhat lower efficiencies than those of direct current generators, while the friction loss of two motors operating singly would ordinarily be a trifle greater than that in a motor-generator set since in the latter machine there is usually three bearings (one at each end and a common one at the center) instead of four in the case of two motors. Considering then the two single motors each of the same horse power as the one in the set were to replace the generator and motor the loss would be increased over its former value, but if these two motors were combined so as to operate in three bearings instead of singly on four bearings, the loss would be diminished practically the same amount as it formerly was increased. It is thus seen that the approximation is not far in error.

Either the shunt or series wound type of motor may be employed at the power producing end of the set, but the field of the generator is either shunt or compound wound, depending upon whether or not it is desired to maintain or to raise the secondary voltage near full load. In either case a rheostat introduced in the shunt field winding of the generator will be found very essential. Both generator and motor are so mounted on the base that their respective commutators are at the outer ends of the set; by this means ample space surrounds all of the working parts, and repairs can readily be made.

Motor-generators are frequently used as boosters to raise or boost the voltage near the extremities of long distance, direct current, transmission lines. Of these, electric railway systems of moderate size in which it is desired to extend certain of the longer lines, form a typical example. Owing to the great cost of changing the system over to one employing alternating current, or storage batteries, or of constructing an additional power station, these solutions of the problem are usually at variance with good judgment and the amount of money at hand. The choice then remains between the purchase of additional wire for

feeders, the connection of a booster in the old feeders, or the installation of both larger feeders and a booster. Of these, it is generally found that either the second or the third mentioned alternative meets the conditions most satisfactorily.

A booster when installed in a railway system for the purpose just mentioned would have a series wound motor, and the circumstances to which it must conform would be as follows: The motor having a series winding, must provide for the full feeder current passing through both armature and field windings. Owing to the varying loads on a railway system due to the frequent starting and stopping of cars, the feeder current varies between zero and some such value as 150 amperes. This fluctuation of current through the field winding, will in ordinary cases vary the magnetization of the pole pieces from zero almost to the point of saturation; that is, the maximum feeder current will so nearly fill the magnet cores with lines of force that it would be quite difficult to cause more lines of magnetic force to pass through then. So long as the point of saturation is not reached, however, the proportion of amperes to field strength remains constant, and therefore the ratio of amperes to volts does not vary. The severe fluctuations of the feeder current would, if the motor were shunt or compound wound, cause most serious sparking and various other troubles, but in a series motor where the back ampere-turns on the armature that react on the field vary in precisely the same proportion as the ampere turns in the field, there exists at all times a tendency to balance the active forces and produce satisfactory operation. If, however, the field magnet cores are very large they cannot so quickly respond, magnetically, to changes in the strength of the current and there is therefore greater liability of the armature reaction momentarily weakening the field and thereby producing temporary sparking.

Motor-generators are not always composed of direct current machines, although when used as boosters on electric railway systems they must necessarily be of the direct current type. For other purposes, however, where direct currents of widely different voltages are to be obtained from an alternating current circuit and it is desired to install but one set, a motor-generator consisting of an alternating current motor such as the induction motor, and a direct current generator, must necessarily be employed. In such motor-generator sets it is not uncommon to find both motor and generator armature mounted on a common shaft and the respective field frames resting on a single base, although for connection on a very high pressure alternating current circuit separate armature shafts insulated from each other but directly connected together, and separate bases resting on a single foundation, are usually employed to afford the highest degree of insulation between the respective circuits of the two machines.

The commercial field that would naturally be covered by a motor-generator set composed of an alternating current motor and an alternating current generator, is far better supplied by a transformer such as was discussed in the two preceding articles. Since a transformer contains no moving parts it is simpler in construction, cheaper in price, and less liable to get out of order than a motor-generator; it is, therefore, used in place of a motor-generator whenever conditions necessitate the transforming of an alternating current of one voltage into an alternating current of a different voltage.

A machine performing the same function in a sub-station as a moter-generator transforming direct current of one potential into direct current of another potential, but of a more compact form, higher efficiency, simpler construction and less cost, is the dynamotor. A dynamotor differs from a motor-generator in that the motor armature and the generator armature are combined into one thereby requiring only one field frame. Since the motor and generator windings are mounted on a single core, the armature reaction due to the one winding is neutralized by the reaction caused by the other winding. There is, consequently, little or no tendency for sparking to occur at the brushes and they therefore do not need to be shifted on this account for different loads.

A dynamotor is usually constructed with two pole pieces which are shunt wound. Owing to the impossibility of having these pole pieces compound wound, the voltage developed falls off slightly under an increase of load, and herein lies one of the disadvantages of this type of machine. The armature, as previously stated, consists of two separate windings, one of which is joined to a commutator mounted on one side of the armature for motor purposes, and the other winding is joined to the commutator on the other side of the armature for generator purposes. By means of two studs of brushes pressing on the motor commutator, current from the service wires is fed into the winding connected to this commutator, and since the shunt field winding is also excited by the current from the service wires, there is developed in the generator winding on the rotating armature a direct electromotive force which is proportional to the speed of rotation of the armature in revolutions per second, the number of conductors in series which constitute the generator winding, and the total strength of the field in which the armature revolves. This electromotive force causes current to pass through the generator winding and the distributing circuit when the distributing circuit to which this winding is connected by means of its respective commutator, brushes, etc., is closed.

The dynamotor having shunt wound field magnets is connected at its motor end and started in precisely the same manner as any shunt wound motor on a constant potential circuit. The necessary precautions are, therefore, to have the poles strongly magnetized before passing current through the motor winding on the armature; to increase gradually the current through this winding, and not to close the generating circuit until normal conditions regarding speed, etc., are established in the motor circuit. Regulation of the current developed in the machine can only be obtained by the introduction of resistance in one or the other of the armature circuits, or by a shifting of the brushes around the commutator. As previously stated, however, dynamotors are more efficient than motor-generators of a similar type. This is owing to their having but one field circuit, and also on account of there being at least one less bearing, the dynamotor having but two bearings, whereas a motor-generator requires at least three, and occasionally where two entirely independent machines are directly connected together to form a motor-generator, there are four bearings.

RECTIFIERS.*

BY PROF. CHARLES F. BURGESS

(*Concluded from page 109.*)

While the efficiency of the rectifier is such as to enable it to compete very satisfactorily with a motor-dynamo or similar form of charging device when small outputs are required, for larger equipments of say 5 to 10 kw., the advantage or efficiency is in favor of the latter device.

The electrolytic rectifier will not operate indefinitely without attention, for there is a tendency to electrolytic decomposition, for the liquid to evaporate, and for the electrodes themselves to undergo

* Paper read at the twelfth annual convention of the Northwestern Electrical Association held at Milwaukee Wis., Jan. 20-22, 1904.

a certain corrosion which requires their replacement after certain intervals. With certain forms of cells, however, this corrosion and the amount of attention made necessary may be rendered so small as to offer little ground for practical objection.

In some extensive tests on a form of rectifier devised in our laboratory we have found that the total cost of maintaining the apparatus in working condition may be covered by a small fraction of a cent per kilowatt hour, and the amount of attention is limited to a few minutes once in each ten hours of continual operation.

Another limitation of the rectifier is due to the pulsating nature of the rectified current. Pulsations of the current while interfering in no way with its use for charging batteries or for other electrolytic work may produce a humming sound and heating due to eddy current in motors which are operated by this current. There is also produced a very undesirable humming sound in telephone lines which are operated from batteries simultaneously under charge by this pulsating current.

In measuring the efficiency, and investigating the properties, of this new type of apparatus certain peculiarities become manifest. On attempting to measure the output of these rectifiers by the use of direct current ammeters and voltmeters, and multiplying the readings thus produced to give the watts, a value considerably at variance with the true value may be obtained on account of the failure of the ordinary type of instruments to properly record the current having this peculiar pulsating nature. The wattmeter, however, will give more nearly correct indications and the efficiency should be properly determined by wattmeter readings on each side of the rectifier outfit. It might at first sight seem rather startling after measuring the rectified pressure by means of a direct current voltmeter and obtaining a reading of say 25 volts, to find that when connecting a 28 or 30 volt storage battery to the terminals, a charging current will flow. This, of course, is due to the fact that the voltmeter indicates only average values of current while at certain portions of the current wave the pressure considerably exceeds this value. It is while the pressure is at the maximum that the storage battery in the above instance will be charged.

Electrolytic rectifiers may properly be subdivided into two classes, one in which an aqueous solution is employed and another in which use is made of the non-aqueous or fused electrolyte. It has been found that certain soluble phosphates, borates, tartrates, sulphates and various other materials when placed in water to a suitable density will cause aluminum to develop the valve action. It has also been found that in most of these solutions if the temperature be allowed to rise beyond 30 or 40 degrees C a marked decrease in efficiency results, and it is, therefore, necessary in cells of any considerable size to use a cooling device in which the cell is kept at a low temperature either by flowing water or circulating air.

Mr. Carl Hambuechen, of the University of Wisconsin, has discovered that aluminum acts most efficiently as an asymmetric conductor when placed in molten sodium nitrate, or certain other similar salts. Upon this discovery is based the second class of electrolytic conductors, or those which employ the fused electrolyte. An average efficiency of from 10 to 30 per cent. higher than that of the aqueous type may be maintained with the fused salt on account of the more efficient valve action of the aluminum and the lower resistance of the electrolyte. It has a further advantage in that the development of heat is utilized, inasmuch as it tends to keep the material in a condition of fusion and at a high degree of conductivity, while with the aqueous type, the elevation of temperature beyond 30 or 40 degrees C. causes such a rapid decrease in efficiency that artificial means are necessary for dissipating the heat.

With the fused salt the temperature of operation is limited to the degree of heat at which evaporation and decomposition of the electrolyte begins, and this point being over 350 degrees C. allows a fairly high rate of radiation by simply exposing the cell to the air. This fact, together with the high conductivity of the fused salt, enables a large output per unit of weight and volume of the cell to be attained.

The essential parts of this rectifier consist in a specially wound transformer or auto-transformer which allows connection to a 110 volt or other convenient source of alternating supply. This transformer has various terminals by means of which the ratio of transformation and consequently the pressure of the rectified current may be regulated, thus avoiding rheostat control. Connections are made also from the windings of the transformer to two aluminum electrodes and an iron electrode. The electrodes are contained in an aluminum case surrounded by an asbestos cover, passing through and being held in place by a stone top.

When the rectifier is not in use, the electrolyte is perfectly solid and non-conductive, but by passing a low voltage and high volume alternating current lengthwise through the iron electrodes for four or five minutes the cell is brought into working condition, after which the heating current is switched off, and the cell is maintained at the desired working condition by the natural heat losses when operating within 25 per cent. of the normal load.

With aluminum electrodes 2 x 1 inch x ¼ inch, the normal load is 10 amperes, at a rectified pressure of 25 to 30 volts. The current may be several hundred per cent. higher than this value for a short time without detriment, and a 50 per cent. overload causes excessive heating and vaporization of the salt only after several hours run. The total weight of an output of this capacity is about 30 pounds, most of which is in the transformer.

All the attention which the device requires is the addition, once in each day of operation, of a small amount of salt in the form of sticks which are introduced through an opening in a stone cover. This salt is added for the purpose of supplying electrolyte losses by vaporization, and neutralizing the tendency of the electrolyte to become alkaline by the decomposition effect of the current.

By thus maintaining the salt in working condition, aluminum electrodes have been operated for over 800 hours without excessive corrosion and the iron electrodes last a considerably longer time. Estimates of the cost of the additional salt and the renewal of electrodes place the figure at below three tenths of a cent. per kilowatt hour.

The electrolytic rectifier in its present stage of development is an apparatus of interest and value to the central station manager as well as to the large number of customers who desire to obtain from existing alternating current systems current for their electric automobiles or for storage batteries used for other purposes.

If it comes into extensive use some interesting problems will be presented to the central station manager. The customer who connects his rectifier to the regular lighting circuits pays a high price for his power. It is doubtful whether even at this rate such a load is a desirable one from the station standpoint on account of its intermittent nature, and its interference with the regular lighting service. The management, however, could well afford to encourage the use of the rectifiers in the daytime to the extent of giving reduced rates for that portion

of the day when the tax on the lighting circuits is at the minimum.

The improvements in quality and price of storage cells, and the many new uses for them, tend to increase the importance of any device which will enable them to be charged from alternating circuits, and the rectifier may serve not only to add to the accommodation that can be offered to the customers, but also to afford an additional market for the central station product.

DASH POTS FOR CORLISS ENGINES.

ARTICLE I.

BY W. H. WAKEMAN.

The Corliss valve gear in operation never ceases to be a mystery to those who are not engineers or mechanics, especially the dash pots, which are frequently called pumps by people who know just enough about machinery to think they know a pump when they see one.

A dash pot slightly resembles a single acting pump, but there is a great difference between them in operation, for while the pump performs its useful work on the upward stroke, the dashpot does its duty on the downward stroke.

Dash pots increase the efficiency of every engine to which they are applied, and in modern practice they are not only an economical appliance, but an absolute necessity.

Fig. 1 illustrates a Corliss valve gear with dash pots in operation. The dash pot rod 2 is connected to the valve crank 3 and this crank has just been disengaged from the hook 4. The plunger in the cylinder 5 by means of the rod 2 draws the crank valve 3 to its lowest position, as shown, the instant that it is released from 4. When 3 is in the position shown the steam valve on the crank end is closed. There are two objects in using a dash pot, one of which is to close the cut-off or steam valve as soon as steam enough to complete that stroke has been admitted, and the other is to close it as rapidly as possible.

If an engine is run at a very slow speed it appears proper to close the valves slowly, but this is a mistake because the rate at which the valves close should be independent of the rate at which the piston travels.

When we consider the reason for opening and closing steam valves quickly, the reason for an independent rate will be apparent. When steam is wire drawn, or in other words, when its pressure is reduced by causing it to pass through a small passage, its efficiency is reduced. For this reason engine builders seek to admit steam as quickly as possible at the beginning of a stroke, and when enough has been admitted to cut off the supply as soon as possible. This is one reason for the economy of the Corliss engine in the use of steam.

The wrist plate motion opens the valves rapidly, the governor indicates the point at which steam shall be cut off and the valve crank is disengaged. The dash pot then performs its duty and the valve is closed quickly. Of course this action is repeated more times per hour where the speed is high, than in cases where it is low, but this is the only difference, so far as the prevention of wire drawing is concerned.

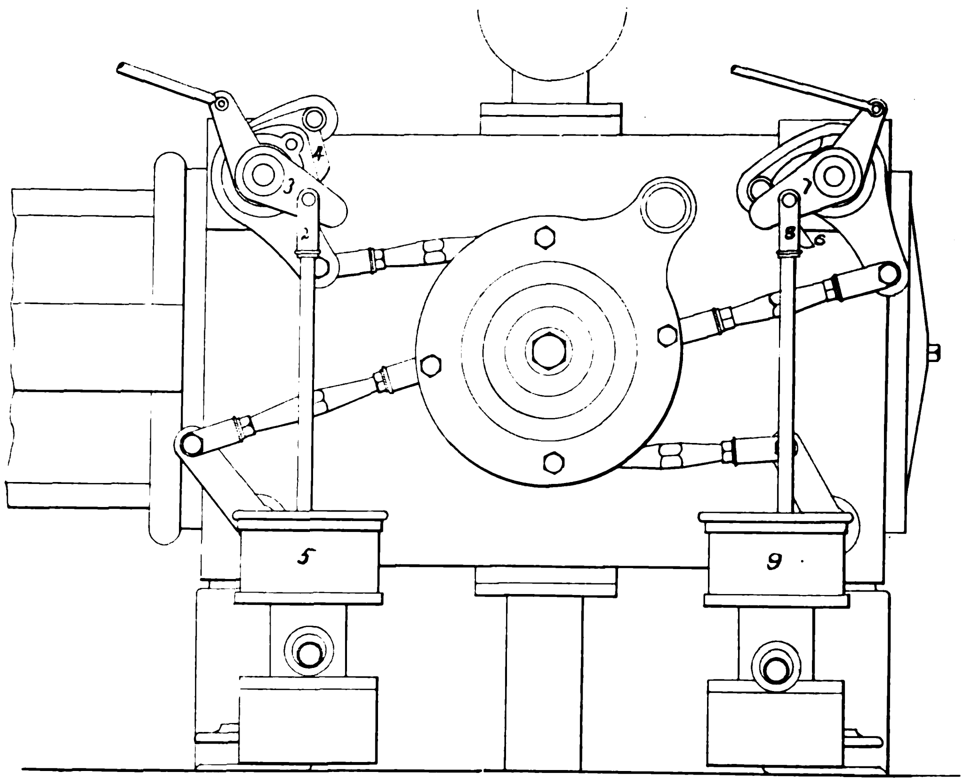

FIG. 1.

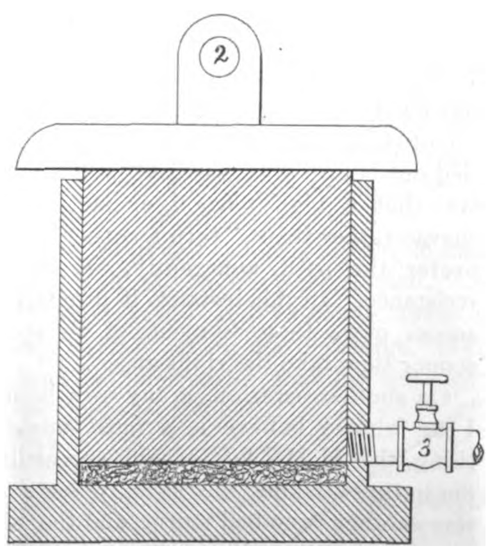

FIG. 2.

Again referring to Fig. 1, it will be noted that the dash pot plunger on the head end is also in its lowest position, corresponding to that of the other, but its relation to the wrist plate and its connections is far different.

The cross-head of this engine is traveling towards the cylinder, and the piston is near the cylinder head, therefore the crank end dash pot has been at rest for some time. The wrist plate has reversed its motion and is now traveling from right to left. The hook or latch 6 is about to engage the valve crank 7 and raise it together with the dash pot rod 8 from the position of rest which it now occupies. This will raise the plunger in the cylinder 9 until the valve is tripped, when this plunger will quickly close the valve and the operation is repeated indefinitely.

It was formerly considered that from 60 to 75 times per minute was the limit of speed at which a dash pot plunger could be made to operate, and when we consider the kind of dash pots they used (for lack of something better) its limitations are understood. By the use of improved designs and devices, the possible rate of operation has been raised to 200.

The lower rate is much more desirable from the working engineer's point of view, as the wear is much less and its action less noisy.

Fig. 2 is an old-fashioned dash pot that is still in use in the immediate vicinity of my engine room (but not in it) on an engine that was built in 1855 and is still doing good work. It rises and falls 67 times per minute.

The dash pot rod is fastened to the

plunger by means of a pin passing through 2 and the operation of this kind of a dash pot is as follows: As the plunger is raised by the valve gear, air rushes in through the valve 3, which is left partly open for this purpose, and fills the cylinder below the plunger. As soon as the crab claw, latch or hook (according to the style of engine) is unhooked from the valve crank, the plunger begins to descend, but it meets with some resistance, because the air below it cannot escape through the valve 3 fast enough to give it a free passage. It is therefore cushioned and brought to rest easily as a rule, but as a precaution against pounding, a piece of leather is fitted into the bottom of cylinder as shown in the cut.

A dash pot of this type, as made for practical use, never did close a valve rapidly, viewing the matter from a modern standpoint, and there is one reason why it never will.

It is possible to make a plunger heavy enough to drop very quickly, the instant it is released, but its great weight would make it impractical to start it from a state of rest, for it must be remembered that it is always started with a sudden jerk and not with an easy motion. Excessive weight here would cause excessive wear on the entire valve gear, making it noisy and liable to sudden failure when most needed.

LIGHTNING AT CLOSE QUARTERS.*

BY FRED. H. HADFIELD, M.I.E.E.

Possibly many others of our profession, readers of this, may have seen or experienced the awe-inspiring effects of lightning at close quarters; for myself, I have done so too often for my peace of mind, and in that country where its effects seem most marked—South Africa.

I have had the opportunity of seeing there, close to the Berg, the mountain range between Natal, and what used to be the Free State, the sky turn to a ghostly greenish hue, the wind rise in the space of a few minutes to a shrieking hurricane, almost overturning the post cart, and the thunder roar apparently in your very ears, while the lightning struck the ground and sent the boulders flying—a veritable inferno; while a short distance off it struck the trek chain of an ox wagon, killing every unfortunate beast.

And I have been nearer than this. Some years ago I had occasion to be working in a shop where I had a small steam engine running a dynamo and a line of shafting driving machine tools. As I wanted all the available power on the shafting, I went up to the roof to disconnect the coupling joining the two halves of the shafting, sitting on a plank while I took out the bolts. I had casually noticed that there was a storm about, but did not connect it with my present job. I had just finished disconnecting, and had levered back the coupling a couple of inches, sitting with my knees not 6 inches away, when, with a deafening noise, a most appalling flash passed across the gap between the coupling; the roar of the thunder, the noise of the falling iron chimney, the yells of some natives outside, and the sort of phosphoric stench one always gets on these occasions, came all together. I am not a particularly nervous subject at any time, and have been in peril of my life quite a dozen times, but nothing has so completely demoralized me as that flash. I absolutely had not the control of my muscles for some moments to remove myself from further danger.

I found the discharge had struck the iron chimney, riddling it with holes and knocking off the top length, gone through the iron roof, jumped thence to a large pulley, arched over the gap between the halves of the coupling along the shafting, thence to a 400-gallon iron tank outside full of water, and to earth through the water main.

On another occasion, many years ago, I had been inspecting a telephone, and a bad storm came on. I have found it convenient on these occasions to leave telephones alone, so I sat outside on the veranda watching the storm. The earth wire from the instrument was of stranded iron, and came out under the veranda and took a right-angled turn before going to earth. This was about 6 feet from me. Suddenly the lightning struck the iron rod on the roof carrying the insulator, demolished the telephone, and I saw carried out before my eyes the well-known law that a high tension, or static, discharge rather than "turn a corner," will prefer the path, apparently, of greater resistance. In this instance it discharged across more than 40 inches of air space sooner than take the right angle!

On another occasion, in my own house, I saw what I believe is a most unusual thing, that is, the fact of two succeeding discharges striking the same object. It was another very bad storm, and the sky was on this occasion quite green. The first flash struck the telephone, and I saw the light of the burning metal between the edges or chinks of the case. Almost instantly a second discharge struck it, blowing off the door and melting things up generally.

What I hope may make these remarks interesting to the "stay-at-homes" is the fact that in England one does not get opportunity of observing these intense effects, or at such frequent intervals as in South Africa, thus preventing them from studying these most interesting phenomena. For instance, it is intensely interesting to watch during a storm the discharges to earth through the Thomson magnetic blow-out arrester. I have fitted all the different patterns. I may say here that I do not believe that an arrester exists that will arrest at all times in our country, but the above are the best I know. You will see at times, for no apparent reason, that the flash and its consequent blow-out are instantaneous, too quick to follow; while at other times you may distinctly see the arc go up the horns until it breaks—blown out. Of course, on all occasions the dynamo current may not follow the lightning discharge, and be thus switched back again, as it were, but too many things happen at once on these occasions, and one cannot follow them all.

Another instructive object lesson I once appreciated. Some years ago there stood outside the Court House at Durban, Natal, a high flag-staff, with top mast. Steel wire ropes were carried down from the cross-trees to within 6 feet or 8 feet of the ground, where they were foolishly joined to the anchor plates by intervening rope lanyards. I saw the lightning strike this. Of course, it could only pass to earth over the wet ropes, and the result was an awful smash up.

Last, but not by any means least, I may add the following: I came home in 1889 principally to see the Paris Exhibition, and on my return voyage in November of that year, our vessel ran into the most awful storm it has been my fate to experience at sea. It commenced before we rounded Ushant, did its worst in the Bay, and followed us for eight days. At its height I saw then for the first, and I earnestly hope for the last time, luminous balls of fire on each masthead—St. Elmo's fire, so called. The marvelous grandeur, of such a storm one cannot dispute, in spite of physical discomfort; the inky blackness of water and sky, the white flying spindrift, the laboring vessel wallowing in the waves coming in hundreds of tons over her bows, in spite of her engines running only quarter speed, the howling hurricane and almost continuous lightning, and calmly sitting above all this disturbance these mystifying luminous spheres. Whatever they may be or how producea, it seems to me that the old seaman shaking his head at them is as

*From the "Electrical Review," London.

wise or as ignorant as the rest of us. On this occasion and others I should have revelled in the companionship of the crank who so constantly rams it down the throats of the reading public that no waves ever exceed 40 feet in height. I am inclined in my vanity to think that the gentleman in question has not made the acquaintance of a genuine cyclone.

A real No. 1 grade cyclone I had the pleasure of sampling blew down the registering anemometer after it had recorded a speed of some 90 miles per hour, thus leaving the calculation of its eventual speed to the imagination. It held the writer in the angle of a building as fast as if he had been nailed, while the neighboring trees and iron roofs "went by the board." The sea came up on the land, verandas, iron roofs and house fronts were swept away, and a warehouse belonging to a shipping firm collapsed like a house of cards—walls, roof, woodwork and contents in a heap. Most of the lightning display on this occasion occurred within the electric lighting station, which fed a lot of overhead mains, which were swept away lock, stock and barrel, while the engineer in charge endeavored to shut down engines and switch off circuits with feet as well as hands, and wished for the nonce he had been endowed like the centipede.

Another Electrical Invention.

A dispatch from Chicago says the "noiseless court," an electrical invention, was announced Saturday night at the banquet of the Northwestern Association of the Massachusetts Institute of Technology. The announcement was made by Prof. W. Elwell Goldsborough, of Purdue University, head of the electrical exhibit at the Louisiana Purchase Exposition.

The invention is the production of J. F. Hutchinson, an electrical engineer of New York, who has been in St. Louis for some time working out the details. The device is of such a nature that no sound is heard by a person standing within the court until an ordinary telephone receiver is placed to the ear. Then not only the sounds in the court become audible, but also conversations which may be going on over nearby telephone wires.

It is stated that by means of the "noiseless court" conversations between points hundreds of miles distant from each other will be made audible within the court.

The exact nature of the device is not revealed. The news of its success was received by Prof. Goldsborough less than an hour before the banquet.

An Energetic Sales Manager.

Mr. I. A. Bennett, general sales manager for the Electric Appliance Company, Chicago, has resigned his post which took effect March 1, and will open the Chicago offices of the Phelps Company of Detroit, Mich., manufacturers of the Hylo turndown lamps and other specialties. Mr. Bennett resigned a position that he held with the Electric Appliance Company for a considerable length of time, having served with this company for about eleven years, having previously been connected with the Ansonia Electric Company.

MR. I. A. BENNETT.

Mr. Bennett's energetic push as a sales manager and originality as an advertising man has made him one of the best known men in the electrical business, and he is receiving congratulations on all sides on his entrance into a field which promises very handsome returns. He has also accepted the presidency of the Central Station Publishing Company, which is being formed for the promotion of central station advertising.

His offices will be located in the Monadnock Building, Rooms 529 and 530. He will carry a full and complete stock of every style, base, and voltage, Hylo lamps and specialties, making shipments from Chicago stock.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED FEBRUARY 23, 1904.

Electric Railways and Appliances.

752,719. Automatic Signaling System for Electric Railways. Harry B. Snell, Cement City, Mich., assignor, by direct and mesne assignments, to the Snell Electric Signal Company. Filed July 17, 1903.

752,737. Trolley. Thomas F. Wetton, Newark, O., assignor of one-half to Charles E. Krebs, same place. Filed Oct. 27, 1903.

752,812. Electric Block-Signal System. Charles W. S. Turner, Mountville, Va. Filed April 3, 1903.

752,822. Alarm-Signal for Railway-Trains. Hugh E. Butler and Joab L. McCollum, Atlanta, Ga. Filed Nov. 12, 1903.

752,824. Electric Railway Switch. Harry H. Chandler, Waltham, Mass. Filed Oct. 24, 1903.

752,839. System of Electric Train-Lighting. David C. Henry, Denver, Col., assignor to Henry Electric Equipment Company, same place. Filed Sept. 23, 1901.

Electric Lights and Appliances.

752,865. Electric-Arc Lamp. Carl Schuster and Christian N. Bergmann, Pittsburg, Pa. Filed March 20, 1902. Renewed July 18, 1903.

753,134. Electrical Illuminating Device for Show-Windows. John H. Goebst, Chicago, Ill. Filed May 6, 1903.

753,138. Portable Electric-Lamp. Harry C. Hubbell, Brooklyn, N. Y., assignor to Horace W. Fuller, New York City. Filed July 2, 1903.

Electrical Machinery and Apparatus.

752,643. Electric Pump for Switching Mechanisms. Walter J. Bell, Los Angeles, Cal., assignor of one-half to Leon F. Moss, same place. Filed July 31, 1903.

752,691. Inductor-Alternator. Leon J. Le Pontois, New Rochelle, N. Y. Filed Aug. 22, 1903.

752,692. Polyphase Magneto-Alternator. Leon J. Le Pontois, New Rochelle, N. Y. Filed Nov. 7, 1903.

752,820. Dynamo-Brush. Max Bunnig, Gardelegen, Germany. Filed Oct. 5, 1903.

752,858. Electromagnetic Switch Device for Apparatus for Magnetically Recording and Strengthening the Reproduction of Speech, etc. Peder O. Pedersen, Copenhagen, Denmark. Filed June 21, 1901.

752,953. Transmission-Gear. Alanson P. Brush, Detroit, Mich. Filed Oct. 11, 1902.

753,191-192-193-194. Electric Meter. Thomas Duncan, Chicago, Ill. Filed July 11 and 18, 1901; Oct. 23, 1903, and Jan. 2, 1904.

Telephones and Telephone Apparatus.

752,649. Telephone Attachment. George B. Buchanan, Haverstraw, N. Y. Filed Sept. 15, 1902.

752,710. Means for Synchronizing the Instruments of Telephone Systems. Hope Redmon, Rufus L. Hope and Robert H. Conway, Cynthinia, Ky. Filed Sept. 17, 1903.

752,722. Switchboard. Alfred Stromberg, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company. Filed May 13, 1902.

752,761. Multiple-Switchboard System. William M. Davis, Chicago, Ill., assignor, by mesne assignments to the Stromberg-Carlson Telephone Manufacturing Company. Filed Dec. 7, 1900.

752,909. Telephone Signaling Mechanism. Oscar O. Lee, Chicago, Ill. Filed Jan. 11, 1900.

753,067. Telephone or Telegraph System. Robert Hamton, Milton, Mass. Filed Feb. 10, 1903.

753,183. Telephone Selecting Device. William D. Watkins, San Jose, Cal., assignor to the Watkins Manufacturing Company, San Jose, Cal. Filed Aug. 29, 1902.

Miscellaneous.

752,652. Electrical Apparatus for Registering the Discharge of Liquids by Pumps. Hans J. S. Cassal, London, Eng., assignor to the Liquid (Electric) Register Sydicate, Limited, same place. Filed March 17, 1903.

752,689. Electrically Propelled Vehicle. Louis Krieger, Courbevoie, France. Filed Feb. 26, 1903.

752,696. Electric Cord Adjuster. Jonathan E. Masterson, Spokane, Wash. Filed May 23, 1903.

752,705-752,921. Audiphone-Receiver. Hermann G. Pape, Brooklyn, N. Y., assignor of thirty one-hundredths to James McVey, New York City. Filed Oct. 21, 1902, and Sept. 13, 1902.

752,834. Electrical Receptacle. Philip H. Fielding, New York City. Filed June 27, 1903.

752,840. Flexible Conducting-Cord. Howard B. Holmes, Evanston, Ill., assignor to the Western Electric Company, Chicago, Ill. Filed Jan. 27, 1902.

752,843. Signaling Apparatus. Robert B. Kernohan, Pittsburg, Pa. Filed May 23, 1903.

752,894. Selective Signaling. Reginald A. Fessenden, Fort Monroe Va., assignor by direct and mesne assignments, to the National Electric Signaling Company. Filed Dec. 29, 1902.

Removal Notice.

The Western Telephone Manufacturing Company has leased quarters in the Atlantic Building, 42 West Jackson Boulevard, Chicago, Ill., and will move its factory and office to this address March 5.

THE TELEPHONE WORLD.

Iowa Telephone Association.

The eighth annual meeting of the Iowa Telephone Association will convene in the "Ordinary" of the Savery House, Des Moines, on Tuesday, March 8, at 2 P.M., for a three days' session.

The following is an outline of the programme: President's Address; The Farm Line Proposition; Operating a Telephone Plant as a Side Line; Long Distance Lines; Jealousy Among Independent Telephone Men; Shall we Establish a Clearing House; Automatic Apparatus from the Standpoint of Service and Operating Expense; Our Business Relations; Leased Toll Lines; How Can We Promote Better Feeling Among Toll Operators, Inducing Harmony, Improving Car Service, and thus Reducing the Lost Call Record; Necessity of Uniformity in Toll Line Service and Rates; Our Loyalty to the Principles of the Association.

The Michigan State Telephone Company, the successor of the recently reorganized Michigan Telephone Company, announces the election of directors and officers as follows: Directors—W. C. McMillan, T. H. Newberry, John T. Shaw, Henry Russel, Frank J. Hecker, A. E. F. White, Elwood T. Hance, all of Detroit; Lewis H. Withey and Dudley E. Waters, Grand Rapids; N. W. Harris, W. A. Jackson and A. G. Farr, Chicago; Isaac Sprague and F. A. Farrar, Boston; Allen B. Forbes, New York. Officers—W. C. McMillan, chairman executive committee; W. A. Jackson, president; T. H. Newberry, vice-president; Elwood T. Hance, secretary; John T. Shaw, treasurer; N. W. Harris, chairman of board; L. C. Krauthoff, general counsel; Elliott G. Stevenson, attorney. The active management will be under the supervision of Mr. Jackson, president, and the executive committee of which Mr. McMillan is the chairman.

At a meeting of the citizens of the town of Boston, N. Y., for the purpose of organizing a telephone company to connect Boston and Hamburg, the following officers were elected: President, Fred Frank; vice-president, Philip D. Weber; secretary; Frank X. Weber; treasurer, Edward Heinrich; electrician and collector; Jacob Brodbek. The organization will be known as the Boston Valley Telephone Company. It expects to begin operation as soon as the frost is out of the ground.

The Central New York Telephone & Telegraph Company, embracing St. Lawrence, Jefferson, Hamilton, Lewis, Herkimer, Oneida, Madison, Onondaga, Chenango, Otsego and Delaware Counties, and the Empire State Telephone & Telegraph Company, embracing Oswego, Cayuga, Cortland, Seneca, Wayne, Ontario and Yates Counties, have united.

President Wheeler of the Illinois Tunnel Company is quoted from Chicago as saying that the company now has installad nearly 6,000 telephones in the down-town district and will have 10,000 in service by July 1.

The Southwestern Telegraph & Telephone Company is about to expend $80,000 in extending and improving its system in San Antonio, Tex.

New York Ahead of London in Telephones.

A dispatch from London says an interesting comparison of English and American telephone systems, made recently, shows London to be a long way behind New York.

In the latter city, an area of 429 square miles, with a population of 4,000,000, as against London's 640 square miles, with a population of 6,500,000, is covered with no less than 200,000 wires, while London, including the 15,000 post office lines, can only boast of 80,000.

Despite this big difference and the fact that London pays a proportionately heavier rate the service on this side leaves very much to be desired, and, as regards efficiency, it certainly is not to be compared with New York

---

The Big Eddy Telephone Company was lately incorporated in Albany, N. Y., to operate in Orange and Sullivan Counties and in Pennsylvania: Its capital stock is $8,000, and directors: Frank Kinnie and G. W. Engleman of Narrowsburgh, and M. G. Noble of Calkins, Pa.

It is declared that the Syracuse, N. Y., Telephone Company is to branch out considerably. Joseph J. Jermyn of Scranton, Pa., president of the company, has recently been completing arrangements for a bond issue of $400,000 to practically reconstruct the company's system.

The Electric 'Phone Company of Stewart, Minn., has filed articles of incorporation with the Secretary of State. The capital is $25,000, and the incorporators are Henry E. Poseley, Edward N. Sckmidtz, Edward Reinhardt and A. Schmidtz.

The Maryland Telephone & Telegraph Company has succeeded in installing more than 1,000 new telephones since the fire, and of this number 800 have been given to old subscribers, who were forced into new places of business.

The Indian Territory Telephone Company, with headquarters in Vinita, has just completed a line from Tulsa to Muskogee. The line runs parallel to the Missouri, Kansas & Texas Railroad between the two towns.

The farming community east and north of Summitville, Ind., in Boone and Van Buren townships, is to have a new telephone system. Robert W. Inglis, of Summitville, having been granted a franchise by the county commissioners.

Articles of incorporation have been filed by the Phelps County, Neb., Telephone Company, which has a capital stock of $40,000. The incorporators are C. W. Stiger, C. C. Fansburg, J. F. Butterfield and F. W. Barber.

The Delaware & Atlantic Telephone Company has raised its rates at the Cape May County, N. J., seaside resorts.

The Farmers' Mutual Telephone Company of Tonkawa, Okla., has filed an increase of capital stock from $2,500 to $10,000.

The Central New York Telephone Company 's planning to make Syracuse instead of Utica its headquarters.

Constant Increase of Telephones.

At the convention of Independent telephone companies in the Ohio Valley, which convened in Cincinnati recently with over 100 exchanges represented, a paper was read by J. B. Hoge of Cleveland, on the "Independent Telephone Situation." He said in part:

"When the Bell patents expired nine years ago there were less than 300,000 telephones in operation, and now there are millions. Last year more than 1,000 Independent telephone companies were organized in the United States, or over two a day. In four years the Independent long-distance lines have grown as rapidly as exchanges.

"The farmer's life has been revolutionized, especially in little exchanges, giving them connection with the post office and county seats.

"The through business is handled the same as coupon tickets are sold over the railroad and freight is billed over various lines. There are to-day over 2,000,000 Independent telephones in operation in the United States, and 1,000,000 Bell telephones, and the business is yet in its infancy."

A. W. Carter of Grenada, Miss., who owns and operates a long-distance telephone line between that city and Eupora, has been in the latter place investigating the practicability of establishing an exchange there. The project met with much encouragement on the part of the business men and citizens and a considerable list of subscribers was soon secured. Application will be filed soon asking for a franchise, and this doubtless will be granted by the board of aldermen. The enterprise will be pushed to completion as soon thereafter as practicable.

It is understood upon good authority that the Hyden Telephone Company has now been organized and will soon begin the construction of a telephone line from Barboursville to Hyden, Ky. The men interested in this enterprise are R. M. Jackson, A. B. Eversole, Abner Asher, John Woodward and Judge H. C. Faulkner. Mr. Jackson will be treasurer and Mr. Woodward manager, but the president has not been decided upon. An exchange will be put in at Manchester and branch lines will be run out to various points in Clay and Leslie Counties.

Telephone Incorporations.

The Waldo Home Telephone Company, Waldo, O. Capital stock, $25,000. Incorporators: William Klingel, M. Lewis, A. Oborn, W. P. Kraner and Sam Schrader.

The Liberty Center Telephone Company, Liberty Center, Ind. Capital stock, $2,500. Incorporators: James P. Mounsey, Lewis A. Minniear, Orin D. Garrett, Joseph Stahl and George M. Gavin.

The Hamilton County Independent Telephone Company, Webster City, Ia. Capital stock, $24,000. Incorporators: D. C. Chase, J. W. Lee, Chris. Williams, Sam Sweedland and C. L. Poland.

The Pilot Mound Farmers' Mutual Telephone Company, Pilot Mound, Ia. Capital stock, $10,000. Incorporators: William Larson, O. W. Hinman, George O. Durrell, George Owen and L. A. Carlson.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Anadarko, Okla.—At at election held here recently $50,000 in bonds was voted for the construction of sewers and a municipal electric lighting plant.

Anniston, Ala.—A. H. Quinn and associates have asked for a franchise here to build and operate an electric light and power plant.

Beloit, Wis.—The city council has advertised for bids for a municipal electric light plant.

Cambridge, O.—The Cambridge Electric Light & Power Company was lately incorporated for $500,000 by R. V. Orme, O. H. Haber and W. Moss.

Carroll, Ia.—A. Brown has purchased J. W. Kennebeck's interest in the electric light and heating plant, and is now sole owner. Plans are being prepared for the improvement of the plant. Three new boilers, a new engine and a new dynamo are among the equipments so far decided upon.

Dover, Del.—W. H. Walker, mayor, states that this city will probably have to extend its electric plant within the next four months. The electric light and water committee has charge of asking for bids.

Frankfort, Kan.—The citizens are agitating the question of erecting an electric lighting plant.

Fort Branch, Ind.—As soon as the weather permits work will begin on the new electric lighting plant here.

Hannibal, Mo.—The city council will soon employ a constructing engineer to draw plans and specifications for the new electric light and power plant here.

Jasper, Ind.—This town proposes to purchase the electric light plant, and put in a power house of sufficient capacity to furnish the town and private business houses, etc.

Jefferson, Tex.—The city council has granted a new franchise for an electric and gas plant to a Chicago company.

Lena, Ill.—This town is agitating the question of erecting an electric light plant to cost about $10,000.

Maynard, Minn.—The citizens are agitating the question of building an electric light plant.

Montague, Mass.—The stockholders of the electric light company have voted to buy a storage battery.

Monticello, Wis.—E. L. Babler is interested in the proposed electric light plant.

Mooresville, Ind.—The Public Service Company, recently incorporated with $50,000 capital, will erect an electric light plant and waterworks here. W. B. Vestal and B. V. Hubbard are interested.

Mountain View, Mo.—Williams & Co. are contemplating putting in an electric light plant shortly.

North Vernon, Ind.—A movement has been started to enlarge the electric light plant here.

Ogden, Ia.—This town will receive sealed bids until March 15 for the construction and all the material necessary for an electric light plant. William Bakely, mayor.

Omro, Wis.—The Omro Electric Light Company has been incorporated with a capital of $10,000 by J. Challeny, J. S. Lighten and others.

Stoughton, Wis.—The citizens will soon vote on building a new municipal electric lighting plant.

Uvalde, Tex.—This city is to have electric lights. W. H. Rose, the owner and manager of the new gin here, is making arrangements to put in the plant at an early date.

Waterville, Kan.—An electric light plant is to be installed here.

Woonsocket, S. D.—A company composed of local business men has secured a 20-year franchise for an electric light and heating plant. The franchise requires work to be commenced April 15.

STREET RAILWAYS.

Asbury Park, N. J.—The Seacoast Traction Company has been formed to construct a trolley line to Sea Girt. connecting at Belmar with the Atlantic Coast line from here. The officers of the company are. President, Charles L. Spier of New York; vice-president, E. V. Patterson of Spring Lake; secretary, R. E. Rafferty, and treasurer, I. K. Harrison, both of New York.

Baraboo, Wis.—W. J. Bell, former manager of the Baraboo Telephone Company, is endeavoring to interest business men in an electric line to extend from here to Grand Rapids.

Bloomington, Ill.—There is a project on foot whereby the Reed Investment Company of Colorado Springs, Col., may take up the work of a new electric line from Peoria to this city. —W. H. Knight has secured the right of way for an electric line between here and Decatur.

Chippewa Falls, Wis.—The Chippewa Valley Electric Railway Company has decided to make a bond issue to extend its lines.

Denver, Col.—The Bear Lake Valley Railway & Electric Company was lately incorporated, capitalized at $100,000. H. E. Slusser and M. Smith are among the directors.

Durand, Mich.—The common council has granted a franchise to build and maintain an electric railway in this village to J. D. Leland.

Edmonton, Can.—The council has accepted the plans of W. G. Trethway, promoter, of Montreal, for an electric street railway.

Elwood City, Pa.—The Wayne Electric Street Railway Company will build a road from this city to Park Gate. Its capital stock is $6,000. H.S. Blatt is president.

Franklin, Pa.—Pittsburg capitalists, headed by J. W. Boileau and W. S. Ravenscroft, will build a new trolley line from here to Butler.

Hamilton, Ont.—The city clerk has received notice from Wallace & Little of Woodstock that they will apply for a Dominion charter for an electric railway to run from this city to Brantford.

Hillsboro, Ill.—The Hillsboro Electric Company has been incorporated with a capital of $15,000.

Kankakee, Ill.—The Kankakee Interurban Riverview Railway Company will present a petition to the president and board of trustees of the village of Waldron for the consent to construct, operate and maintain an electric street railway.

Lexington, Ky.—The Blue Grass Traction, which operates a line from here to Paris, Ky., and the Lexington & Georgetown Traction, which operates a line from this city to Georgetown, have been consolidated with Yunger Alexander as president. A. S. Rice, vice-president of the Equitable National Bank, is to be the treasurer and secretary. The capital stock will be $750,000. The stock in both companies is owned practically by the same men.

Louisville, Ky.—The line of the Kentucky Traction Company is to be built from this city to Nashville at once.

Macungie, Pa.—The Allentown & Reading trolley line will be extended to this place.

Minneapolis, Minn.—The Minnesota Power & Trolley Company is the name of the new company which proposes to build new electric railroads. It is said one will run from here to Stillwater.

Mount Holly, N. J.—The Burlington County Trolley Company is considering the propriety of extending its road from this place to Pemberton by way of Smithville.

Ottawa, Ill.—The McKinley Syndicate may build electric roads in Cuba.

Philadelphia, Pa.—The Wilkins & Braddock Electric Street Railway Company has been incorporated with a capital of $21,000. H. McKinney is president.

Sacramento, Cal.—Israel Meyers is the promoter of the Sacramento, New Castle & Oroville electric road.

Wabash, Ind.—The Wabash & Rochester Railway Company is going to introduce the Pullen or wireless system in the construction of its road in Indiana. All overhead wires are abolished and the cars are impelled by a system of magnets. The roadbed is provided with a series of specially constructed tubular armatures. adapted to be energized by magnets upon the car, by which they will close automatically for a period corresponding to the time the car is over them.

Waterloo, Ind.—F. E. Seagraves is the promoter of the Toledo & Western electric line, which is being surveyed through this place.

POWER PLANTS.

Anniston, Ala.—The Coosa Water Power Development Company, capitalized at $250,000, has purchased the land and water right in Calhoun County at Lock 3, and proposes to harness the abandoned portion of the Coosa River there and utilize it as power. The right to build a dam has been granted by the Secretary of War and the company will build the dam this summer. The company proposes to erect a power plant and lay off a number of manufacing sites.

Fremont, Neb.—The Fremont Power & Canal Company will develop a 3,500 hp. plant on the Platte River, and will furnish electric power for Omaha, Lincoln, Council Bluffs, Columbus and this city.

BIDS WANTED.

Washington, D. C.—The Treasury Department is inviting sealed proposals until March 28 for manufanturing and placing in position in complete working order in the United States Custom House at San Francisco, Cal., combination gas and electric light fixtures. Drawings, specifications and blank forms of proposal can be obtained upon application to the Secretary of the Treasury, this city.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅜@12½c.; Lake 12½@12⅝c.; casting, 12¼@12⅜c.

The St. Paul (Minn.) Electric Company has increased its capital stock to $100,000.

It is admitted that a new issue of General Electric stock has been discussed by the officials.

The Otis Elevator Company will hold its annual meeting in Jersey City Monday, March 21.

It is said that the plans for reorganizing the Eastern Ohio Traction Company are well under way.

The official announcement is made that the Bell Telephone Company of Montreal will soon issue $2,000,000 of new stock.

R. R. Govin, who represents Eastern interests in the Chicago Union Traction Company, has resigned as receiver of the company.

Plans have been made public by which the Brooklyn and Williamsburg bridges in this city will be connected by an elevated road.

The Keystone Telephone Company of Philadelphia hereafter will not issue monthly statements of earnings; the income account will be made public quarterly.

Reorganization of the Chicago Union Traction Company is about to be undertaken by majority interests, largely represented in New York and Philadelphia.

The Richmond (N. Y.) Light & Railroad Company reports for the quarter ended December 31, a surplus after fixed charges of $2,636, a decrease of $1,735.

The South Side Elevated Railroad Company of Chicago has declared the regular quarterly dividend of 1 per cent., payable March 31. Books close March 21 and reopen April 1.

The annual report of the National Carbon Company for the year ending January 31, 1904, showed net earnings of $736,441, compared with $594,372 the previous year. The increase was $142,069, or about 24 per cent.

It is reported that part of the funds derived from the million dollar mortgage authorized by the stockholders of the Philadelphia & West Chester Traction Company will ultimately be used for the purpose of double-tracking the road.

The Underground Electric Railway Company has awarded to the British Thomson-Houston Company, Ltd., of London, the contract for $7,000,000 worth of motor equipment for cars to be used on the underground and surface systems of London.

The Edison Electric Illuminating Company of Savannah, Ga., has called for redemption on or before April 1, of $500,000 mortgage bonds dated April 1, 1899, at par and 5 per cent. premium. The bonds will be redeemed at the American Loan & Trust Company, Boston.

It is said that the Metropolitan Street Railway Company of New York will not seek the credit of the city in the financing of its proposed subway. The estimated cost of construction of the new underground route is $40,000,000 as compared with $35,000,000 for the so-called Belmont subway.

The continued rise in price of the Fairhaven and Westville trolley road stock of New Haven, Conn., has brought out the fact that a determined bid is being made for control of the property by the Consolidated road. The trolley road occupies all of the street railroad field in New Haven, West Haven, East Haven, Cheshire, Branford and Milford, and is one of the best paying properties in Connecticut.

ELECTRICITY.

VOL. XXVI. NEW YORK, MARCH 9, 1904. NO. 10.

ELECTRICITY

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.......................... 3.00
Single Copies..........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

Another Decision in favor of Weston Patents

In the issue of ELECTRICITY of December 10, 1902, referring to a decision of Judge Coxe, in the United States Circuit Court for the Southern District of New York, in favor of the Weston Electrical Instrument Company versus the Keystone Electrical Instrument Company for infringement, we warned not only dealers but users of electrical measuring instruments as well to make sure before handling a given make of instruments that they were not laying themselves open to trouble and annoyance through lawsuits.

We refer to this matter at this time because Judge Wheeler of the same court has just rendered decision in another suit brought by the Weston Electrical Instrument Company of Newark against the Jewell Electrical Company of Chicago and others, upholding the validity of the patent granted to Mr. Edward Weston for instruments for measuring electrical quantities on direct current circuits. The inventions covered by the patent in question have created the practical art of electrical measurements and have unquestionably been of incalculable value to electrical engineers, scientists and all users of electricity throughout the civilized world. Moreover, these inventions of Mr. Weston's have contributed very largely to the immense advance in the industrial applications of electricity that have been made in the last fifteen years, not only in the United States but in every European country as well.

The Weston Electrical Instrument Company proposes to guard its rights and interest, and with that object in view a number of similar suits are pending against various concerns and individuals.

A New Block Signaling System.

Inventors are apparently at work in all parts of the country devising systems for preventing railway accidents. We have from time to time referred to some of these in ELECTRICITY, and we now propose to describe another, recently brought out by a resident of Warwick, R. I.

This system is intended for use in interurban trolley railways.

The signals are actuated automatically by passing cars to indicate the presence or absence of other cars in the blocks.

The signaling system is particularly adapted for use on a single-track road with turnouts, each section of single track constituting what is known as a block. Each end of each section is provided with a signaling apparatus, both of which are moved at the same time to set the signals when a car enters an empty block and to restore the signals to normal conditions when the last car leaves the block. When a car enters the trolley wheel comes in contact with and operates a switch lever, which is thrown to the contact button by the passing trolley and through the wire acts on the signal to energize a magnet and cause a mercury switch bar to rise and break the electric connection, de-energizing another magnet, and allowing the target to fall to the danger position. As this target falls it also allows the switch bar to fall and connect the mercury wells, causing the current to pass through the line and light the cautionary signal, which is an incandescent lamp showing a green light either day or night at the entering end of the block, thus notifying the entering car that the danger signal at the opposite end of the block has been set. The customary signal can only be set when the danger signal at the opposite end of the block is in its proper position. When more

then one car enters the block from the same direction the magnet is energized and through the mechanism described turns back a finger a step each time a car enters the block after the signals have been set, and this finger is returned again a step toward its normal position each time a car leaves the block, until but a single car remains on the block. When the last car passes out of the block and the switch lever is thrown to the contact point a magnet is energized through the conducting wire and through the mechanism described causes the switchbar to descend and make a connection through the mercury cups thus energizing another magnet, raising the target out of the danger position, clearing the signals, and at the same time disconnecting the mercury switch, breaking the circuit and extinguishing the light of the cautionary signal.

The train in entering the block from the opposite direction operates on the signals the same as those approaching from the other direction. The lever being thrown over against the contact point acts on signal at the opposite end of the block, energizing a magnet and through the machanism throws out of contact the mercury switch, de-energizing a magnet and allowing the target to fall to the danger position. The target in falling to this position allows the mercury switch cup to make a contact and light the cautionary signal. The train in leaving this block throws the lever to the contact point, which through a wire energizes a magnet and through the magnet-operated mechanism makes the contact through the switch, energizing a magnet to raise the target and clear the danger signal. At the same time it disconnects the switch and extinguishes the cautionary signal at the opposite end of the block.

The current by which the signal mechanism is operated is taken from the trolley wire. After the current has passed through its circuit and performed its work it is conducted through wire to the ground, and where it passes through the lamps it is arranged to pass out through a resistance coil to the ground.

In the operation of the system as described the signal at the distant end of the block is set first and the signal at the entering end is set only after the signal at the distant end is in position. The signal at the entering end thus affords an indication that the system is in order and that the signal at the distant end has been set to prevent the entrance of a car to the block from the opposite direction.

If the wiring should break or the apparatus get out of order the danger signal will be set automatically. Should this danger-indicating target for any reason fail to fall to the danger position, then the cautionary signal at the entering end of the block will not be set. When the cautionary signal is not set it indicates to an approaching car that the signaling device is out of order or that there is danger ahead.

* * *

World's Production of Coal.

"Carrying coals to Newcastle" is no longer the piece of folly it once was deemed. Several years have now elapsed since a prominent American coal company delivered its first ton of coal at that famous English mart, and every year since then has added to the supremacy of the United States as the first coal producing country of the world. Great Britain, so long the chief coal source of the world, now takes second place in the roster of nations. In 1902, the United States exceeded its former rival by no less than 47,000,000 short tons. Even if the production of Canada, India, New South Wales, and all her other dependencies is added to that of Great Britain, the United States is still 20,715,451 short tons, or nearly 8 per cent. in the lead. It is now producing a little more than one-third of the entire coal supply of the world, or 301,582,348 short tons, and Great Britain's production amounted to 254,346,447 short tons, Germany's to 165,826,496 short tons. The other nations of the world brought the total production up to 884,795,343 short tons. No one, however, had any considerable production as compared with the three leaders, the United States, Great Britain and Germany.

The report of Mr. Edward W. Parker of the Geological Survey on the production of coal in 1902, which is now in press, contains a statement of the production of each country for each year for which the figures are obtainable since 1868. At the beginning of that period the United States held third place among the coal-producing countries, with an output but little more than one-fourth that of Great Britain, and 15 per cent. less than that of Germany. Twelve years later, in 1880, the production of the United States had increased until it amounted to nearly one-half that of Great Britain, and exceeded that of Germany by nearly 20 per cent. At the close of the next decade the production of the United States had increased to such an extent that Great Britain's output was only 1.4 times as much as ours, which was, in turn, about 60 per cent. more than Germany's. In 1899 the production of coal in the United States exceeded that of Great Britain for the first time in our history, the tonnage for the two being respectively, 253,741,192 short tons and 246,506,155 short tons. Each year since then the United States has increased her lead over Great Britain, until in 1902 our production exceeded that of Great Britain by more than 20 per cent. and that of Germany by more than 80 per cent. In the 35 years from 1868 to 1902, inclusive, the United States' production has increased 852 per cent., while that of Great Britain has increased 120 per cent.

The foregoing figures are interesting especially to large users of coal, such as managers of electric light and other power plants.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Navy Department continues to receive encouraging reports of wireless telegraphic achievements at sea. The other day the Minneapolis at Guantanamo made connections with the Yankee, eighty miles away.

The most powerful automobile in the world has just been turned out in France for M. Bellemy, of Paris. It is equipped with an engine of 165 hp., and is geared to a regular speed of 80 miles an hour.

Rhode Island's House of Representatives indefinitely postponed a bill requiring the licensing of stationary engineers.

Mr. George H. Winstanley gave an interesting address before the members of the Manchester (Eng.) Geological and Mining Society recently, in which, says the *Electrical Engineer*, London, he spoke in favor of electricity as being an ideal form of energy for mining purposes. He concluded that the application of electricity on proper lines was no more dangerous than the application of energy in any other form. As a rule the plant was not so costly as compressed air, and the cables were much more convenient to install than air-pipes.

A dispatch from Vienna says the statement is made that Rockefeller's agents are trying to buy up the "Saxon Edelstollen Society" in Joachimthal, which controls the entire radium output of Austria according to an old contract. This contract is now immensely valuable and American financiers, it is claimed, have long been after it.

It is understood that the taking of stock by the General Electric Company has been completed, and the annual report of

the company is now being prepared. It will probably be ready for distribution within two or three weeks.

Electricity as an agency for thawing out frozen water mains is to be tried by the authorities of Hempstead, N. Y.

Announcement was made on Saturday that the Allis-Chalmers Company has entered into an arrangement with the Bullock Electric Manufacturing Company whereby the business of the latter will be taken over and the business of both companies carried on as that of a single interest. The business of the Bullock Company will be conducted, as heretofore, by its present management, under the form of a new Bullock Electric Manufacturing Company, organized under the laws of the State of Ohio, with George Bullock as president and Joseph S. Neave as vice-president. This combination will give the Allis-Chalmers Company the facilities of an electric plant.

Members of the plan and scope committee of the Rapid Transit Commission of this city have announced that it has been decided to hold a public hearing on March 10 on the proposition of the Metropolitan and Belmont interests to build subway extensions on the east and west sides.

In a two-and-a-half-mile race between a Missouri Pacific express train and an electric car on the Leavenworth-Kansas City Line last Thursday night the railroad locomotive was beaten by two car lengths. The roads are parallel and the electric line manager waited with a party of road officials at the beginning of the stretch. The railway engineer put on all steam, and the cars ran even until the last quarter of a mile, when the electric car slowly forged ahead and bounded across the finish line at fifty miles an hour, winner by 120 feet.

A meeting of the executive committee of the New York State Street Railway Association was recently held in Utica for the preparation of the programme for the next annual convention which will be held in that city on September 13 and 14. On the second day of the convention there is to be a question box in charge of W. W. Probasco. Special attention will be paid at the next convention to the exhibits by the supply men. The number of papers on the programme will be lessened this year, as past experience has shown that with a good many papers it is impossible to get through the programme on time.

THAWING OUT FROZEN WATER PIPES ELECTRICALLY.

BY WALTER M. PETTY.

The extreme severity of this winter has caused more frozen water pipes than were ever known before, and in the suburban cities a great amount of inconvenience and even suffering has been caused by this state of affairs. The plumbers seem unable to cope with the problem, orders coming in faster than they can be filled, by the cumbersome methods of excavating the streets and heating up the pipes by steam and fires.

View of Portable Thawing Apparatus.

In some instances the frost has been found in the ground at a depth of 5 feet. In the neighborhood of New York this is considered as extraordinary. As few service pipes are buried at a depth of more than 4 feet there is small wonder at the great number frozen up.

The plumbers being unable to solve the problem of relieving the suffering householder it seems but natural that electricity, the great "cure all," should step into the breach and once more prove its usefulness to mankind.

To Mr. Walter P. Schwabe, superintendent of the Gas & Electric Company of Bergen County, at Rutherford, N. J., should be given the credit of first employing on an extensive scale the heating effect of the current for the purpose of thawing out these frozen pipes. He employs two 10 kw. transformers connected in multiple, and stepping down from about 2,400 volts to about 50 volts. A water rheostat is used to control the primary current and an ammeter is also in the primary circuit. The whole outfit is mounted on a delivery wagon drawn by one horse, and three men are employed doing the necessary work. All the wires being overhead, it is a simple matter to connect the primaries of the transformers to the commercial lines by sending a man up the nearest pole. Heavy leads of No. 0 cable are then attached, one to the service pipe requiring thawing and the other to the service in a neighboring cellar. The circuit through the primary is then closed by means of the water rheostat, and in about one minute a perceptible heating is noticed in the pipes. This increases until the water flows. Ten minutes is about the average time required to bring the water. Sometimes it flows in about three minutes and at others it requires as many as twenty.

The average length of services may be taken as about 50 feet. Bridge measurements show a resistance between houses of .15 ohms. This is for lead pipe, of which a large majority are composed. Whenever an iron service is encountered

the effect of the increased impedence is felt. The rusty joints undoubtedly add to this resistance.

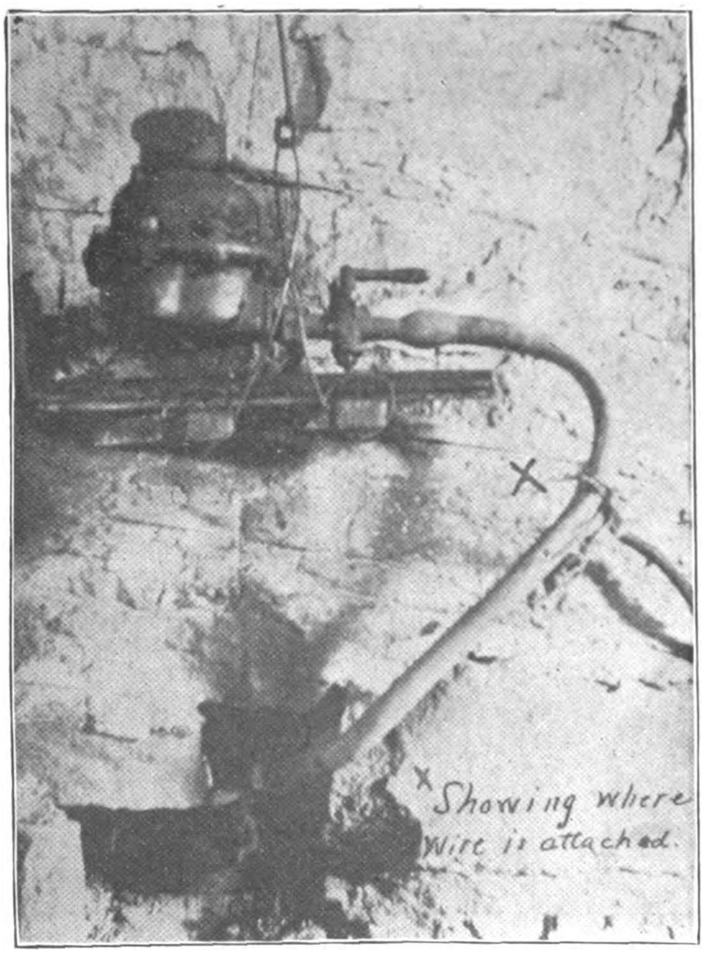
The average current in the primary circuit has been 9½ amperes, corresponding to about 360 in the secondary. In the case of iron services 5½ amperes in the primary have caused the water to flow, but the time necessary is increased. In round figures it may be said it requires about 20 kw. to do an average job.

Whenever two houses in the immediate neighborhood require thawing they can both be done at the same time.

One gang of men has done as many as 28 houses in one day, the average charge being about $8 per house, and the cost of the outfit not being more than $8 per day, this business is certainly a good paying one for the electrical supply companies.

One of the peculiar facts noted by the writer was that whenever it took longer than usual to thaw out a pipe, the first flow of water brings with it a quantity of sand and sediment which must act as a plug.

In taking bridge measurements in order to ascertain the resistances, the writer found at times he was unable to get a balance. Upon testing with a low reading voltmeter it was found that there existed a difference of potential of two-fifteenths of a volt between adjacent houses. There being no trolley line in the neighborhood it cannot be caused by leakage from the trolley circuits. Possibly the fact that the street mains are of iron and the services of lead may account for this flow of current. Time did not permit more extended observations, but they will be made in the near future.



Pipe Being Thawed Out.

LIGHTNING PROTECTION.

BY RALPH SCOTT.

Wherever the wires of any electric circuit are exposed to the weather, or what is more definite, where there is a possibility of a lightning discharge passing over them, the necessity arises of providing some means hy which such a discharge may be safely conducted to the ground.

Before taking up such means, it will not be out of place to consider a few of the principles involved. A discharge of lightning follows the same general laws as the current from an alternator, although there are several conditions which have greater import in static electricity than the simple alternating current.

Suppose we coil a wire to the shape shown in Fig. 1. If now we pass a steady current through this coil, there will be but very little self-induction. If there is passed through it an alternating current of say 120 alternations per second, the effect of self-induction will be very much greater. Practically, however, the effect even in this latter case will be very slight, and need not be considered. Of course, this self-induction (or opposition to any change in current strength) is greater in the coiled wire than in a straight wire.

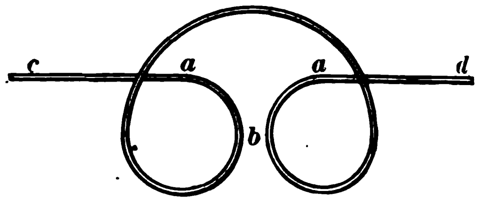


FIG. 1.

Suppose, now, a discharge of lightning pass from c to d. The self-induction of this coil will then be enormous. The reason for this is the fact that a discharge of lightning is not a rush of current in one direction only, but a succession of oscillatory discharges which pass back and forth perhaps thousands of times in the short duration of a spark which is but the ten-thousandth part of a second. As the self-induction which we have in this case would have but little effect upon a current which changes in value very slowly, yet in a current which changes likes a lightning discharge, the effect increases enormously, since the self-induction, other things being constant, is directly proportional to the frequency of the current. In passing from c to d, therefore, the discharge will create a high difference of potential between the points a and a and would doubtless jump across the air-gap at b, rather than pass around the rest of the loop.

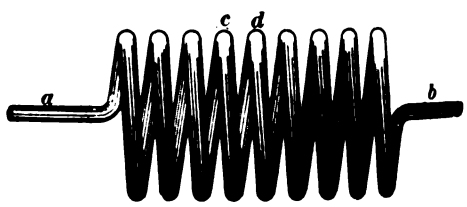

FIG. 2.

If we consider the solenoid, shown in Fig. 2, it is evident that the discharge would jump across the air-gap separating the respective turns, as from c to d, rather than pass through the coil. It is in this manner that street railway feeders are usually coiled when they pass the bus bars of the switch or distributing board to prevent the possibility of a discharge passing through the generators.

In the spark coil, shown in Fig. 3, which has an iron core, it would be impossible for a lightning discharge to circulate around the coil, but it would jump from one of the terminals AB of the coil

to the other; this action protecting the coil itself from injury, but introducing a fire hazard. If a wire connected to the ground was to be placed between these terminals, the lightning would escape to ground without dangerous consequences.

The above shows the protection from lightning which is assured to any highly inductive circuit if means are provided to allow the discharge thus impeded to escape to the ground.

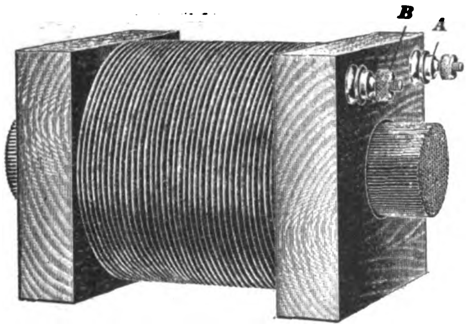

FIG. 3.

Lightning itself may be said to possess but few destructive tendencies from a thermal point of view. It is seldom that it alone causes the destruction of any inductive device. In the case of a non-inductive fine wire, the wire will be burned up, but it is of rare occurrence where a wire of a number greater than 20 is thus destroyed. When, however, the discharge jumps from one conductor to another, across which a difference of potential is maintained by some electric source, the arc forms a low resistance path across these points, across which the dynamo or other current passes. When such a current starts, if the distance be not too great, it is usually very nearly a short circuit, the heavy current thus passing acting destructively. Take, for instance, the armature of a

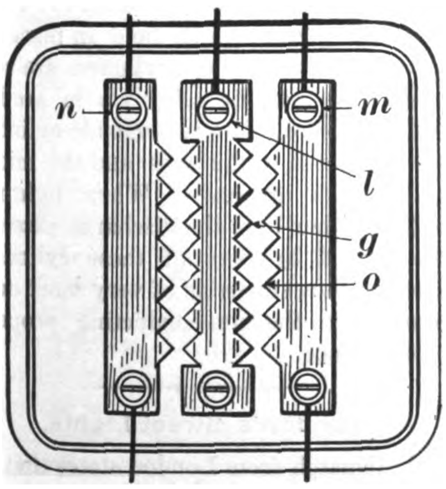

FIG. 4.

dynamo. When lightning passes through this armature, the discharge possibly leaps from two or more points in the armature conductors to the core, after which the inertia of the revolving parts completes the destruction by continuing the short circuit.

Before taking up the subject of the protection of generating or translating devices, the protection of telephones, signals, and telegraph instruments will be considered.

It is a well-known principle that lightning will more readily escape from a point, to a plate, or other points, than from a plate to a plate. This is due to a convection or silent discharge that takes place, and also because a greater amount of material is converted into a conducting gas when the discharge leaps from a point, owing to the minimum cooling material which exists at this point. This renders a much lower resistance path than would otherwise be the case.

In Fig. 4 is shown a simple form of saw-tooth arrester which utilizes this principle. Three metal strips or plates are provided as shown, having points g, o,

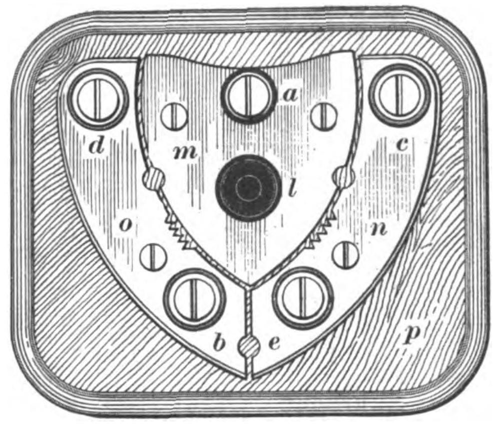

FIG. 5.

etc., resembling saw teeth. The central plate is connected to ground by the binding post l. The other two plates are in series with the line wires which are connected to the binding posts m and n. When the lightning discharge comes over either wire, it passes from the point to ground instead of going through the instrument. This type of arrester answers admirably for conducting a charge (induced in a line by proximity with a heavily charged cloud) silently to ground. As the sparks leap from one point on the line side to another on the ground plate, the ground thus established is not maintained because the difference of potential used is not sufficient to keep up the arc after the lightning spark has ceased.

In Fig. 5 is shown a type of lightning arrester which has been applied to both telephone and telegraph circuits quite extensively. Upon a wooden base, p, the metal plates, o, m, and n are secured.

Binding posts, d and c are connected to the line wires, while a is connected to ground. The instrument to be protected is connected to the binding posts, b and e. The discharge either leaps from the points to the plate m or jumps across the intervening space. A plug, l, may be inserted in the aperture shown so that it will connect either plate to ground to the lines in series. In practice this arrangement has proved itself both economical and efficient.

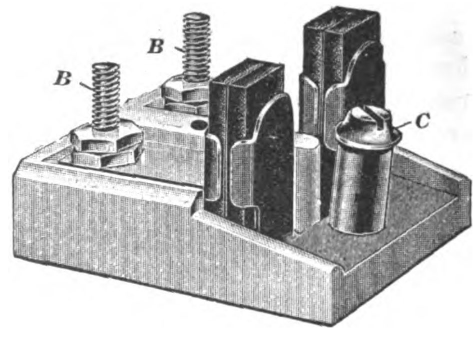

FIG. 6.

Another extensively used arrester is that illustrated in Fig 6. Upon a suitable porcelain base are mounted the binding screws B, these being connected to the lines. These binding screws are also connected by flexible means to small carbon blocks which are separated from other similar blocks connected to ground at c by means of paper or mica strips. A discharge will readily puncture this insulation and escape to ground, leaving the instrument uninjured.

In Fig. 7 is shown a standard form of combination arrester and sneak current protector. The line wires are connected to the screws, B—a small fuse carried on a holder and forced into contact with brass clips, which latter are connected to the lines and to the carbon blocks respec-

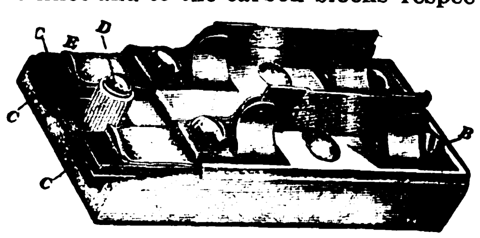

FIG. 7.

tively. The blocks, c, are insulated by mica, as stated before, and are held in place between the ground plate and the springy clips, E.

A special form of arrester which is applied to railroad signal circuits is shown in Fig. 8. Upon a porcelain form, F, the coil, H, is wound, consisting of a number of turns of bare iron wire. Above this coil is a brass strip, G, which is connected by the binding post, B, to ground. A is connected to the line wire, and D to the relay. Between C and D is a fuse. Lightning coming to A will jump to G

before it has circulated around many turns of H. Sometimes as many as 30 such arresters are arranged side by side. At E

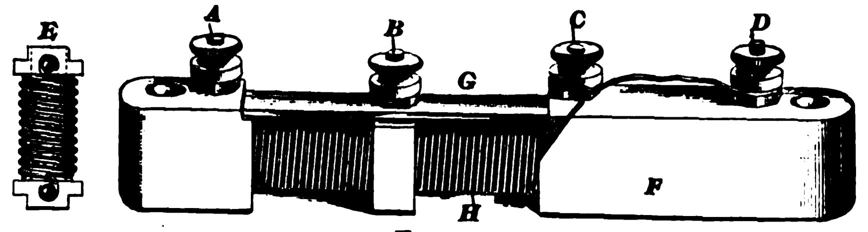

Fig. 8.

s shown a reduced drawing of another form of signal arrester. These are arranged in banks as shown in the illustration.

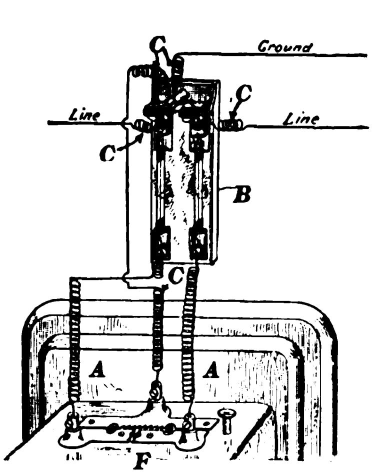

Fig. 9.

In connecting up lightning arresters, great care should be taken that no solenoids, kinks or bends occur in the ground wire, although the usual practice is to

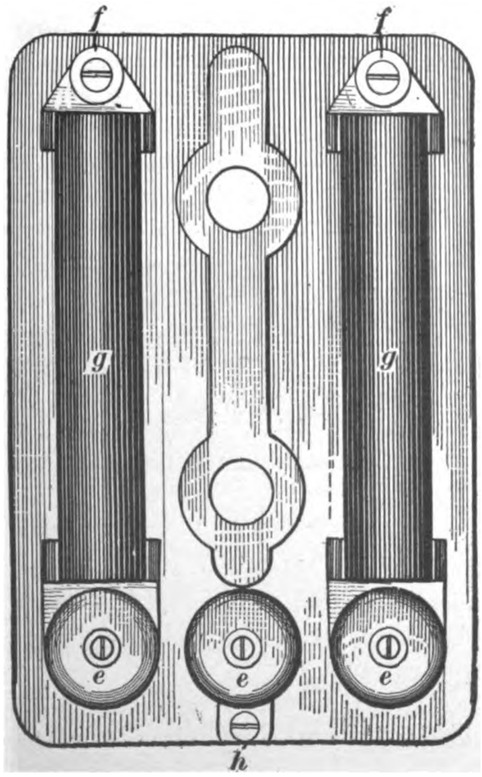

Fig. 10.

form the ground wire into fancy coils after it leaves the arrester. This is a poor scheme, since it tends to bring about a dangerous condition.

In Fig. 9, which represents a common way of connecting a telephone to the lines, the coils, C, should not be permitted, as this arrangement causes the lightning to seek another path rather than that direct to ground. On the other hand, the coils, A, insure greater protection for the instrument since they impede any charge which tends to pass through the instrument rather than pass directly to ground.

In Fig. 10 a form of arrester which is applied to high tension alternating circuits is shown. Upon a porcelain base, the non-inductive, non-metallic rods g are

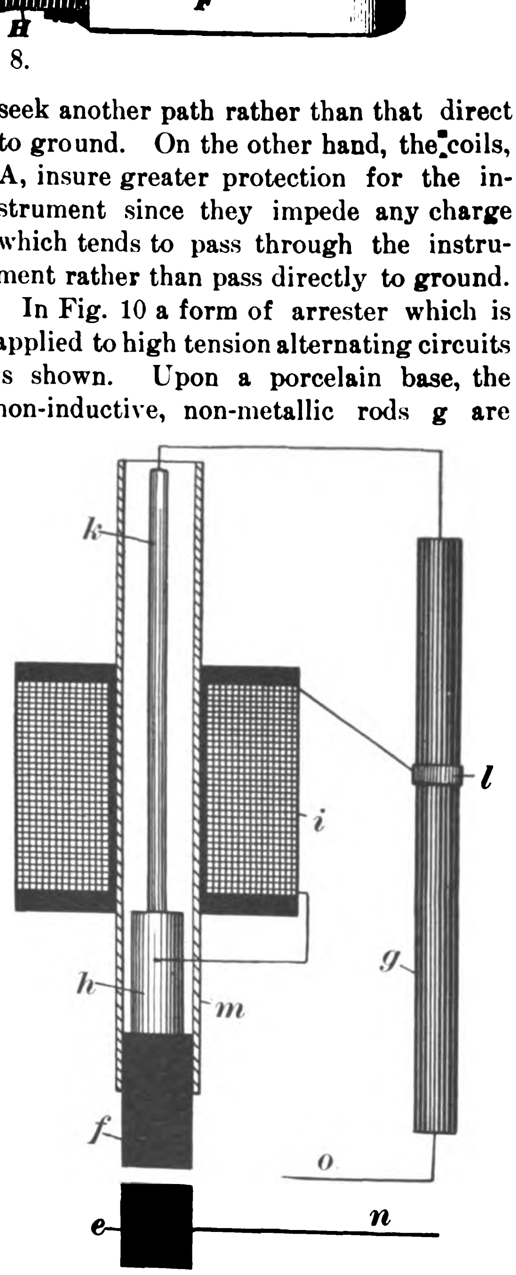

Fig. 11.

mounted. These have a high specific resistance; so high, indeed, that, when the full difference of potential of the circuit is across these resistances, they allow but a small current to flow. This does not effect the lightning discharge, however, as, being in the form of rods, they are practically non-inductive. Connected to these are two metal cylinders e e. The central cylinder is connected to ground by the connector h. The line wires are connected to f. If a discharge jumps from one of the outside cylinders to the grounded cylinder, a current from the line (if the circuit is grounded) escapes also. But this current is so small that upon the cessation of the discharge it ceases.

In Fig. 11 is given a diagram representing the connections and principles of the Garton arrester. Wire o is connected to the line, generally a railway feeder. The graphite rod g has a contact ring l to which one end of the coil i is connected. The current is wound on a non-metallic tube m within which is a freely sliding iron core h. To the latter are fastened

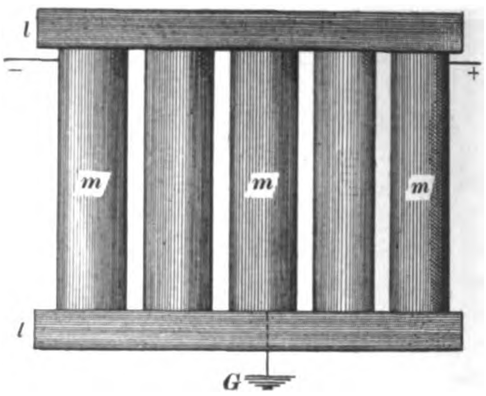

Fig. 12.

carbon pieces f, which carry the arc, and also the rod k. The carbon piece e is connected to ground by the wire n. When a discharge comes along o, it will pass through g, k, and f, across the air-gap to ground. Since this is a grounded railway circuit, the current follows the arc, the coil being shunted by part of the resistance, the current passes through it, thus lifting up h, which action combined with field set up by i disrupts the arc. When the arc is broken the carbon f returns to its normal position. It is noticed that in this arrangement the lightning does not pass through the coil i. This is necessary since i has a large amount of self-induction.

The principle of one form of Westinghouse arrester is shown in Fig. 12; l l are porcelain pieces which hold in place the cylinders m m. These cylinders are composed of a metallic alloy whose arc is a non-conductor. The two outside cylinders are connected to the lines and the middle cylinder to ground. When lightning strikes either line, the discharge passes to the ground by way of these cylinders. The arc thus started is of very short duration, due to the non-conducting property of the vapor.

London's Street Lights.

A dispatch from London states that the most recent returns show that the streets of the 118½ square miles of that city are lighted by 4,974 electric arc lights, 1,185 electric incandescent lights, 56,690 incandescent gas lamps and 18,248 flat flame gas burners.

DASH POTS FOR CORLISS ENGINES.

ARTICLE II.

BY W. H. WAKEMAN.

As a heavy dead weight dash pot is decidedly objectionable, it becomes necessary to devise one that will be light when it is time to start it into action, and heavy when weight is required to close the valve quickly. This seems almost like an impossible feat when first considered, yet it is accomplished with great precision in the modern dash pot, one of which is illustrated in Fig. 3. I do not mean to say that the weight of iron is transferred back and forth, to give the above mentioned result, but by an ingenious application of natural laws the desired result is secured.

The upper part of this dash pot 2 is

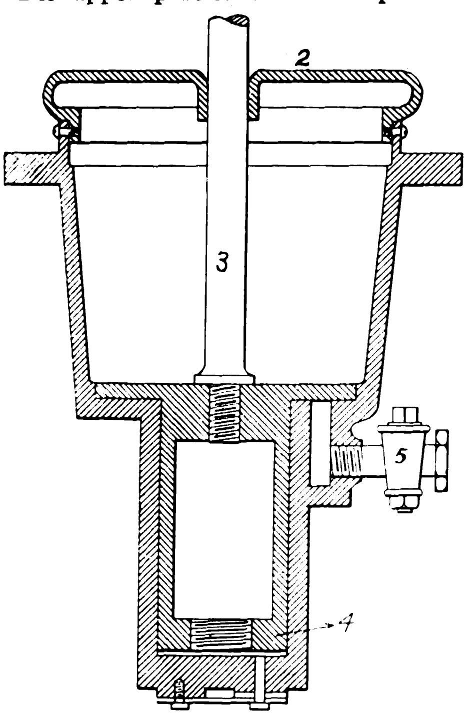

FIG. 3.

stationary as it forms a guide for the rod 3 which is fastened into the hollow plunger 4. The object in making this hollow is to have it as light as possible. When this plunger is raised by the valve gear above, air rushes in through the plug cock 5 and fills the large space below the upper part of plunger. When the valve is released this part of the dash pot offers practically no resistance to the descent because it is in equilibrium, but as it nears its present position, air is trapped underneath it, forming a cushion which prevents pounding. In order to prevent excessive cushioning, some air is allowed to pass out through the plug cock 5 which is adjusted to give the right amount.

It will be noted that there is a small chamber under the hollow plunger 4. When the plunger is raised this chamber is enlarged, and, as there is no way for admitting air into it, a partial vacuum is formed here.

Inasmuch as some men in charge of plants have mistaken ideas on the subject of a vacuum, and others appear to have not given the matter attention, a few remarks along this line are in order. A complete vacuum is a space from which everything has been removed. While this may seem to be a simple matter, it is more complicated than it appears. For illustration take the dash pot under consideration. The small chamber under the hollow plunger contains air, and as the plunger is raised this air expands until the whole chamber is filled with it, although it may be made twenty times as large as it now is. When this plunger is at its highest point, the chamber is still full of air, just as full as it is now, but the pressure is reduced according to the increase in volume. It is understood that no more air is admitted.

When the air pressure is reduced in this way, a partial vacuum is said to exist in the space below the plunger, therefore it is called a vacuum chamber.

The production of a partial vacuum does not create power or pressure, but it removes resistance, therefore it allows the pressure already existing to perform work or produce power. Let us note the possible result in this case. As the plunger stands in the cut, air pressure is equal all over it. When it rises, the pressure under it is reduced. Suppose that the air pressure on top of it is 14 pounds to the square inch, and when at its highest point the air pressure under it is reduced to 4 pounds. The mean effective pressure acting on the top of it to force it downward is 10 pounds per square inch.

If the plunger is 4 inches in diameter, its area is 12.5 square inches, therefore the total pressure forcing it downward is $12.5 \times 10 = 125$ pounds. To this may be added the weight of plunger and rod, from which must be subtracted the friction. If we assume that weight balances friction in this case, then the total effective force is 125 pounds, so that the reason for its rapid descent is plain.

Attention is called to the fact that the rod is rigidly attached to the plunger, with a guide above it. As the valve crank swings through part of a circle, there must be a joint somewhere in this rod above our point of view.

Fig. 4 illustrates another kind of dash pot, differing in detail from the previous illustration. The rod is attached to a solid plunger, which is now in its highest position. Air is prevented from entering the vacuum chamber 2 by packing rings 3 which are similar to those used in some steam pistons. Air pressure acts on the top of this plunger to force it downward, but is not effective over the whole surface because pressure exists in the cushion chamber 4 and it is supposed to equal the outside pressure as it enters freely.

After the descending plunger has passed the point 5 the remaining air is trapped under the upper part of plunger, except what escapes through the valve 6. Suppose that the sudden descent of this plunger raises pressure in the air chamber 4 to 30 pounds, while the pressure acting on the upper surface is 14 pounds, making the mean effective pressure $30 - 14 = 16$ pounds per square inch.

Assuming the diameter of small part of plunger to be 4 inches, its area is 12.5 square inches. If the diameter of large, or upper part, is 8 inches, its area is 50 square inches. The surface on which 30 pounds acts is $50 - 12.5 = 37.5$ square inches. Then $37.5 \times 30 = 1{,}125$ pounds acting to arrest the plunger.

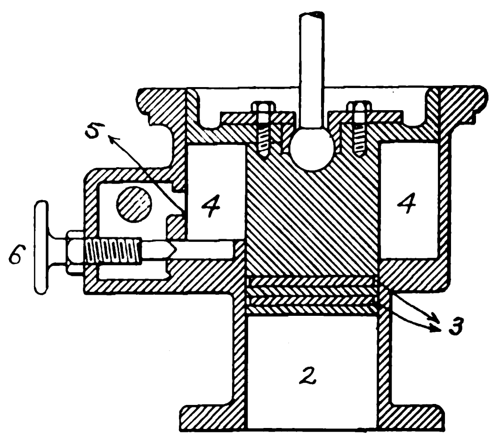

FIG. 4.

In reality it is more than this because pressure increases in the vacuum chamber 2 and this assists in stopping the plunger. It will be noted, however, that this action lasts but an instant.

A careful consideration of this chapter will show the reader that when the dash pot plunger of a modern Corliss engine is started from a state of rest it is comparatively light, but when the time arrives for it to close the steam valve, it is to all practical purposes much heavier.

In this case the rod is attached to the plunger by means of a ball and socket joint which permits the rod to swing in any direction. It also permits the plunger to turn in its cylinder.

When wear due to long service causes lost motion at this point, it may be taken out by loosening the cap screws shown at either side of the ball joint, and moving the plates nearer together.

ELECTRICAL STATION PRACTICE.

ARTICLE XXVII.

BY W. H. RADCLIFFE.

An important modification of the dynamotor, discussed in the latter part of the preceding article, is the rotary converter. This machine forms as it were a link between alternating and direct current systems, being in general a combination of an alternating current motor and a direct current generator. Although of comparatively recent adoption, it has already gained such a foothold in certain classes of distribution from central stations that it has practically become a fixture in all large electric railway systems and in other installations where heavy direct currents of constant potential are required at a considerable distance from the generating plant. In such cases a rotary converter is installed in the sub-station and being simpler in construction, higher in efficiency, more economical of floor space, and lower in price than a motor-generator, set consisting of an alternating current motor and a direct current generator which might be used in its place, it has almost entirely superseded the latter machine for the class of work mentioned.

There are two types of rotary converters, one of which has its field poles excited by a current which is induced in the field winding, while the other has its field poles excited by passing a direct current through the field winding. Owing to the great sensitiveness of the induction type of rotary converter to the conditions of the circuit in which it is connected, its operation is rendered more or less difficult under ordinary circumstances, so that the direct current type is almost universally employed for commercial purposes. The direct current rotary converter will, therefore, be the only one to which we will devote our attention. In order to understand the principles of this machine it is necessary to bear in mind that in every dynamo an alternating current is generated, which in an alternator is drawn from the armature winding without change by means of collector rings, and in a direct current generator is drawn from the armature winding by means of a commutator which by reversing the alternations at frequent intervals produces a direct current in the connecting wires.

For the purpose of illustrating the principles upon which the operation of rotary converters in general is based, reference will be made to the four-pole, single-phase converter shown diagrammatically in Fig. 27. The two views represent opposite sides of the same field magnets, N, S, etc., and of the same armature c, at A being shown the alternating current end of the armature and at B its direct current end. At first let us consider simply the end A, disregarding for the present the connections at the opposite end B. It is seen the armature winding is connected at four equidistant points, h, f, k, and l, to two collector rings v and z; upon a closer examination it is apparent that of the four equidistant points in the armature winding those which are subject to the same magnetic conditions are connected to the same collector ring. Thus, the armature coils directly beneath the two north poles N and N are joined to the same collector ring, while those directly beneath the two south poles S and S are both joined to the other collector ring. If the magnetism in the poles be maintained as indicated in the diagram, and the armature c be rotated, a single-phase alternating electromotive force will be developed between the wires b and d. On the other hand if a single-phase alternating electromotive force be supplied to the wires b and d, and the magnetism in the poles be maintained as before, the armature after being started will continue to rotate and this part of the machine will operate as an alternating current motor.

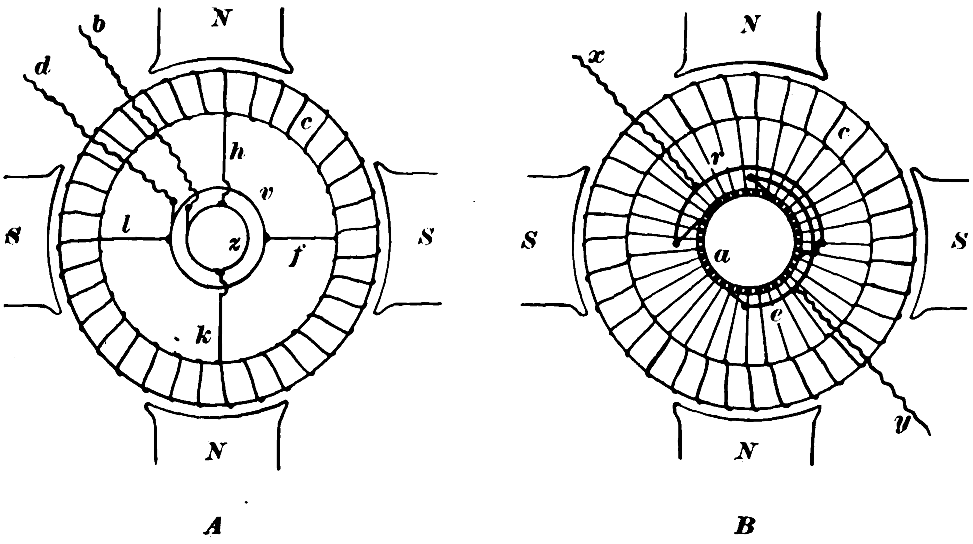

FIG. 27.

In the armature winding there is besides the alternating current fed into the machine an alternating electromotive force maintained by the rotation of the armature winding past the magnet poles. The conditions are therefore similar to those in any direct current generator, and when the armature winding is connected at the opposite end to the bars of a commutator a in the usual way, brushes pressing on the commutator a will deliver to the bus bars r and e and thence to the leads x and y a direct electromotive force which will cause a direct current to pass through any closed circuit connected to xy. The result is therefore the same as though the alternating current which is fed into the armature for causing rotation were the current actually generated in the armature, although in reality these two currents oppose each other; this fact, however, does not in the least affect the respective functions performed by each of the currents, for the machine acts as though it cared not, so long as there was alternating current in the armature winding, whether this current were that fed into it through the collector rings or that developed in it through the ordinary process of induction.

There is a serious objection, commercially, to the single-phase rotary converter which has here been chosen for illustrating the principles of converters as a whole. This objection is that common to all single-phase motors, and is the special means that must necessarily be employed for starting machines of this type from rest. This objection, however, is overcome when two-phase or three-phase connections are used in the motor, so that in practice single-phase converters are very seldom employed. Inasmuch as the general principles of operation in all converters are the same, the single-phase type was taken for illustration on account of its simplicity.

The only difference between the construction of single-phase converters and two-phase converters is that in the latter the armature winding between each pair of poles is connected in succession at four equidistant points to four collector rings so that there is in each section of the armature winding, bounded by a north and a south pole, two complete circuits terminating at the four collector rings; whereas, in a single-phase converter, there is in each similar section of the armature winding but one complete circuit terminating at two collector rings.

In three-phase converters each section of the armature winding lying between a pair of poles is connected in succession at three equidistant points to three collector rings so that there is from the motor side of this machine three complete circuits through that portion of the armature included between each north and south pole. In both two-phase and three-phase converters, the armature connections on the generator side do not differ from those shown in Fig. 27 for the single-phase converter. In many converters the field magnets are compound wound to facilitate different loads being carried without a decrease in voltage, although those employed on short distance distributing lines are shunt wound. The series coils in compound wound converters are excited, of course, by the direct current generated in the machine, while the shunt coils are excited with direct current from a separate source.

The rotary converter is a reversible machine; that is, if it is supplied with direct current of the proper voltage at its commutator end it will run as a direct current motor and deliver alternating current to the collector rings. While this feature is sometimes taken advantage of in starting the converter from rest, as will be shown later, the machine is not often used permanently in this way, its commercial application being usually the conversion of alternating currents into direct currents. When driven by direct current, however, the machine operates in every respect like a direct current motor, its speed of rotation depending upon the relation existing between the strength of the field and the direct current voltage applied. If the field be weak with respect to the magnetism resulting from the applied voltage, the armature will rotate at a high speed, increasing until the conductors on the armature cut the lines of force in the field so as to develop an electromotive force which will be equal to that applied. On the other hand, if the field be strong with respect to the magnetism resulting from the applied voltage, the armature will rotate at a low speed. If, therefore, it be desired to operate the converter in this manner and maintain an alternating current of constant frequency, the speed of rotation must be kept constant by supplying a constant voltage not only to the brushes pressing on the commutator, but also to the terminals of the field winding. When the converter is driven by alternating current it runs as a synchronous motor; that is, it operates in synchronism or in step with the alternator supplying the current, and its speed of rotation is governed by the frequency of the alternator.

The commutator of the rotary converter is its most troublesome part, for owing to the many pieces of which it is composed and the necessary lines along which it is constructed its peripheral speed must be kept within reasonable limits. The peripheral speed of the commutator in feet per minute is the circumference of the commutator measured in feet and multiplied by the number of revolutions per minute. Experience has shown that a rotary converter should not be run so as to give a peripheral speed of the commutator exceeding 3,000 feet per minute, else the centrifugal force developed will be liable to cause the commutator to fly apart. Another limitation imposed is the voltage between adjacent commutator bars, and in value this should not exceed eight or ten volts to give satisfactory results; furthermore, if the commutator bars are made narrow in order to obtain the necessary number for the desired voltage with the minimum circumference and therefore low peripheral speed, the brushes employed to collect the current are liable to require excessive width in order to provide the proper cross-section and yet not cover more than two bars at once. Assuming, therefore, that the usual practice be followed in giving the commutator bars a reasonable width, the peripheral speed of the commutator must be kept within the limit previously stated by feeding the converter with alternating current of a comparatively low frequency. For a rotary converter delivering 500-volt direct current, the proper frequency for the alternating current circuit has been found to be 25 cycles per second.

When the rotary converter is operated in the usual manner on an alternating current circuit, the direct electromotive force developed can be varied from zero to a maximum by changing the value of the alternating electromotive force supplied to the machine, or it may be altered within a limited range by moving the brushes around the commutator, or in a compound wound converter by changing the amount of compounding. Under ordinary conditions, varying the voltage developed by changing the voltage at the motor end is not practical, so it is seen from what has just been stated that the voltage developed can be varied only over a limited range. In addition to this, the voltage developed at the direct current end always bears a certain constant proportion to the alternating current voltage applied at the motor end; this is due to the same winding being used both for motor and generator purposes. In all cases the proportion is such that the alternating current voltage is the lower, being in the single-phase and in the two-phase converters about .707 of the direct current voltage, and in the three-phase converters about .612 of the direct current voltage. It is thus seen that whatever value of direct current voltage is desired the value of the applied alternating current voltage must be lower, requiring in consequence the installation of step-down transformers at the sub-station for reducing the line wire voltage to conform to the direct current pressure required.

As to efficiency, the rotary converter may be said to have approximately the same value as that in the average direct current generator of the same output, although in reality the converter is a trifle more efficient on account of affording a somewhat shorter average path for the current in the armature, reducing in consequence the resistance loss and the armature reaction. These may be still further reduced by increasing the number of connections between the armature and commutator, although, as has previously been shown, there are certain limitations in this direction on account of the number of commutator bars exceeding their practical limit. Since there is ordinarily less resistance loss in the armature of a converter than in the armature of a direct current generator of the same output, the former may be overloaded to a far greater extent than the latter. Thus, a two-phase converter may be overloaded approximately 60 per cent., and a three-phase converter may be overloaded about 30 per cent. above the respective outputs of these machines if operated as direct current generators.

Electricity in Japan.

A great deal of activity is at present being shown in Japan in the utilization of electricity for lighting, power and traction purposes. The electric light works at Tokio (the capital) are not a new installation. They have been in operation for some considerable time with a measure of success which may be gauged by the fact that it has become necessary to greatly extend the power house. The plant at present installed has a capacity of 5,050 hp., and this is being increased by an additional 3,600 hp. Electric current is being supplied from the original plant to the equivalent of 100,273 10-cp. lamps, and we understand that the demand for

light is so heavy that applications for connections are received at the rate of over 1,500 a month.

The new plant is expected to be in operation in April next, and immediately on its completion work will be commenced on a further extension, which will ultimately increase the output of the station by 10,000 hp. A part of this scheme is to be realized by the summer of next year. Fresh demands for electric power are being made upon the electric light company by the light railway company, which is operating an extensive system of light railways in the city. In other parts of Japan there is evidence of similar progress in which the municipalities are taking a prominent part. For instance, one city proposes to develop close on 10,000 hp. by utilizing the power of the Tama River. This scheme provides for the harnessing of the water at three different places and the erection of an equal number of generating stations. Other places are going in for electric traction systems, such as Osaka, where the municipal authorities are seeking Government authority to lay down electric tramways as a municipal undertaking.

Another instance of activity in the same direction is the completion of the Keihin electric railway, which is under construction. It runs between Shinagawa and Kanagawa, a distance of about 20 miles. The company is laying down a power plant with a capacity of 540 hp., which will supply current for working the line, and an average speed of 50 miles an hour is to be maintained. It is likely to prove a formidable rival to the Government railway between Yokohama and Shimbashi, as it will have the advantage of a more frequent and rapid service.—*Electrical Engineer, London.*

SOME CRITICISMS ON WORKSHOP PRACTICE.*

BY E. KILBURN SCOTT, M.I.E.E.

When in the workshops one is apt to become so accustomed to the methods in vogue that they appear to be the only methods possible. As a matter of fact, however, many of them are at least open to question.

For example, take such a simple matter as the use of a keyhole saw; like every other saw it is made to cut on the pushing stroke, and one must needs be very expert to prevent it bending and snapping off. The difficulty would disappear if the saw were turned end for end, and the cutting done on the pulling stroke in the same way as a Japanese workman does his work.

This reminds the writer that whereas in a slotting machine the cutting stroke is in the direction of the bedplate on to which the work is temporarily bolted, a shaping machine, on the other hand, has its working stroke outwards, or away from the bed frame. Surely the tool ought to cut on the home stroke, as it would then not only make a cleaner cut, but the ram would be in tension instead of compression, and could be of lighter construction. It would probably also be easier for the attendant to see when he was cutting down to the scribed mark.

For machining large diameter alternator rings it is usual to employ a horizontal face plate lathe or boring mill, and as the diameters of alternator armatures have increased very rapidly of recent years, the distance between the uprights carrying the bridge have to be a considerble distance apart. Now, if instead of rotating the armature ring, the cutting tools are rotated, then these uprights can be done away with, and all that is required is a rigid central column to carry the cross-arm tool-holder. In this way any diameter of armature could be machined.

In winding copper wire on to a field coil it is usual to place a brake on the spindle of the spool which is being unwound so as to keep the wire taut. This naturally gives a good deal of side pull to the bearings of the lathe and there is considerable friction. Now, if two spools were to be wound on the same lathe and the wires lead on to the spools from opposite directions, say, top and bottom, these side pulls would be neutralized to a large extent.

There is also room for considerable improvement in winding coils, for the present tap-tapping of the wire with wooden mallets is anything but satisfactory. What appears to be wanted is a change gear, which at each revolution of the coil would move a small pair of gripping wheels the exact distance of the diameter of the wire. A knock-off reversing motion could be arranged to start the wire back again when it reached the end of each layer.

Soldering by hand with an iron is another of those finicking things which ought to be banished from an electrical engineering works. Where possible, all joints should be mechanical, but if solder must be used it might just as well be done wholesale by first dipping the parts into flux and then into melted solder. There is no reason why, with a little special designing, the joints between armature coils and commutator segments should not be made in this way; anything would be better than the present finicking messy handwork. In some Continental workshops the short-circuiting end rings of alternate current motors are soldered to the rotor conductors by dipping in an annular ring of melted solder.

In the manufacture of mica cloth and mica paper there is far too much handwork. Surely some machine method of laying on the thin laminæ in three layers to break joint could be devised. Compared with such a mechanical miracle as the Hoe printing press, or even an ordinary loom, it should be simple. If some firm gave their cleverest improver the problem to work out with ample facilities for experimenting, I'll be bound he would find a solution in quick time.

Instead of grumbling about the low prices now prevailing manufacturers should be continually devising short ways of doing the work, or if they cannot devise, then adopt the labor-saving dodges of others. I wonder how many shops in this country can show armature coil-tapping machines in use? To my knowledge, they had been used in the States and on the Continent four years before one was even tried here. Again, consider the amount of material which the English manufacturer buys ready made, for example, stampings, mica cloth, and even machine frames, spindles, etc., finished. Surely this is only half playing the game.

Prices are likely to go even lower, and for the smaller sizes to pay, they will have to be made as Singers make sewing machines or Kynochs make small arms. I wonder which firm will be first to paint their small castings by running them on an endless chain through a paint tank.

*From the "Electrical Review," London.

Demand for Submarine Boats.

The Electric Boat Company, it is claimed, has on its books orders for submarine boats the net profits on which will represent several hundred thousand dollars. Already the British Admiralty has bought 19 boats from the company, and this number, it is stated, is to be increased to 29 boats. A number of the Continental powers have purchased one or more submarine vessels from the Electric Boat Company and the United States Government has several in commission.

Underground Cables in Baltimore Fire.

The Baltimore fire has been the unfortunate means of settling many disputed points for the engineers of this country, and it has, among other points, emphasized most forcibly, in the minds of dis-

interested observers, the superiority of underground cables for electrical transmission of power as compared with old overhead methods.

The Standard Underground Cable Company has installed during the past few years in Baltimore many miles of underground cable, in the municipal subway for the Western Union and Baltimore & Ohio Telegraph Companies, the Maryland Telephone Company, the city fire and police departments and the United Railways & Electric Company. The main conduit lines run the entire length of the burned district and the manhole covers were in many cases covered with piles of hot brick and stone to a depth of 20 feet.

In spite of the intense heat there is so far as is known not a single instance of trouble on the cables in manholes or subway except where exposed ends of cables were destroyed by the fire, and the cable system is in perfect condition to-day.

Two three-conductor cables installed for the United Railways & Electric Company over a year ago, and which terminated in the new and unburned portion of the Partt street power house, extended the entire length of the burned district, and were carrying current to the substation at 13,000 volts, the second day after the fire, without any interruption to service.

This record compared with the ruin of overhead construction which was universal certainly gives food for thought to all users of wire.

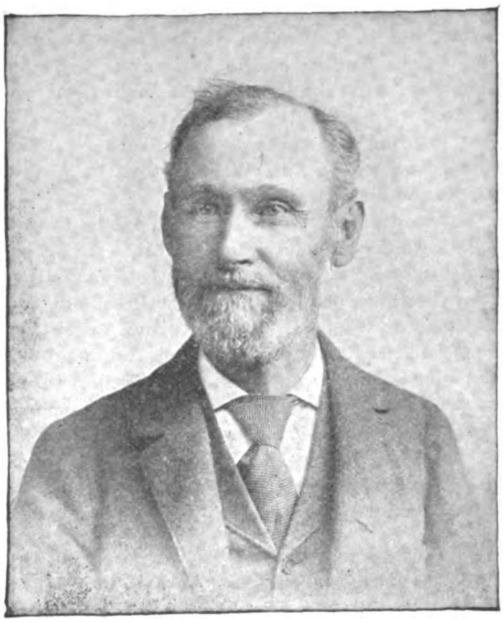
Death of Andrew Howard.

Andrew Howard, president of the Phoenix Glass Company, Monaca, Pa., died Saturday morning, February 27. He had only been ill about ten days. He was attacked with a species of grip, which developed into pneumonia. The funeral was held at his residence in Wilkinsburg on Monday.

Mr. Howard was born in 1837 in Pittsburg, and after a thorough mercantile education in the schools of that city was employed as a clerk with the transportation firm of Clark & Thaw, afterwards merged into the Star Union Line, of which Mr. Howard was made the first cashier. He resigned this position in 1880 to organize the Phoenix Glass Company for the purpose of manufacturing a patent glass insulator, which product was abandoned and the manufacture of lamp chimneys taken up. From this beginning, and through his enterprise and energy principally, has the Phoenix Glass Company grown to its present large proportions.

A man of wonderful tact, discretion and judgment, Mr. Howard was unassuming to the last degree, and beloved by everyone with whom he came in contact. His geniality and benevolence were so marked that it has been said of him, "If he has a fault it is that he is too kind." In his death the glass trade has lost an honored member, his associates and employes their best friend, and the world at large one of nature's noblemen.

Mr. Howard's popularity with the em-



ANDREW HOWARD.

ployes of the Phoenix Glass Company was evidenced by their attendance at the funeral, special trains being run from the Washington and Monaca factories. The floral offerings were expressive of the general high esteem in which the deceased was held, and came in profusion from his business associates, the Glass Manufacturers' Association and the employes.

ELECTRICAL PATENT RECORD.

LETTERS PATENT; ISSUED MARCH 1, 1904.

Electric Railways and Appliances.

753,341. Safety-Guard on Electrical Cars. Charles A. Willard, St. Louis, Mo. Filed Jan. 29, 1902.

753,387. Electric Train Order and Signaling System. John C. Gleason, Springfield, O., assignor of one-half to James B. Von Schriltz, same place. Filed July 24, 1903.

753,436. Safety Apparatus for Motor-Cars of All Kinds. Karl Schmidt, Cothen, Germany. Filed Oct. 12, 1903.

753,536. Contact-Device for Electrically-Propelled Railways. Henri Berthoud, Neuchatel, Switzerland. Filed July 10, 1902.

753,542. Trolley. Alexander O. Calderwood, Gloversville, N. Y. Filed Aug. 6, 1903.

753,552. Trolley for Electric Cars. William A. Daggett, Vineland, N. J. Filed Sept. 3, 1902.

753,554. Trolley. Arthur S. Deem, Reading, Pa. Filed Aug. 8, 1903.

753,617. Trolley-Replacer. Francis A. Nolan, St. Paul, Minn. Filed Jan. 16, 1902.

753,802. Combined Third and Traction Rail for Electric Railways and Switching Systems Embodying Same. Edmund O. Morgan, Chicago, Ill., assignor, by mesne assignments, to the Morgan Electric Machine Company. Filed Aug. 27, 1902.

753,803. Combined Third and Traction Rail for Electric Railways. Edmund C, Morgan, Chicago, Ill., assignor to the Morgan Electric Machine Company. Original application filed Aug. 27, 1902. Divided and this application filed Dec. 3, 1903.

Electrical Machinery and Apparatus.

753,243. Velocity-Meter. Georg Dettmar, Frankfort-on-the-Main, Germany, assignor to the Society of Electricitats Actien-Gesellschaft vorm W. Lahmeyer & Co., same place. Filed Sept. 12, 1902.

753,258. Electric Switch. Gerald W. Hart, Hartford, Conn., assignor to the Hart Manufacturing Company, same place. Filed Nov. 23, 1903.

753,278. Winding for Electrical Machines. Frederick J. Lindeman, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 11, 1903.

753,356. Brush-Holder. Charles O. Bulock, Milwaukee, Wis., assignor to the National Electric Company. Filed Aug. 21, 1903.

753,422. Armature-Winding. James F. McElroy, Albany, N. Y., assignor to the Consolidated Car Heating Company. Filed Nov. 11, 1902.

753,429. Electrodynamic Generator. George M. Pelton, Chagrin Falls, O. Filed Sept. 29, 1902.

753,461. Electrical Conductor and Coil. James C. Anderson, Jersey City, N. J., assignor to the Varley Duplex Magnet Company. Filed April 30, 1903.

753,533. Rheostat. John C. Barclay, New York City. Filed Sept. 9, 1903.

753,556. Electric Meter. Thomas Duncan, Lafayette, Ind. Filed Dec. 29, 1903.

753,704. Automatic Magnetic Circuit-Breaker. Frank O. Hartman, Mansfield, O. Filed April 10, 1902.

753,714. Conduit for Electrical Conductors. Hubert Krantz, New York City. Filed Sept. 9, 1903.

753,795. Electric Sparking Igniter for Explosive-Engines. William J. Hart, Mount Vernon, N. Y., assignor of one-half to Charles F. Splitdorf, New York City. Filed May 28, 1903.

Telephones and Telephone Apparatus.

753,252. Telephone Repeater. Merritt Gally, Brooklyn, N. Y. Filed March 18, 1903.

753,391. Casing for Telephones or Microphones. Paul Hardegen, Berlin, Germany. Filed Sept. 3, 1902.

753,411-753,412. Telephone Toll Apparatus. George A. Long, Hartford, Conn., assignor to the Gray Telephone Pay Station Company. Filed April 15, 1902, and Nov. 8, 1902.

753,466. Disinfecting Attachment for Telephones. Carlo Bravi-Bertini, Perth Amboy, N. J. Filed Sept. 16, 1903.

753,493. Telephone. Stephen O. Houghton, San Francisco, Cal. Filed April 3, 1903.

753,562. Jack-Field for Telephones. Lars M. Ericsson, Stockholm, Sweden, assignor to Aktiebolaget L. M. Ericsson & Co., same place. Filed June 18, 1902.

753,568. Portable or Table Telephone Instrument. Lars M. Ericsson, Stockholm, Sweden, assignor to Aktiebolaget L. M. Ericsson & Co., same place. Filed Sept. 30, 1902.

Miscellaneous.

753,240. Electric Alarm-Clock. Leslie H. Cushman, Lakewood, N. J. Filed Feb. 17, 1903.

753,284. Electrically-Propelled Vehicle. Hiram P. Maxim, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed April 4, 1903.

753,365. Electromagnetic Signal. William U. Colthar, Springfield, O., assignor to John C. Gleason and James B. Von Schriltz, same place. Filed July 24, 1903.

753,383. Process of Preparing Electrodes for Storage-Battery Cells. Oskar Frank, Detroit, Mich., assignor to Levi J. Lennox and the Michigan Storage Battery Company, same place. Filed May 2, 1903.

753,398. Cleat for Electric Wiring. Emory C. Hunt, Belle Plaine, Ia., assignor of one-half to Charles W. E. Snyder, Benton County, Ia. Filed Nov. 8, 1902.

753,399. Combination Bracket and Knob for Electric Conductors. Emory O. Hunt, Belle Plaine, Ia., assignor of one-half to Charles W. E. Snyder, Benton County, Ia. Filed Nov. 8, 1902.

753,509. Electrotherapeutic Device. Charles K. Munns, Corning, Ia. Filed Oct. 24, 1903.

758,690. Electric-Telegraph Apparatus. Agazio Falcone, Florence, Italy. Filed May 6, 1903.

753,757. Self-Winding Electric Clock. Frank T. Talcott and Benjamin F. Kerr, Ashtabula, O. Filed March 11, 1903.

753,759. Electrical Connection. Edward G. Thomas, Cambridge, Mass. Filed July 15, 1902.

753,819. Electrode. George J. Atkins, Tottenham, Eng. Filed April 8, 1903.

THE TELEPHONE WORLD.

Pushing Automatic Telephones in Massachusetts.

The opening move in a project to extend the automatic telephone system throughout Southeastern Massachusetts and Rhode Island is the incorporation of a new company known as the Automatic Telephone Equipment Company. The new corporation is nominally distinct from the companies which now maintain exchanges in New Bedford and Fall River with connections between the two, but the incorporators are to a large extent stockholders of the New Bedford and Fall River concerns, and the new company will co-operate with the old in establishing new exchanges and a long-distance service in that section of New England.

The Equipment Company, like the companies now using the automatic system, will obtain privileges from the main company in Chicago for Massachusetts and Rhode Island.

The stockholders of the new company are in a large measure holders of stock in the company which is now carrying on business. They, like the company now operating the system, will, of course, obtain the privileges of the system from the main company of Chicago.

Among the incorporators of the new company are Charles E. Hellier, Frank E. Sweetser and Charles B. Price of Boston; Benjamin E. Waters, Congressman William S. Greene of Fall River, and many other Fall River and Taunton mill men and capitalists.

The Farmers' Telephone Company at Anderson, Ind., has adopted a general signal of distress for its patrons on party lines. Following the general alarm the exchange operator will give the number of rings indicating the house from which the alarm came, so that the neighbors may go direct to the place where assistance is needed.

I. M. Griggsby of Goss, Mo., president of the Monroe Mutual Telephone Company, met about 75 farmers in Monroe City lately, and formed a mutual company that will work in exchange with the county lines. The farmers appear enthusiastic and start out with bright prospects for the future.

The Washington Telephone Company has contracted with F. H. Colson of Wesley, Me., for 200 telephones to be delivered before June 1. The company proposes to build a line to Roque Bluff, Wesley and Cathance Lake in that State.

The Selma, Ind., Co-operative Telephone Company lately held an important meeting there, and decided to purchase property for a permanent home, to buy a new switchboard and to otherwise improve its plant and service.

There is now only one telephone corporation doing business in Mount Vernon, N. Y. The Telephone, Telegraph & Cable Company of Eastern New York has been driven out of business there.

The Western Wisconsin Telephone Company of Arcadia, by Senator John C. Gaveney, president, and Emil Maurer, secretary, recently filed an amendment increasing the capital stock from $40,000 to $50,000.

Independent Telephone Companies Object to Postmaster General's Order.

The Toledo, O., Home Telephone Company, through its president, E. L. Barber, has joined the list of protesting Independent companies in a determined effort to have the recent order of Postmaster General Payne revoked. This order shuts the Independent companies out of all postoffices in the country.

A committee of three, of which Mr. Barber is one, and F. S. Dickson of Cuyahoga County, and Cyrus Huling of the Columbus Citizens' Company, are the other two, has been appointed to personally see President Roosevelt and ask his interference in the order. The committee will go to Washington in a few weeks and make the protest.

This contest between the Independents and the Postoffice Department promises to be an exciting one. Already written protests against the order have been made to the President and Postmaster General. The original order has been slightly modified, but the Independents consider it unfair and a menace to their interests. They want the order recalled. A perfect organization of all the Independent companies of the State has been formed. Congressmen have been petitioned to exert their influence to have the order revoked.

The Garfield County Telephone Company held its annual meeting at New Castle, Col., a short time ago and elected the following officers: President, William Chadwick; vice-president, E. E. Clarkson; secretary, W. D. Lockard; treasurer, J. A. McRae; general manager, J. S. Kass. The company has 120 telephones. The line will be extended to Glenwood Springs next summer. The incorporation of the company was authorized at the meeting.

In spite of numerous injunctions and other obstructions thrown in its way, the Independent Telephone Company has at last succeeded in getting a long distance connection between Binghamton and Elmira, N. Y., and in that way with a large number of other cities in this State, Pennsylvania and Ohio.

The farmers of Daleville, Ind., have failed to organize a telephone company which has been talked of for some time, and now the Delaware-Madison Telephone Company has announced that it has already purchased a part of the material for a local plant and will begin construction work as soon as the weather will permit.

The people of Alma, Mich., have been enjoying the fruits of a war between the Michigan State Telephone Company and the Union (Independent). The Bell Company has been branching out rapidly and the Union offered free 'phones to Alma and St. Louis. The Bell Company is now doing the same.

A report has been received from Princeton, Ind., that the Independent telephone service there is so much superior to the Bell that many Bell subscribers are having their telephones taken out and Independent telephones installed.

The Chicago Telephone Company for February shows a gain of 1,724 instruments, making the total number in use 104,368.

Recent communication from Papillion, Neb., states that an independent telephone company has been organized among the farmers of Plattford precinct. It is known as the Mutual Telephone Company and has 16 charter members. The following are its officers: W. D. Schaal, president; Dan Phelps, vice-president; J. H. Bundy, secretary; Z. T. Garman, treasurer. The farmers will do the construction work with the aid of an electrician. Work will be commenced as soon as warm weather opens up.

Parties have been in Rice Lake, Wis., several times of late looking over the situation regarding a new telephone system in that city. Eau Claire people are said to be interested in the proposition and a fight will probably be made for a franchise. The local people have interested themselves in the movement to a certain extent and it is said that if a franchise can be secured the work of putting in the line will be begun at once. If put in it is expected that connection will be made with Chippewa Falls, Eau Claire and other points in the vicinity.

The movement recently set on foot in Chesterfield, Va., for organizing a local telephone company to effect a telephone system connecting the Court House with Chester, Kingsland, Drewry's Bluff and perhaps other points, is progressing well and assuming business-like shape. E. W. Ellison, of Chesterfield, has been one of the most active and enthusiastic promoters of the movement, and has succeeded in interesting citizens enough to unite as a joint stock company and begin operations as soon as a charter can be secured.

At the close of the convention of the Michigan Independent Telephone Association the following officers were elected to serve during the year, the only changes made being in two members of the executive committee. The complete list follows: President, E. B. Fisher, Grand Rapids; vice-president, R. B. McPherson, Howell; secretary, C. F. Brown, Alma; treasurer, R. F. Johnson, Saginaw. These, with William Robinson, Muskegon; W. O. Hunt, Adrian; J. Robinson, Benton Harbor; A. E. Palmer, Kalkaska, and W. E. Wing, Grass Lake, constitute the executive committee.

The Morning Star Telephone Company is to operate in Crawford, Orange, Dubois, Perry and Harrison Counties, Ind. Its directors are Joseph Allen, W. H. Williams, W. J. Trusty, C. E. Newkirk and G. W. Wilson.

Telephone Incorporations.

The Middletown Home Telephone Company Middletown, O. Capital stock, $10,000. Incorporators: Albert Emanuel, Charles N. Bosler, N. P. Ramsey, Robert E. Cline and H. P. Miller.

The Glidden Telephone Company, Glidden, Wis. Capital stock, $24,000. Incorporators: J. R. Whitaker, W. L. Schuppert and four others.

The Faller Automatic Telephone Exchange Company, New York City—to manufacture telephone apparatus. Capital stock, $10,000. Incorporators: James W. Chisholm, Clarkson Clothier and Ernest A. Fuller.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Aberdeen, Miss.—The Aberdeen Electric Light & Power Company has been incorporated with a capital of $15,000, by E. M. Jones, J. R. Jones, C. C. Stubbs and others.

Alton, Ill.—The proposition of J. F. Porter to light this city with electric lights for the coming year is being discussed.

Braddock, Pa.—The movement for an electric light plant here has gained ground since the election.

Campeche, Mex.—This city is to have an electric light system and the machinery will soon be ordered from the United States.

Cardington, O.—The Cardington Electric Light, Heat & Power Company, has been incorporated with a capital of $15,000.

Charlotte, N. Y.—The matter of improving the electric light and waterworks plant is being discussed by the taypayers of this city.

Clifton Springs, N. Y.—At a public meeting lately held here it was moved and carried to request the village board of trustees to submit two propositions at the election on March 15, one proposition to the effect that a sum not exceeding $18,000 be raised by tax for the purpose of building and equipping an electric light plant, and the other that the sum of $3,500 be raised by tax for the purpose of lighting the village by electricity oa a contract.

Drayton, N. D.—This village may secure an electric lighting plant.

East Lake, Ala.—The citizens will vote on March 28 upon the question of the issue of $13,500 of bonds for the purpose of building an electric light plant.

Fort Branch, Ind.—W. C. Polk and associates are interested in the proposed new electric light plant.

Garden, Mich.—The village council has granted a 20-year electric light franchise to local men and a plant is to be installed soon.

Gobleville, Mich.—A petition is being circulated asking the village council to call an election to vote on bonding the village for $20,000 to put in an electric light and waterworks plant.

Groton, S. D.—A franchise for an electric light, gas and central heating plant here has been granted to Herman E. Miles, of St. Paul, Minn.

Kalama, Wash.—The Kalama Electric Light & Power Company will have the 900 hp. electric plant completed in about two months.

Kensington, Md.—The matter of bonding this city for $50,000 for waterworks, sewers and an electric light system was lately recommended by the mayor and council.

La Grande, Ore.—The Oregon Power & Development Company has been incorporated with $250,000 capital, and proposes to begin the installation of a 7,000 hp. electric light plant on the head water of the John Day River early this spring. F. E. Hobson, F. S. Slater and Z. J. Martin are interested.

Laton, Cal.—The chamber of commerce is considering the formation of a company to erect an electric light plant here. E. P. Blanchard and A. G. Smith are interested.

Lincoln, Neb.—An ordinance is before the council to vote on a bond issue at the April election for a municipal electric lighting plant.

Lockport, N. Y.—A resolution has been passed by the common council directing an election on a proposition to install a municipal electric lighting plant in this city at a cost of $50,000.

Mechanicsville, Ia.—D. C. Gilliland has purchased the electric light plant.

Middletown, Ill.—This city will soon be equipped with an electric light plant.

Minot, N. D.—It is reported that an extended addition to the Minot electric light plant may be made this spring.

Monticello, Wis.—The village board has adopted resolutions in favor of bonding the village for $8,000 to build and operate an electric light plant. The citizens will vote on the proposition March 11.

Needles, Cal.—A franchise for an electric pole line system has been granted to Daniel Murphy, and he proposes to install an electric light and power plant here.

Ogden, Ia.—Bids will be received until March 15 for the erection of a light plant for the town. Plans and specifications may be had of J. M. Rosen, village recorder.

Oxford, N. Y.—Local men are considering the advisability of installing an electric light plant to light the town from the north end to the Webster line.

Port Lavaca, Tex.—A new electric light and ice plant will be installed here by C. J. Spittol.

Santa Clara, Cal.—A new incandescent system of lighting will be constructed here. The estimated cost is $5,000. E. E. Moore is city engineer.

Sedalia, Mo.—Mayor Babcock will soon lay before the city council plans for an electric lighting plant.

St. James, Mo.—Charles W. Orendorf and J. W. Scott, of St. Louis, were lately granted a franchise from the council of this city, for the putting in of an electric lighting plant.

St. Paul, Minn.—The Union Manufacturing Company of St. Anthony's Park, whose electric light plant was recently destroyed by fire, will be rebuilt at once.

Valatie, N. Y.—This village proposes to construct an electric light plant to cost $12,000. E. Lasher is village president.

Valley City, N. D.—A new electric light plant is being discussed here.

Warrensburg, Mo.—This town will soon vote on the proposition to own its electric light plant.

Xenia, O.—Harry L. Canfield, manager of the Delphus Electric & Power Company, has petitioned for a franchise to establish a light plant here.

Yreka, Cal.—C. H. Morrison states that two electric light and power plants, one 23,000 hp., and the other 400 hp., will be constructed here.

STREET RAILWAYS.

Allentown, Pa.—The Blue Ridge Electric Passenger Railway Company is trying to secure the right to enter this city.

Columbia, Ky.—W. K. Azbill is one of the promoters of the new road to be built from here to Lebanon.

East Aurora, N. Y.—The Buffalo & Southeastern Railway Company has made application to the city council for a franchise to build an electric line from Main street to Buffalo.

Eddyville, Ia.—The Chicago, Ottumwa & Eastern Electric Railway Company is the name of a new company just formed here to build a line between Council Bluffs and Ottumwa.

Lake City, Ia.—E. E. Ferris, an electric railroad promoter, with J. G. White & Co., of New York, has closed his Marshalltown contracts and announces that he will come here soon to promote a line from here to Rockwell City and Carroll.

Meridian, Miss.—The Meridian Light & Railroad Company has increased its capital stock to $1,000,000, and will issue $750,000 worth of mortgage bonds for the improvement of the property. An entirely new power house with most modern electrical machinery is to be installed.

Newburgh, N. Y.—Edward Winters is trying to secure a franchise to erect a new trolley line.

New Haven, Conn.—Stockholders of both the New York, New Haven & Hartford Railroad and the Fairhaven & Westville Railroad Company, which controls all the trolley lines in this city, have stated that a deal by which the former company acquires the latter has been practically completed.

New York City.—Robert E. Robinson of Dick & Robinson, the firm that is financing the Westchester Railroad Company, states that the road will be operated by electricity, and that the equipment will be similar to that of the subway. If the plans of the company are carried out it will be able to run its trains from either White Plains or Port Chester to the New York City Hall.

Scranton, Pa.—A franchise is being sought by the Scranton & Dalton Electric Railway Company to build a line through to Factoryville.

St. Louis, Mo.—It is reported that the St. Louis Transit Company will issue $8,000,000 new bonds, of which $4,000,000 will be subscribed for in St. Louis, $2,000,000 in New York and the remainder abroad.

Summit, N. J.—The Cross Steam & Electric Railway Company has made application to the common council for trackage rights.

POWER PLANTS.

Charlotte, N. C.—Whitney & Stephenson are at the head of a syndicate about to begin the construction of an immense power plant near here, to involve a total expenditure of about $5,000,000.

Irapuato, Mex.—An electric power plant will be installed here by Richard A. Barkely to furnish power for operating his flour mills, paint works and other industrial concerns.

BIDS WANTED.

Phoenix, Ariz.—The Commissioner of Indian Affairs is inviting sealed proposals until March 23 for furnishing the United States Indian School here with a quantity of electrical material, including wire, insulators, switches, plugs, rosettes and sockets, dry batteries, etc., a full list of which, together with the necessary blank forms of proposal, may be obtained upon application to Charles W. Goodman, superintendent of the school.

NCTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅜@12½c.; Lake 12½@12⅝c.; casting, 12¼@12⅜c.

The politicians seem to be "playing" with Brooklyn Rapid Transit and Consolidated Gas.

The Philadelphia Traction Company has declared the regular semi-annual dividend of $2 per share, payable April 1 to holders of record March 11.

Announcement is made that the New York and Ottawa Railroad, which will be sold at foreclosure in June, will be converted into an electric line.

The Capital Traction Company of Washington, D. C., has declared the regular quarterly dividend of 1¼ per cent., payable April 1. Books close March 14 and reopen April 1.

The Boston & Albany has asked leading electrical companies for bids for the electrical equipment of the "Newton Circuit." The cost of this equipment will be about $2,000,000.

The Twin City Rapid Transit Company has declared the usual quarterly dividend of 1¾ per cent. on its preferred stock, payable April 1. Books close March 19 and reopen April 2.

The directors of the Hudson River Telephone Company organized on Saturday at Albany, N. Y., with U. N. Bethel, a representative of the American Telephone & Telegraph Company as president.

The Interborough Rapid Transit Company of this city has declared a quarterly dividend of 1½ per cent. on the Manhattan Railway Company lease, and an extra dividend of 1 per cent.

Judge Holt of New York appointed as receiver of the Geneva Electric Construction and Equipment Company James R. Sheffield, with a bond of $5,000. The assets are said to be about $15,000.

Plans for the consolidation of the Utica and Mohawk Valley Traction Company and the Syracuse Rapid Transit Company are being worked out, a conference of capitalists having taken place in New York recently for this purpose.

According to an official of the Union Traction Company of Chicago the earnings since January 1 have just about held their own compared with a year ago. Severe weather and loss of theater travel have had their telling effect.

It is stated from Toledo that the Lake Erie, Bowling Green and Napoleon Electric Railway Company has issued and sold $1,000,000 five per cent. 30-year gold bonds, the money to be used to extend the present line to Fort Trenton and Napoleon.

The New York, New Haven & Hartford Railroad Company has issued an official denial that the company has under consideration the purchase of the Connecticut Railway & Lighting Company, which controls the traction system of Bridgeport, Conn.

The American Telephone & Telegraph Company will take $1,200,000 of the Bell Telephone Company's, of Canada, new $2,000,000 issue. The rights to the new stock are selling in Montreal at 2½, and the stock there has declined from 145 to 138, owing to the new issue.

A. D. Nast has succeeded Elmer Washburne as director of the Strowger Automatic Telephone Exchange, and A. G. Wheeler, Jr., succeeded M. Sello as vice-president. President Washburne expresses confidence that the dividend rate of 50 cents quarterly will be doubled this year.

EDITORIAL NOTES.

A Two-Dollar Tax.

During the latter part of 1899 the question was raised as to whether electric current brought into the United States from a foreign country was dutiable. The matter was brought up at that time by the Niagara Falls Power Company of Niagara Falls, N. Y. The company was worried for fear it would be driven against the wall by the Ontario Power Company, situated on the Canadian side of the Falls.

The question as to whether electric current generated in Canada and used to operate machinery in the United States was subject to a tariff duty was a rather difficult one for the Treasury Department at Washington to decide. But following the rule of the Great Napoleon, who used to say, "When in doubt, do nothing," the department did nothing.

But this inaction did not exactly please the generators of electricity in this State and as a result a bill has just been introduced into the Legislature at Albany which provides that any foreign corporation leasing, selling or transmitting electricity from a foreign country into this State shall pay a tax of $2 on every horse power generated and sold in this State. This is of course aimed at the Niagara, Lockport & Ontario Company, which at present is manufacturing electricity on the Canadian side of the Niagara River and sells its product to Buffalo, and also at a couple of other power concerns at Niagara Falls, soon to be put in operation, which propose to furnish electricity for power in this State, and another at Cornwall on the St. Lawrence.

It is doubtful if the bill ever becomes a law, but it would seem too bad that the American companies *on the spot* cannot successfully compete with foreign companies who are obliged to run much longer cables, involving a greater financial outlay.

Cleveland Wants a Pure Water Supply.

Many communities are troubled with impure drinking water and various attempts have been made in the past to kill the bacteria and render the water sterile without however impairing its taste.

The city of Cleveland, O., has taken up the question of a pure water supply and its Council is engaged discussing the advisability of making use of electricity as the sterilizing agent.

Referring to the subject City Electrician John Dunn is reported as saying:

"The plan is extremely simple. I have been assured that the passage of a strong electrical current through the water is sufficient to destroy the germs. It accomplishes this result as certainly as does boiling. To electrolyze the entire water supply of Cleveland is not a difficult matter. It could be accomplished at a very small expense.

"At present no reservoirs are being used, and the water is pumped directly from the pumping station to the consumers. It would be necessary to utilize one of the reservoirs. Then a powerful electric current could be introduced. This would destroy the germs, but it would not make any chemical change in the water. The alkalis which give taste to water would still remain, and the 'flat' taste of boiled water would be avoided. Then the water could be sent directly from the reservoir to the consumers."

It is not quite as simple a matter to purify water by electricity as the above remarks would lead one to believe. However, it has been done and is done successfully at the present time.

Off hand we should think that the so-called Tindal system would be the best

for a city such as Cleveland. This consists in forcing air that has been subjected to the action of a high tension electric current, and thereby ozonized, into the water to be purified. The statistics of a plant of this nature which has been for some time made use of for purifying a portion of the water supply of Paris, in France, show that it costs but .028 of a cent to sterilize about one cubic yard of water, according to which the whole of the Cleveland supply could be treated for probably about $100 a day, which is by no means an exorbitant figure when the beneficial results attained are taken into consideration.

Patents on Artificial Fuels. There is more thought given to the production of artificial fuels than is generally supposed. We have from time to time referred in these columns to various artificial fuels that have been tried abroad, but that many an inventor on this side of the Atlantic has given the subject his attention is attested by a chapter on artificial fuels in Edward W. Parker's report on "The Production of Coal in 1902," which is about to be published by the United States Geological Survey as an extract from the annual volume of Mineral Resources.

Prior to 1902, about 400 patents had been issued in the United States on artificial fuels, but up to the close of 1901 none had proved a commercial success. Mr. Parker gives a list of United States patents granted since January 1, 1902. It remains to be seen whether any of them will be successfully developed. The list includes 37 patents, but contains no mention of fuels made from petroleum or petroleum residue unless used in connection with coal, lignite or peat. Neither does it include any compounds that have for their object the increase of fuel efficiency unless they are used in the manufacture of the fuel itself. Three patents were used on briquetting machinery.

The steady advance in the price of coal —no less than 40 per cent.—which has taken place since 1898 has stimulated experiments looking to the invention of artificial fuels. Results obtained in foreign countries from the use of lignite and peat in briquetted form should encourage producers in the United States to try similar methods of manufacture. Small sizes of anthracite coal formerly wasted are indeed recovered now by washeries from the old culm banks and utilized. A large amount of coal lost in the form of dust or finely pulverized material might also be put into convenient shape for domestic consumption and slack now wasted at many of the bituminous mines in the United States might be used to advantage if compressed into briquettes. There are many indications that the time is not far distant when these neglected fuel resources will all be utilized.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The fourth annual convention of the Iowa Electrical Association will be held at Des Moines April 13 and 14.

The new "musical" scrapers on the elevated railroad cars in Manhattan were subjected last week to their first really severe test and were found wanting. As the sleet fell on the rails it froze and a thin film of ice was formed on the track. The shoes glided over the coating without picking up current and the scrapers made about as much impression on the coating as the shoes. As a result traffic was delayed and trains stalled.

Electric tramway cars in Rome, Italy, are now fitted with postal boxes, the contents of which are collected every quarter of an hour.

The committee of experts sent by the Pennsylvania Railroad Company to England, Scotland and Continental Europe to investigate signal and telegraph systems reports that the methods in vogue in this country are superior, on the whole, to those of the countries visited.

By May 1 Manhattan Island will be a wireless borough, so far as overhead cables are concerned. The one remaining line, that running from 125th street down the west side, will be put underground in six weeks.

As an indirect consequence of the Marienfelde-Zossen high-speed electrical railway trials, experiments are being made on a number of German railway lines with a view to investigating the working conditions of a steam railway service with increased speeds, says the London *Electrical Engineer*. On the Cassel-Hanover line, for instance, the trains tested are made up of gigantic high-speed locomotives and solidly connected six-axle cars, warranting a mean speed as high as 81 miles per hour. This speed would enable the journey between Berlin and Hamburg to be completed in about two hours, and it is stated that two such trains would be sufficient to cope with the present traffic. In the case of these experiments giving satisfactory results, it is thought probable that next summer some specially suitable lines will be arranged for a similar increased speed service, the more so as the Berlin-Zossen trials have shown existing permanent ways (provided they be fitted with heavy rails) to be fully suitable for a similar service. Even in the case of the introduction of electric high-speed railways being postponed for economical reasons, a material improvement in the German high-speed railway service may therefore be anticipated as far as lines with especially dense traffic are concerned.

The employes of the Russian Westinghouse Company have donated one per cent. of their wages for war purposes, amounting to $300 monthly. The company has given $5,000 and will duplicate the monthly offering of its employes.

Power sufficient to operate practically every industry in Duluth, Minn., is to be developed through the harnessing of the headwaters of the St. Louis River.

William Barclay Parsons, chief engineer of the Rapid Transit Commission of this city, will leave New York on March 29 with his fellow members of the Panama Canal Commission. He will return from the Isthmus in time to leave for London in April. He has been appointed one of a commission to examine and recommend transit improvements in that city.

Prof. Charles P. Steinmetz, in speaking before the Labor Lyceum in Schenectady, N. Y., a short time ago, approved the idea of an electrical night school there

It was announced semi-officially Friday that the long-delayed opening of the rapid transit subway of this city will take place early in June. Work on the elaborate programme has already begun, and the speakers selected have been notified of the parts which they will be expected to take. Among the speakers will be Mayor McClellan, President Orr of the Rapid Transit Commission, August Belmont, Chief Engineer Parsons and Contractor John B. McDonald. It is expected also that there will be distinguished speakers from outside the city, including, possibly, President Roosevelt and Governor Odell, who will be invited. Among the guests will by the Mayors of all the principal American cities.

THE NEW SWEDISH ELECTRIC FURNACE PLANT FOR THE MANUFACTURE OF STEEL.

BY FRANK C. PERKINS.

A large number of engineers and inventors in America as well as in Europe have been working energetically upon the problem of the manufacture of high grade steel using electrical power in specially constructed electric furnaces. Considerable progress has been made in this work, and a number of electric furnaces have been constructed and are now in operation producing steel of a very fine quality. By the use of water power, the cost of steel production of the high grade qualities turned out compare very favorably with the cost of other methods. The electric steel furnace seems to occupy a field entirely its own and there seems little question but that it will be employed quite extensively under special conditions in the future.

The accompanying illustration, Fig. 1, shows the electric power house and iron and steel plant at Gysinge, Sweden, where electric furnaces are made use of for the production of steel of excellent quality. An interior view of the power house is shown in Fig. 2

The electric furnaces installed at Gysinge are those designed by Mr. F. A. Kjellin, the furnace last constructed holding 1,880 kilograms, and when charged with cold raw material is capable of producing 1,500 tons per year. The new furnace is supplied with current from a large single-phase alternating current generator recently installed in the power plant and operated by a vertical turbine, which works under a head of only three meters or about 10 feet. This turbine has a speed of 75 revolutions per minute and develops 300 hp. It is directly coupled to a vertical shaft alternator which generates a monophase current at a pressure of 3,000 volts.

Figs. 3 and 4 are views of the interior electric furnace room, the former showing the side of the electric furnace at the time of drawing off the liquid steel, while the latter shows the top of the Kjellin electric steel furnace where the charging of the raw materials is about to be undertaken.

It is held by F. A. Kjellin that in resistance furnaces with electrodes the steel very easily takes up the impurities from the electrodes consumed, and the cost of the electrodes increases the expense of the output, while the carbonic oxide resulting from the oxidation of the electrodes has a very bad influence by preventing the steel from giving off the carbonic oxide dissolved in it.

The steel can be more uniformly heated by passing an electric current of many amperes through the steel and using the heat evolved by the resistance of the steel for smelting. Mr. Kjellin states that as the resistance of the metals when molten is comparatively low, the currents used must be so great that the copper cables have a section at least as great as that of the steel in the furnace. The Swedish inventor, De Laval, tried to avoid these difficulties by using molten slag instead of steel as resistance in his furnace, but it is thought the result was not satisfactory.

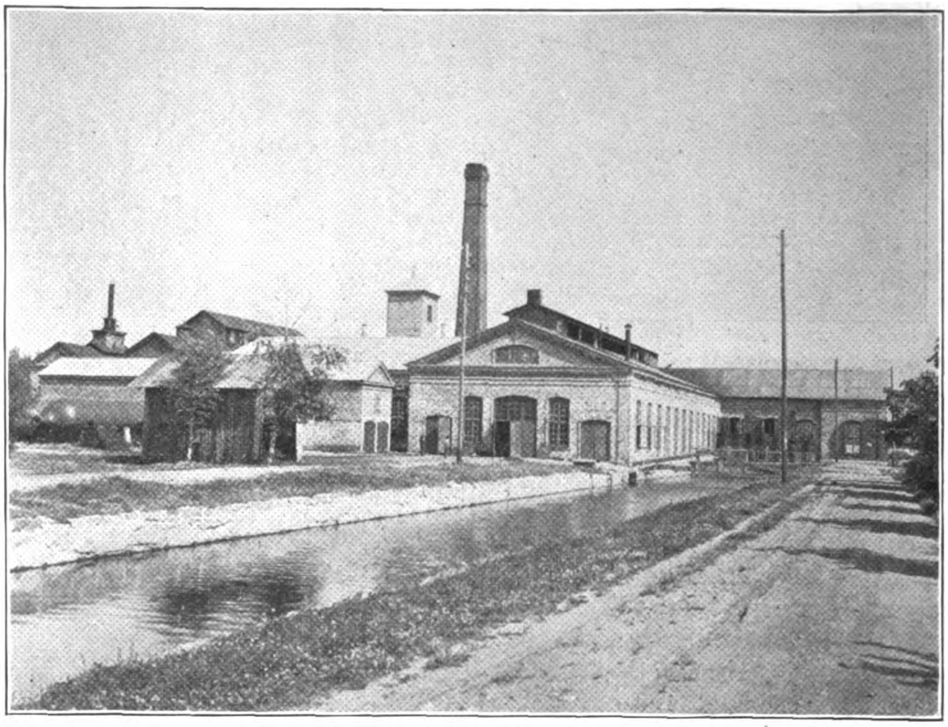

Fig. 1.—Gysinge Plant, Sweden, Operating Kjellin's Electric Steel Furnace.

As the carbon electrodes in furnaces of this kind have high resistance, great losses of tension and power result. Water cooled iron electrodes might be used, possibly, but then the magnetic properties of the iron cause new difficulties to arise.

In order to get sufficient intensity of current alternating currents must be used and then the magnetism causes the concentration of the current at the surface of the electrodes (skin effect) and the result is a great loss of power. On account of self-induction the capacity of the electric generator is also diminished.

In May 1899, in Stockholm, Mr. Kjellin proposed to Mr. Benedicks, general manager of the Gysinge Works, to eliminate these difficulties by constructing an electric furnace without electrodes. This was accepted and the furnaces were built, as shown in Figs. 3 and 4.

The groove forms the furnace chamber, the sides and bottom of which consist of refractory bricks, and covers are used to close the furnace. A quadrangular iron core, formed of thin insulated sheets of soft iron, is in the center of the circle formed by the furnace chamber and this is inclosed by a coil of insulated copper wire. The core continues outside the furnace and forms with the furnace chamber the two links of the chain. An alternator is connected with the coil and the current when passing through the coil excites a varying magnetic flux in the core and this flux induces an alternating electric current in the contents of the furnace chamber.

The operation is, in fact, similar to a step-down transformer having a large number of primary turns and a single secondary turn. The steel in the furnace forms only a single turn around the core, and the current in the steel is then equal to about the primary current in amperes multiplied by the number of turns of wire in the primary coil. The voltage of the current in the steel is of course reduced in the same ratio as the number of amperes are increased. It will thus be seen that it is possible in this way to use an alternating current generator of high tension and yet no transformers are necessary nor copper cables of large sections. The costly and uneconomical carbon electrodes are also avoided, and yet a heavy current is obtained in the furnace with a low voltage.

The first furnace was installed at Gysinge, in February, 1900, and the first ingot was cast on the 18th of March, while it is stated that steel of an excellent

quality was produced from the beginning. This solved the problem from a technical point of view but not from a commercial standpoint, for which an electric generator of 78 kw. capacity it took 24 hours to produce 270 kg. of steel. In November of the same year another furnace was constructed which was able to produce from 600 to 700 kgs. of steel in 24 hours with 58 kw., the charges being 100 kg. every three or four hours. On account of the cooling surface of the walls being too great in comparison to the contents of the furnace the output was not satisfactory and the cost of repairs was too high. In August, 1901, a fire destroyed the sulphite pulp mill at Gysinge, Mr. Kjellin states, and then, instead of rebuilding the same, the water power was utilized for steel making by electric smelting and a new plant was constructed for this purpose. This electric steel furnace plant was started in 1902, and since May of that year has worked extremely well. The furnace shown in the illustrations contained 1,800 kg. of steel, 1,000 kg. being drawn off at a time, the remainder being left to keep the current flowing. It produces 4,100 kg. of steel ingots in 24 hours when charged with cold materials with 165 kw. or 225 electrical horse power.

A single-phase alternating current generator is employed which generates a current of 3,000 volts pressure. This single-phase alternating current is transformed by means of the primary coil and iron core of the furnace into a current of about 30,000 amperes in the steel that forms the secondary circuit.

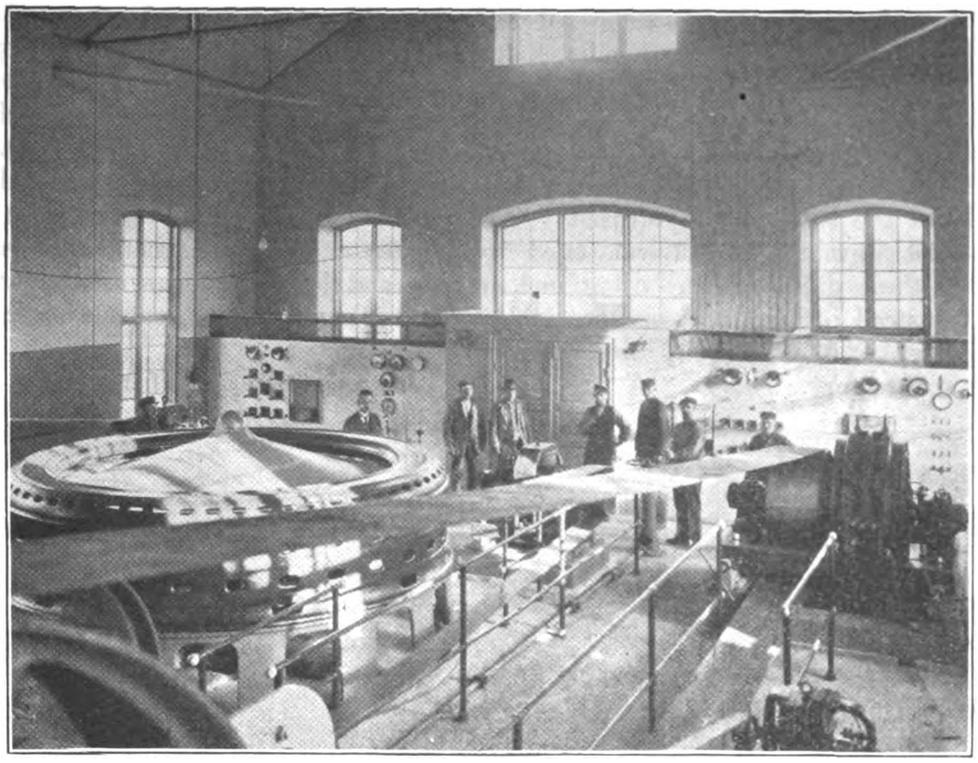

Fig. 2.—3,000 Volt Vertical Single-Phase Generator at Gysinge, Sweden.

At Gysinge there is produced only first-class steel from excellent Dannemore pig iron and wrought iron. The method of operation is as follows: When the steel has been drawn off and about 800 kg. left to keep the current flowing, the furnace is charged with pig iron and bar ends as well as steel scrap in such proportions as the experience has proved will give the percentage of carbon wanted. The resulting steel always has less carbon than the material charged, as the pig iron is usually more or less rusty. When the charge has melted and overheated to a proper degree the metal is drawn off by tapping in the same way as at the open hearth furnace by a hole in the wall of the furnace.

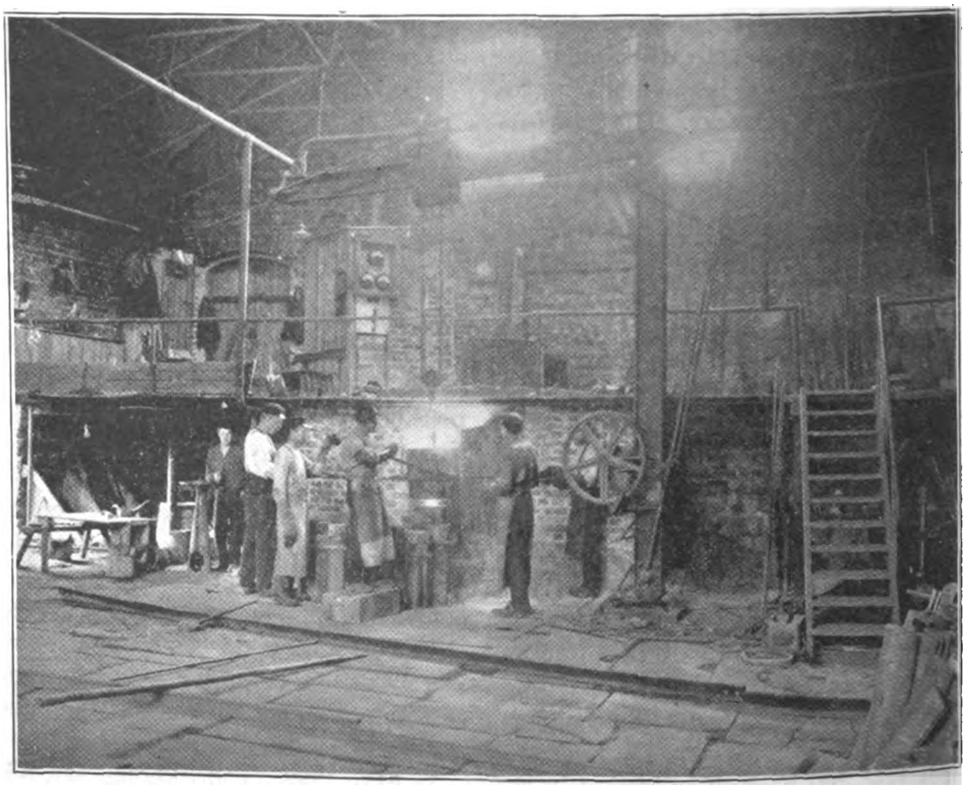

Fig. 3.—Kjellin Electric Iron and Steel Furnace.

As will be noted by the illustrations, the upper part of the Kjellin electric steel furnace is on the same level as the working floor, and the charging is accomplished by simply taking off the covers and putting in the material. As the heat is produced in the steel itself the slag is not so hot as in other steel furnaces, and so the workmen do not suffer from the heat to the same degree.

It is stated that the steel produced is of an uncommonly dense and excellent quality, being homogeneous and unusually tough. It may be easily worked cold when annealed, and is not disposed to crack or warp at hardening as with other kinds of steel. Mr. Kjellin thinks the reason of this is that the steel contains less gaseous matter than other steel, as even small quantities of gases, especially hydrogen, are harmful. He has the following to say in reference to the avoidance of gases in the Kjellin furnace and as to the cost of production of steel ingots:

" By the electric furnace described the steel has no opportunity of taking up such gases or other impurities, and the quality is also better than that of crucible steel with the same analysis. To make special steels with nickel tungsten or chromium offers no difficulties and the alloys are quite homogeneous. The cost

of production depends principally on the efficiency of the furnace and the price of power.

"At the furnace now in use at Gysinge the losses have been experimently proved to be 87.5 kw., so that the effective power absorbed by the steel is 165 — 87.5 = 77.5 kw. and as these produced 4,100 kg. of steel in 24 hours one effective kilowatt produces about 53 kg. steel ingots in the same time. Every kilowatt more in the furnace when the size is not altered increases then the output with 53 kg. steel ingots and we calculate, when we within a few months get a stronger water-wheel, to produce about 6,000 kg. of steel ingots with 200 kw. in 24 hours. As the absolute cost of labor and repair will be the same these costs for one ton of steel ingots will be about two-thirds of the cost now, and the price of power per ton will also be sensibly diminished.

"The cost of repair, that is, of renewing the lining of the furnace of 763 kw. or 1,000 electric hp. will produce 30,000 kg. of steel ingots in 24 hours when charged with cold materials. With hot materials the output is much greater. For instance, if 250 kg. of molten pig iron are charged for each ton of steel ingot produced, the output is increased from 30,000 to 36,000 kg. in 24 hours with electric horse power.

"The cost of labor and repair for such a furnace will in my opinion be less than those of an open hearth furnace of the same size, so that, where power is cheap, there is a possibility of producing a steel competing with the dear crucible steel at a smelting cost not exceeding that of the open hearth furnace."

An estimate of the total cost of producing the steel by the electric furnace is estimated at $42.89, assuming 165 kw. for 4,100 kg. of steel in 24 hours. The cost of one horse power hour being assumed at .375 cent would make the cost of power $5, the wages being $2.50 and the cost of the charge $32.50. The depreciation at interest is estimated at 56 cents, and the cost of repairs and brickwork $2.08, while the cost of the mould is taken as 25 cents. The cost of the charge would be considerably higher if chromium and other expensive material were added, the above estimate of charge being the cost for soft iron and pure charcoal and pig iron. A lining of silica or magnesia stone may be used in this process as the fire gases do not come into contact with the steel even by diffusion. An analysis of one grade of steel made at Gysinge shows a composition of sulphur .01 per cent., phosphorous .011 per cent., with .49 per cent. of manganese and .47 per cent. of silicon, the carbon being represented by 1.45 per cent. The cost of building the electric furnace is given as 1,500 Swedish crowns and it has a capacity of about one ton, the ordinary steel crucibles are usually employed holding about 40 kg. of metal.

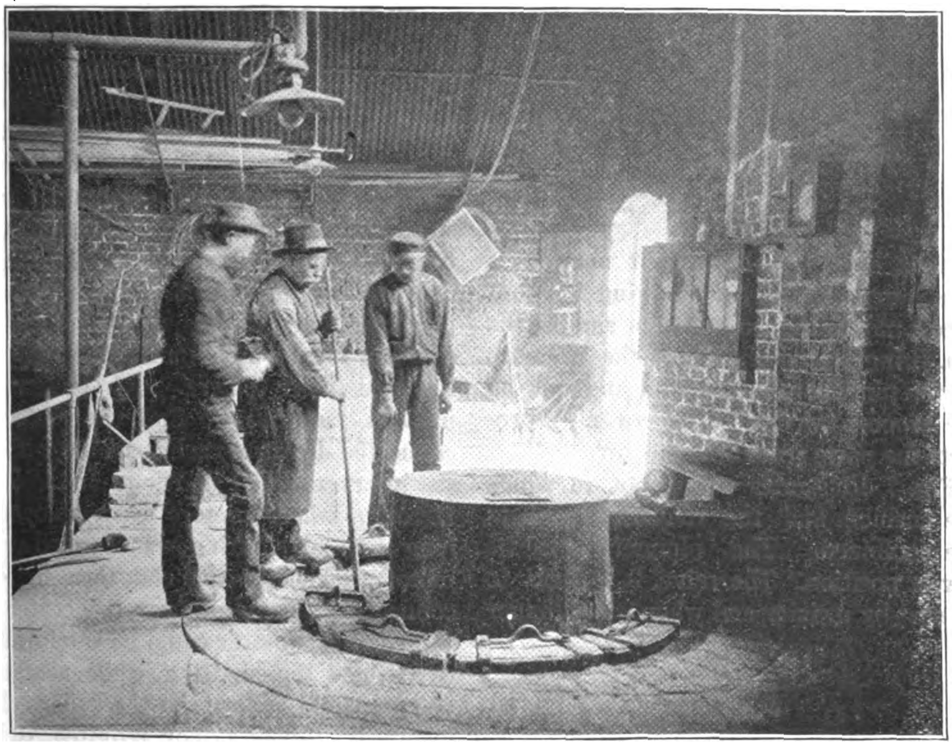

Fig. 4.—Kjellin Electric Iron and Steel Furnace.

Electric Light Statistics.

The United States has 18,000,000 incandescent and 385,000 arc lamps in operation.

DASH POTS FOR CORLISS ENGINES.

ARTICLE III.

BY W. H. WAKEMAN.

Fig. 5 illustrates another kind of dash pot, from which excellent results in practice are secured, because it can be adjusted very accurately. The plunger is made in two parts, one of which is larger than the other, similar to others already described. Air is trapped under the larger part to form a cushion, but its action is such that it may properly be called a compound cushioning device. The plunger is in its lowest position now, but suppose that it is raised until the top of plunger, 2, is level with the top of cylinder, 3. The cut off valve is now tripped, and the plunger begins to descend, causing air to rush through the passage, 4, into the pipe, and thence to the atmosphere.

As the air cannot escape instantly, cushioning is begun before the plunger passes the lower part of this passage, marked 6 in the illustration, but after it passes this point no air can escape except what goes out through the small passage below 4, and this is partially or wholly closed by adjusting the screw, 7, which may be turned at pleasure to give compression enough to prevent pounding. Air from this small passage is also discharged into the pipe, 5, and is conveyed beneath the floor where the noise it makes in escaping is not objectionable. Packing made of leather is placed under this plunger to prevent the two iron surfaces from coming together when the lowest position is reached.

The lower part of this plunger is packed with leather at 8 to assist in preventing air under pressure from passing out of the cushion chamber into the vacuum chamber, 9. A valve, 10, opens outward from this chamber, and is held in place by the spring, 11. The object of this valve is to permit air that finds its way into the vacuum chamber to escape out of the passage 12, and its operation is as follows: When the vacuum plunger rises it draws the valve, 10, to its seat and maintains a partial vacuum in the chamber, but as soon as the plunger descends it compresses air that may have leaked into this chamber, and the pressure so created opens the valve, 10, against the spring, 11, and air goes out of 12.

On a Corliss engine that I had charge of several years ago the vacuum plunger was so large and the vacuum so nearly perfect that it was difficult to provide cushion enough to insure quiet operation without causing the plunger to rebound,

which was not satisfactory. To overcome this objection, a hole was bored through the valve, 10, and a copper pin fitted into it. A flat spot was filed on this pin by means of which a small inlet for air was provided. This plan is better than to file the valve, because the small hole can easily be plugged if it is not wanted, while the valve would be spoiled if it was filed. In this case it resulted in reducing the objectionable noise.

In Fig. 5 the rod is fastened to the plunger by pin, 13, without means for taking out lost motion.

Fig. 6 illustrates a dash pot in which the cushioning chamber, 2, is below the vacuum chamber 3. As the plunger is in its lowest position, neither of these chambers show plainly, but consideration of the cut will make the matter plain. As the plunger rises, air rushes through the inlet, 4, and fills the chamber, 2.

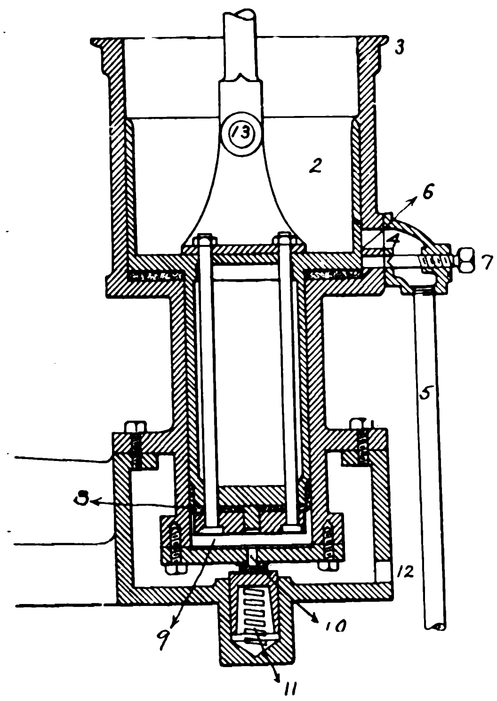

FIG. 5.

when the plunger descends it drives out this air, but the engineer can adjust the screw, 5, so as to throttle it, and thus make a cushion for the plunger.

The leather packing 6 is fixed on the stationary post which forms a central guide for the plunger, and prevents air from passing rapidly into the vacuum chamber, 3.

When the plunger rises it draws the valve, 7, to its seat, but when action is reversed, air that may have entered the chamber, 3, is compressed and opening the valve, 7, against the spring, 8, passes into the open part, 9.

The rod (not shown in the cut), is fastened to the plunger by means of the pin, 10, passing through ears cast on the top of the plunger. This pin is a tight fit in the ears, but loose in the rod, as it must be free to move in two directions. As time passes the pin becomes worn at this point, and as the engine builder has not provided a way for taking up this lost motion, engineers sometimes drive in a wooden wedge, as shown at 11. While

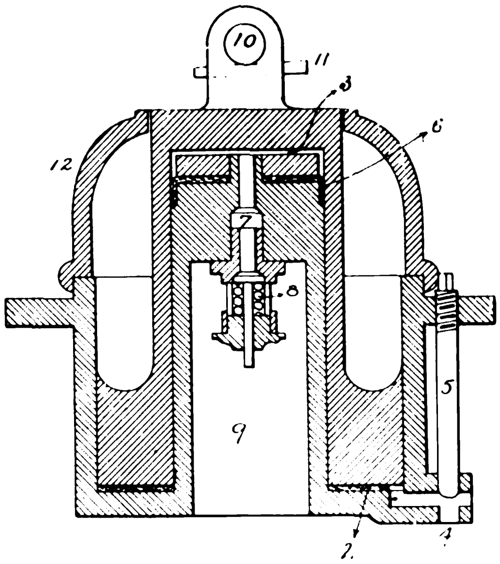

FIG. 6.

this is only a makeshift, it answers a good purpose, for by renewing it about once a month the rod is kept against the pin, bringing nearly all of the pressure on the pin where it belongs, and not on the wooden wedge. The cover 12 protects the parts from dust and dirt.

Fig. 7 illustrates a dash pot in which the cushion and the vacuum chambers are combined. The plunger is in its lowest position. The valve, 2, is held to its seat by gravity and when the plunger

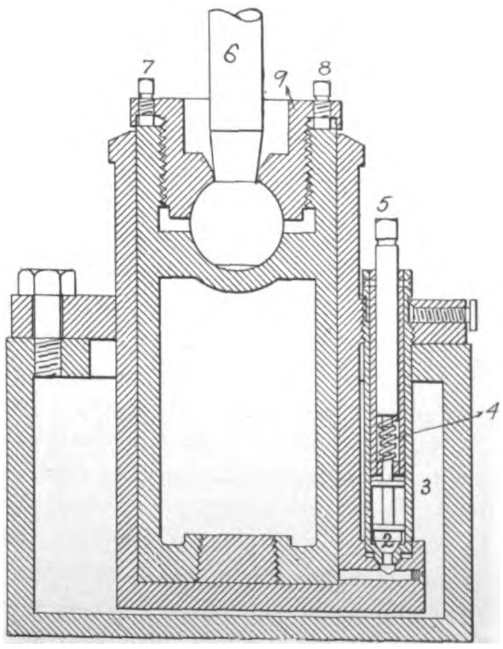

FIG. 7.

is drawn upward this valve is forced downward by external air pressure acting on the top of it.

This insures a partial vacuum under the plunger, and allows air to press upon the top of it effectually, as already explained. When the plunger descends it compresses whatever air may be found in this chamber, thus cushioning the plunger, lifting the valve, 2, and forces air out into the passage 3. This action is opposed by the spring, 4, the tension of which is regulated by the screw, 5.

The dash pot rod, 6, terminates in a ball and socket joint, provided with a very ingenious device for taking out lost motion due to wear. The check screws, 7 and 8, are loosened, and the nut, 9, is turned down until it touches the ball, but does not bind it. The check screws are then tightened holding the adjusting nut in place, and the job is done.

ELECTRIC-DRIVEN PLANTS.

BY WILLIAM KAVANAGH.

Now that the application of the electric motor for power purposes is well understood every practical engineer should endeavor to obtain all the information possible upon the motor and its application to general machinery. When the motor first became prominent as a means of power delivery it was usually belted to shafting from which individual machines received their power. At present in modern factories we find the motor is connected direct to each machine without the intervention of shafting. In the older factories where motors are employed a long line of shafting was erected and a motor attached to each end, then by disconnecting a coupling near the center of the shaft one motor could be employed to drive half the shafting, while necessary repairs could be made to the other. For instance, suppose a floor required 70 hp. then two 35 hp. motors would be employed. This method of driving the shaft is being rapidly superseded by attaching the motor direct to each machine. While the individual application of motors subdivides the power it involves a greater amount of labor on the part of the electrician. Controllers, starting boxes, switches, fuses, etc., multiply and require constant supervision. The old style of delivering power is becoming less every day, the ponderous flywheel and belt has disappeared, the motor and direct connected generator having taken its place.

Instead of the large flywheel and belt we have the direct-connected unit so arranged that the distribution of electricity for different purposes is accomplished without involving any expensive arrangement of shafting mules or belts. The generator in general use for power in medium sized plants is multipolar and of the type known as "constant potential,"

that is, the current varies, but the pressure remains nearly constant under varying conditions. If the current varies, say 100 amperes, the pressure or voltage may not vary over five volts. Such generators usually carry a pressure of either 220 or 250 volts, and in some cases current for heating and incandescent and arc lighting is taken from them. When current for incandescent lighting is taken from the power generator fluctuations will occur in the lamps, making it unpleasant for persons who are in need of steady light. The fluctuations are more pronounced at the moment a heavy load is thrown on or off the generator. In order to obviate these fluctuations some plants are equipped with an independent lighting system. The installation of an independent lighting plant increases the first cost to a considerable degree. In order to lessen this expense some plants are equipped with what is known as the "balancing set," which partially accomplishes the desired result. Where a balancing set is employed, the three-wire system is utilized for lighting and heating purposes, while the two-wire is used for power. The current for operating the balancing set is taken from the main bus bars by means of a two-pole switch, which in turn is connected to a starting-box, the current is carried from the starting-box to the balancing set, which puts it in operation. The balancing set might be called a twin motor having the series windings of its fields connected to the middle bus bar through the medium of a single pole switch. To start the balancing set build up voltage and close the main switch; now close the two-pole switch that is connected to the starting box and cut out resistance; immediately the balancing set will begin to rotate. When all resistance of starting box is cut out close single pole switch. Our lighting system is now ready for use and the current will be balanced from one side of the three-wire system to the other side, according as the demand for current arises on either side. Unless the demand for current is very great and fluctuating at the same time we will obtain a steady light while the balancing set is in operation. Where such a set is employed we are enabled to use either 125 or 250 volts, assuming our generator carries 250 volts. By connecting from the middle wire to either of the outside wires we obtain 125 volts; if we connect to the two outside wires direct we will get 250 volts. It appears that when the balancing set is not in operation we must pull or open all of the lighting switches; we may then run with our power switches closed. Should we leave any of our lighting switches closed when the balancing set is stopped our lamps will surely be burned out. Should any attempt be made to light them in all probability the insulation on our light wires and flexible cord will be destroyed. Where a balancing set is used our power switches will be two-pole and our lighting switches three-pole. Our switchboard will be equipped with four measuring instruments as follows: One voltmeter, one balancing meter that indicates which side of the system is carrying the most current, one main ammeter that registers the total amount of current generated, and one ammeter that indicates the amount of current used for power. Should we wish to calculate the power distributed from such a board it will be necessary to read the amount of current indicated on the two ammeters. Suppose our main ammeter registers 500 amperes and our power ammeter 300, then the electrical horse power will be

$$\frac{(300 \times 250) + (200 \times 125)}{746}$$

instead of $\frac{500 \times 250}{746}$, because we are sending out on the power line 300 amperes at a pressure of 250 volts, and on the lighting and heating lines 200 amperes under a pressure of 125 volts. Some engineers make the mistake in multiplying the amperes indicated on the main ammeter by 250, which is not correct. Others take the sum of the amperes, which is also wrong. Let us take the above case. We see that the result would read $\frac{800 \times 250}{746}$, which would equal 268 hp., whereas the correct answer is 134.04 hp.

ELECTRICAL STATION PRACTICE.

ARTICLE XXVIII.

BY W. H. RADCLIFFE.

The starting, stopping, and general operation of rotary converters form an important part in the routine of many sub-stations. As to the starting of these machines for the purpose of converting alternating current into direct current, any one of several methods may be employed, the choice in any given case depending upon which of them may best be followed under the existing conditions.

If it is found advisable to start the converter with direct current, the same connections would be made between the source of the direct current and the armature terminals on the commutator side of the converter as would be the case were a direct current shunt motor of considerable size to be started; this naturally means that a starting rheostat and a circuit breaker will be introduced in circuit. The shunt field winding alone is used, and this part of the winding may be made permanent if, as is usually the case, the same source of direct current is used normally for separate field excitation. The direct current may be derived from a storage battery, from a separate converter, or from a motor-generator set installed in the sub-station for the purpose. An adjustable rheostat will, of course, be connected in the field circuit for regulation. Before starting the converter, however, it is necessary to do certain wiring between the terminals on the collector side of the machine and the alternating current supply wires, in order that the change-over from direct current motive power to alternating current motive power may be made when the proper phase relations are established between the alternating current in the supply wires and the alternating current in the armature winding of the converter.

In order that proper phase relations exist, the armature of the converter must rotate at such a speed that each coil thereon passes its proper reversal point at the same time as the alternating current reverses in the supply wires. This speed may be calculated by doubling the frequency of the supply current and then dividing by the number of pole pieces on the converter, but a far more accurate method of judging when the converter is in step or in synchronism with the supply current consists in employing incandescent lamps as shown in Fig. 28.

In this illustration the alternating current side of a three-phase converter is shown at *c*. The three brushes, *d*, *t* and *g* pressing on its collector rings are joined in order to the three single-pole switches *h*, *l* and *b* which can be made to connect with the respective wires *m*, *r*, and *v*, of the supply circuit. Across one of the outside switches, *h*, for example, a number of incandescent lamps are joined in series as indicated at *e*, while the switch (not shown) in the main circuit, is open. If then the main switch just mentioned and the middle switch *l* be both closed, and the armature of the alternator be brought up to normal speed by running it as a direct current motor, the lamps at *e* will light up and darken in rapid succession; the lighting and darkening of the lamps will continue until, by a proper adjustment of the speed, the correct phase relations be established between the current supplied by the alternator and the alternating current in the armature of the

converter. As this condition is approached, the intervals between the successive lighting up and darkening of the lamps will increase until they remain perfectly dark. There is then no difference of potential between the supply circuit *m r v* and the rotary converter armature circuit, so the source of the direct current may at that instant be disconnected from the machine and the switches *h* and *b* closed. If the change-over has been affected before the phase relations of the two circuits differed, the converter will at once conform itself to the alternator circuit and run thereon as a synchronous motor without further trouble. The opening of the direct current circuit and the closing of the alternating current circuit may be done by hand, but preferably by employing a device that will automatically trip the circuit breaker in the direct current circuit at the instant the switches in the alternating current circuit are closed.

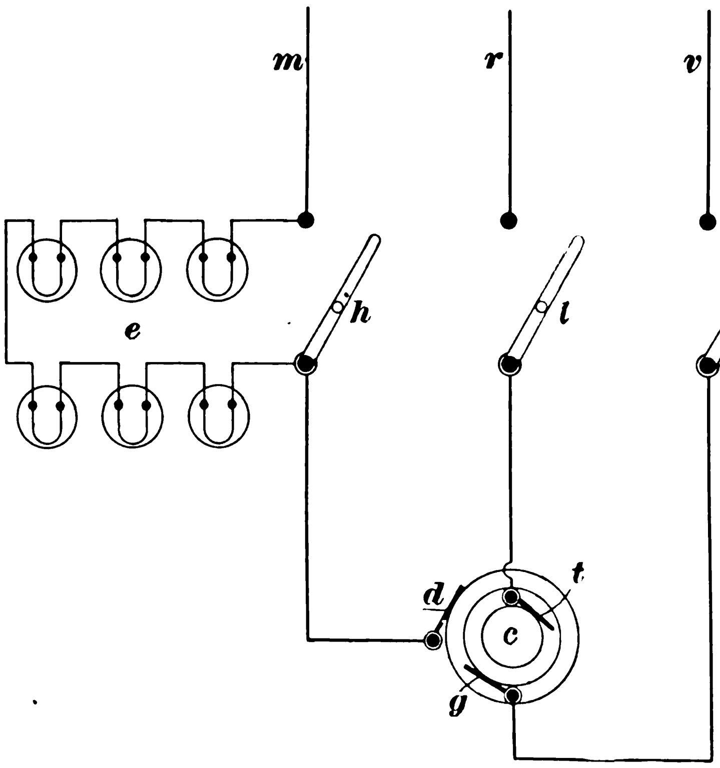

FIG. 28.

If the rotary converter be of the polyphase type and it be desired to start the machine with alternating current, this may be done by applying the alternating electromotive force directly to the collector rings while the armature is at rest. There need be no field excitation; in fact the field windings on the separate pole pieces should be disconnected from each other before the alternating electromotive force is applied to the armature, else a high voltage will be induced in the field windings which may prove injurious to their insulation. The passage of the alternating current through the armature winding produces a magnetic field which rotates about the armature core and induces in the pole pieces eddy currents, which reacting on the armature exert a sufficient torque to start the converter from rest and cause it to speed up to synchronism. The alternating current required to start the converter in this way greatly exceeds its normal full load value, sometimes to an extent of 100 per cent. To reduce this starting current, transformers may be switched in circuit temporarily to reduce the line wire voltage until the speed has become normal.

A convenient means is afforded, when starting the converter by this method, for ascertaining when the converter is running in synchronism with the alternator supplying it, and when therefore the field circuit may be closed and the load thrown on. Reference is here made to the connection of incandescent lamps across the brushes pressing on the commutator, or across the leads connected therewith. In starting, there is an alternating current between the brushes which pulsates very rapidly, but when synchronism is approached the pulsations become less rapid until finally with the converter in step with the alternator the pulsations entirely disappear. The light given by the lamps connected, as previously stated, indicates accurately the condition of affairs at any one time, varying from a rapidly fluctuating light at the beginning to one of constant brilliancy when synchronism is attained.

The most modern method of starting rotary converters is to mount on an iron bracket cast in with the converter frame, a small induction motor of the polyphase type whose armature shaft is keyed to that of the converter. The bracket, and therefore the motor, is usually mounted outside the armature bearing on the collector side of the converter. Allowing for a certain amount of slip in the induction motor, the field of this machine must possess a less number of magnet poles than the converter in order to enable the latter machine being brought to full synchronism. To start the induction motor it is simply necessary to apply to its field terminals the proper alternating electromotive force. If its armature is provided with a starting resistance to reduce the current at the beginning, this resistance must be in series with the armature conductors before the alternating electromotive force is applied. As the motor increases in speed, the starting resistance is gradually short-circuited until it is entirely cut out of circuit. In all standard types of induction motors the starting resistance is mounted within the armature spider and is adjusted by means of a handle which may be moved in or out while the armature is rotating.

The usual wiring for the installation of a rotary converter in a sub-station commencing at the entrance of the high pressure cables is first that for the lightning arresters, then for the connection in circuit of the high tension switching devices, from which the conductors are led to bus bars, and thence to the step-down transformers. On a three-phase system the transformers should be joined in delta connection, as thereby a considerable advantage is gained over the star connection, in that should one of the transformers become defective the remaining two will carry the load without change except more or less additional heating. Between the transformers and rotary converter the circuits should be as short and as simple as possible, switches, fuses, and other instruments being entirely excluded. The direct current from the converter is led to the direct current switchboard, and from there is distributed to the feeder circuits.

In large sub-stations where several rotary converters are in operation they may often be found receiving their respective currents from the same set of bus bars; that is, they may be operated as alternating current motors in parallel. They are also, however, frequently operated independently from single bus bars, but very seldom in series with each other. The direct current circuits of several converters may, if desired, be connected together in multiple and give satisfactory results. As in central station practice, provision should be made against inter-

ruption of service from the sub-station by providing therein one reserve rotary converter to every three or four converters actually required.

A rotary converter in operation generally produces more satisfactory results and requires even less attention than does a direct current generator delivering the same output. The reasons for this are, there is less friction loss; there is less armature resistance, since the alternating current at certain portions of each revolution passes directly to the commutator bars without traversing the entire armature winding as it must necessarily do in a generator; there is no distortion of the field and consequently no sparking, or shifting of the brushes, since the armature reaction resulting from the current fed into the machine and that due to the current generated in the armature completely neutralizes each other.

There are, however, certain detrimental features characteristic of rotary converters that should not be overlooked. Of these may be mentioned that of voltage regulation. The direct current voltage developed can be maintained constant only by preserving uniform conditions of inductance in the alternating current circuit, and uniform conditions in the alternator. While changes in either of these may be compensated to a certain extent by adjustment of the field strength of the converter, they cannot be entirely neutralized in this manner; it is therefore necessary that both the line circuit and the alternator be given attention if the best results are to be obtained from the converter.

Another detrimental feature of the rotary converter is that it possesses a tendency to run at varying speeds regardless of the impressed voltage; this is caused by a variation in frequency and is known as hunting. Whereas the inertia of the converter armature tends to maintain a constant speed, variations in the frequency of the supply circuit will cause a displacement of phase between the current in the armature and that in the line wires, which displacement, however, the synchronizing current strives to decrease. The synchronizing current, although beneficial in remedying the trouble after it occurs, exerts but little effort in preventing it, and many minds have spent many hours in many ways striving to devise some plan whereby this trouble might be eliminated. Of the methods in use at the present time for the prevention of hunting there are the employment of a strongly magnetized field relatively to that developed by the armature, a heavy flywheel effect in the converter, increasing the inductance of the armature by sinking the windings thereon in deep slots in the core which slots are provided with extended heads, and the employment of damping devices on the pole pieces of the converter.

It is generally admitted that the damping method has proved to be the most effectual remedy for hunting. The devices employed for the purpose are generally copper shields placed between or around the pole pieces, although in some converters the copper is embedded in the poles, and in others it is made simply to surround a portion of the pole tips. In any case its action is as follows: The armature rotating at a variable speed has a field developed therein which is assumed to be also rotating at a variable speed; the magnetism of this rotary field induces currents in the copper which, however, react on the armature and oppose any tendency toward a further shifting of the magnetism in the armature and therefore prevent the development of additional currents in the copper. Since copper is of low resistance, the induced currents are sufficient in strength to thus dampen any tendency toward phase displacement and so exert a steadying influence upon the installation as a whole.

Although rotary converters, as has just been shown, are not without objectionable features, they may at the same time be said to constitute the most practical and efficient machines that can be installed in a sub-station for the conversion of alternating currents from the transmission line into direct currents for distribution.

PRESENT INDEPENDENT TELEPHONE SITUATION.*

BY J. B. WARE.

This State Association was one of the first to be formed and was organized in 1897, seven years ago.

While several States claim to be the birthplace of the Independent movement, Michigan seems to have as good ground for such claim as any. Whatever difference there may be as to the birthplace, I feel confident that few, if any, acquainted with the history of the movement, will question our right to claim Michigan as the home of this enterprise in its childhood days, and that its present proportions are largely the outgrowth of the early start and the strength which it obtained on Michigan soil. Not alone was one of the first opposition exchanges built in our State, but Michigan was the first to have an Independent exchange in operation, numbering 500 telephones; also the first to have 1,000, also 2,000 and 5,000; also the first to have an automatic exchange with 500 telephones in service; also the the first in which an opposition company put up copper metallic toll circuits. I regret to recall to your attention that our State was also the first having in it men who planned to succeed as Independents, and then betray the movement, by sale, to the Bell interest, and that these men so nearly succeeded in their treacherous attempt, as to cause in the minds of many, even to this day, suspicion to rest on telephone men in general, as their honesty and uprightness.

Thus we have in our State's telephone history, and within the short space of seven years, the two extremes of honorable and dishonorable record; but, as must always be true, honesty does pay, and success has crowned the honest effort.

In addition to the record already mentioned, we have, in common with many other States, the satisfaction of having seen the Independent movement a constantly increasing success year by year, until to-day there are in the United States, more Independent telephones in use, than there are Bell telephones by exchange subscribers; and that as a rule, those using Independent are receiving much better exchange service than are those using Bell instruments; and, further, the Independent companies have proven financially successful, with exceedingly few exceptions.

Until about 1895, the Bell interests had no competition in the telephone field, and there were no successful opposition companies previous to eight years ago.

It is not my purpose to review the history of the Independent movement, but to mention briefly a few facts and figures which indicate, though inadequately, the present condition of the movement in different sections of our country.

The Independent telephone development has been most rapid and successful in the Middle and Central Western States where it started, and is most retarded in the extreme Eastern States.

Thus in the six New England States, a very populous section of our country, there are fewer Independent telephones in service than in each of more than 20 other States in the Union.

The reason for this condition is generally and rightfully understood as being, principally, because of the political influence of the Bell Company in the territory named, which, united with that of the Boston & Hartford Railroad interests, apparently have absolute control of legis-

* Paper read at the annual convention of the Michigan Independent Telephone Association held in Detroit, Feb. 25, 1904.

lation in the majority of these States. The difficulties in securing franchises for opposition telephone plants, are almost insurmountable, and are greater than in any other section of our country.

Another factor, however, not generally understood, has bearing on the situation named, being the restrictions placed on the use of the automatic apparatus, under Strowger patent, by reason of the heavy royalty charged in certain of these States.

The automatic apparatus named first secured a foothold in these Eastern States, over the most of which the Eastern Automatic Telephone Company secured exclusive rights to use apparatus manufactured under said patents. This company, having its headquarters in Boston, the home of the Bell Company, followed the ruinous Bell policy of charging such a heavy royalty on each telephone used as to almost prevent the use of the automatic apparatus in the States named. While this same condition formerly existed in other sections of the country, fortunately for the Independents, the Strowger patents are now owned and controlled by the Automatic Electric Company of Chicago. This company, like all other Independent telephone manufacturing corporations, sells outright its apparatus and telephones, upon which there is no royalty. It has secured the State rights of all such companies, other than the Eastern Automatic, and is endeavoring to obtain such rights from that company, in order that there may be no royalty burden in the Independent field. It is to be hoped that it may succeed in removing this unfortunate and unreasonable burden from this unfortunate section of our country.

However, in the New England States, valuable development has already taken place; thus in Massachusetts are the Fall River and New Bedford exchanges; in Maine, the Portland exchange. These, with others in smaller cities, give evidence of a splendid telephone development which we may expect in the very near future will be realized in this home territory of the Bell Companies.

In the State of New York, outside of New York City, the Independents have occupied every city and town of importance and operate more telephones than do the several Bell companies occupying that territory. The estimate of the number of Independent telephones in the western half of the State is 45,000, and for the eastern half 30,000, a total of 75,000.

In a majority of cases, the larger exchanges in New York have been built in the last two years, and the greater number of those having 500 or more telephones in operation are the central energy type of exchanges.

The toll line and long distance construction is modern; especially is this true in Western New York, where the poles used are principally 30 ft. cedar, with 8 inch tops, and the copper circuits not smaller than No. 10. No better construction has been made by either Bell or Independent interests in any State.

Of the cities having Independent exchanges in operation, are Buffalo, with 7,000 telephones, and Rochester having over 6,000 telephones; Troy with 4,000; Albany, Utica, Syracuse, Binghamton and Jamestown, averaging 2,500 each; Herkimer, Glens Falls, Saratoga Springs, Schenectady, Rome, Cortland, Ithaca, Elmira, Hornellsville, Geneva, Auburn, Johnstown and Niagara Falls averaging over 1,000 each. The Independents have more telephones in service in these 21 cities named than have the Bell Companies. In four of the cities, the Bell has the larger number of telephones; in 12, the Independents have the larger number, and in the remaining five the numerical strength is equal. In the smaller cities, villages and rural communities throughout the State, without any noticeable exception the Independents have much better development than have the Bell licensees. The conditions to-day, and the outlook, is most favorable to the Independent.

In New Jersey and Pennsylvania all important cities and towns have been occupied by Independent companies; thus, in Philadelphia, there are nearly 12,000 Independent telephones in service; in Pittsburg and Allegheny, over 11,000; in Paterson and Trenton, N. J., and in Scranton, Wilkes Barre, Erie, Harrisburg and other important Pennsylvania cities, the Independent telephones largely exceed those of the Bell. In the smaller cities and towns throughout these two States the Independents have been even more successful than in the larger.

The State of Mayland has been well developed, the Independents in Baltimore having over 8,000 telephones in service previous to the recent fire. The three States of New Jersey, Pennsylvania and Maryland, have good long distance toll line development with Philadelphia as a center. (It is interesting to note at this point that Philadelphia has a toll board of 21 positions, being the largest in the Independent field, with one exception.)

In Virginia and in the Gulf States much progress has been made by the movement during the past two years. Exchanges have been established among the important cities, such as Norfolk, Va.; Columbia and Charleston, S. C.; Jacksonville and Tampa, Fla.; Atlanta, Augusta and Savannah, Ga.; Birmingham and Mobile, Ala.; San Antonio, Waco, Ft. Worth, Houston and Austin, Tex., besides many exchanges in the smaller cities and towns in the States named. While in Florida and others of the States, the development has been rapid, yet in Texas the development has been most remarkable. In this State not a city or town of importance but has an Independent exchange in operation, or one rapidly approaching completion. The character of construction is excellent and the long distance toll lines now building and planned insure for Texas in an exceedingly short time adequate exchange and toll service.

In the States of Tennessee, Kentucky and West Virginia, some very satisfactory development has been made. The cities of Vicksburg and Memphis, Tenn.; Lexington, Louisville and Knoxville, Ky.; Charleston and Wheeling, W. Va., are perhaps the most prominent of the Independent exchanges. These, with numerous other exchanges in the three States, have already secured long distance toll connections with the States to the northward, Ohio and Indiana particularly.

These last two mentioned States are foremost in telephone development. In Indiana, all cities, towns and villages, with hardly an exception, are successfully occupied by the Independents, and fine long distance lines have already been completed; so that, second only to Ohio, its telephone development is the most complete of any in the United States.

In Ohio, the entire State with the single exception of Cincinnati, has been occupied by the Independents with their exchanges and toll lines. So complete has been this development it is unnecessary to enumerate any of the cities occupied.

The relative strength of the two interests, numerically, in the States mentioned is as follows:

	Independents.	Bell.
Ohio..........	145,000	89,000
Indiana........	107,000	40,000
Total........	252,000	129,000

being nearly "two to one."

Besides numerous small exchanges in Minnesota, the cities of St. Paul, Minneapolis and Duluth have large successful exchanges in operation, with more telephones in service than have the Bell Companies in said cities.

(*To be continued.*)

Prof. Owens on Interior Electric Wiring.

Prof. R. B. Owens of McGill University, lecturing before the Insurance Institute of Montreal on "Interior Electric Wiring," gave the three conditions which must be fulfilled to involve the minimum risk to property and life. First, the conductor system must be of such ample current carrying capacity that there would be no overheating of the conductors, which would mean probably fire of some sort. In the second place, the conductor must be so insulated as to render it harmless with regard to shock and also to prevent any leakage of the current, which might cause fire. Third, no conductor system could be considered properly installed unless all the best known current pressure limiting devices were attached to it. There are three systems of interior winding—open cleat, molded and conduit. The last named was the only one that could be relied on with safety. With a properly insulated conduit system, he believed, there would be no chance of danger.

American Institute of Electrical Engineers.

The following papers relating to high-pressure transmission matters are contained in the January number of the "Transactions:"

"The Relative Fire-risk of Oil and Air-blast Transformers," by E. W. Rice, Jr.

"Use of Group-Switches in Large Power Plants," by Louis B. Stillwell.

"Oil Switches for High Pressures," by E. M. Hewlett.

"Terminals and Bushings for High-Pressure Transformers," by Walter S. Moody.

These papers will be discussed at the meeting to be held at 108 West 55th street, New York, March 25.

Examination for Assistant Electrical Engineer.

The United States Civil Service Commission announces an examination April 6-7, to secure eligibles from which to make certification to fill vacancies in the position of assistant electrical engineer in the Signal Service at Large, Washington, D. C., at $1,400 per annum, and other similar vacancies as they may occur. Two days will be required for this examination; age limit, 20 years or over. Applicants for this position should have a good general knowledge of electrical science, and should be thoroughly familiar with telephone, telegraph and cable engineering.

Electrochemical Society General Meeting.

The fifth general meeting of the American Electrochemical Society, will be held at Washington, D. C., April 7, 8 and 9.

The meeting will be held at the Columbian University, corner 15th and H streets, N. W.

Thursday and Friday afternoons will be devoted to visits to scientific laboratories, Government institutions and various points of interest in and about Washington.

On Thursday evening the presidential address will be delivered and will be followed by a complimentary smoker.

Friday evening there will be a subscription banquet at the Shoreham, corner 15th and H streets N. W.

PERSONAL MENTION.

Mr. W. W. Wheatley, formerly with the Public Service Corporation of New Jersey, has been appointed general manager of the City of Mexico electric traction system and has already started for the scene of his new activities, with W. B. Rommel, an electrical expert.

Mr. B. H. Warren, second vice-president of the Westinghouse Electric & Manufacturing Company, has been elected president of the Allis-Chalmers Company, as successor to Charles Allis, who resigned the office a few days ago.

Mr. Robert McCulloch, general manager of the Chicago City Railway, has been elected vice-president and general managar of the St. Louis Transit Company, of which he became a director last week. It is probable that his son will be made superintendent, vice John Grant.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 8, 1904.

Electric Railways and Appliances.

753,839. Trolley-Wire Finder. William Barnhurst, Dallas, Tex. Filed June 1, 1903.

753,925. Electric Railway-Motor. Robert Siegfried, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed May 2, 1903.

753,929. Railway-Brake. Harry A. Spiller, Boston, Mass., assignor, by mesne assignments, to the Algonquin Electric Brake Corporation, same place. Filed May 6, 1903.

754,127. Switch for Overhead Trolley-Tracks. Walter L. Clark, Everett, Mass., assignor to J. Duncan & Co., Boston, Mass. Filed Dec. 24, 1903.

754,214. Traction-Wheel. William E. Harris, Pittsburg, Pa., assignor of one-half to Joseph F. Klapka, Allegheny, Pa. Filed July 18, 1903.

754,359. Apparatus for Stopping Railway-Trains from the Line and for Signaling Purposes. Bernardus A. J. van der Hegge-Zijnen, Hanover, Germany. Filed May 26, 1902.

754,362-754,363. Railway Signaling System. Henry Bezer, Westfield, N. J. Original application filed Oct. 19, 1901. Divided and last application filed Feb. 4, 1903.

Electric Lights and Appliances.

753,935. Incandescent Electric Lamp. Herbert M. Taylor, Hamilton, Can. Filed Sept. 2, 1902.

754,235. Extension-Fixture for Incandescent Electric Lamps. Conrad M. Pitel, Meriden, Conn. Filed May 6, 1903.

754,251. Electric Lamp. Charles P. Steinmetz, Schenectady, N. Y., assignor to the General Electric Company. Filed March 6, 1903.

Electrical Machinery and Apparatus.

753,866. Brush-Holder for Electrical Machines. William H. Foot, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 24, 1903.

753,872. Electric Printing-Machine. George S. Gallagher, New York City, assignor to himself, Rupert L. Joseph and Frank E. Burrows, same place. Filed April 29, 1903.

753,879. Electromagnet. Willis D. Gregory, Pittsburg, Pa. Filed April 9, 1903.

753,881. Electric Snap-Switch. Gerald W. Hart, West Hartford, Conn., assignor to the Hart Manufacturing Company, Hartford, Conn. Filed April 18, 1903.

753,954. Electric Machine. Niels A. Christensen, Milwaukee, Wis. Filed May 8, 1901.

754,123. Insulator-Pin. James H. Bullard, Springfield, Mass. Filed Oct. 26, 1903.

754,124. Electric Motor. David P. Burdon, Jacksonville, Fla., assignor of two-thirds to Samuel P. Holmes and Gustave Muller, same place. Filed July 13, 1903.

754,133. System of Alternating-Current Distribution. Edwin R. Gill, New York City, assignor to the Invention Developing Company. Filed Sept. 5, 1900.

754,291. Magnetic Clutch. Arthur C. Eastwood, Cleveland, O. Filed Jan. 26, 1904.

754,292. Elastic-Fluid Turbine. William L. R. Emmet, Schenectady, N.Y., assignor to the General Electric Company. Filed March 14, 1903.

754,371. Alternating-Current Transformation. Maurice Hutin and Maurice Leblanc, Paris, France, assignors, by mesne assignments, to George Westinghouse, Pittsburg, Pa. Filed April 3, 1895.

754,372. System of Alternating-Current Transformation. Maurice Hutin and Maurice Leblanc, Paris, France, assignors, by mesne assignments, to George Westinghouse, Pittsburg, Pa. Original application filed April 3, 1895. Divided and this application filed Nov. 19, 1903.

754,378-379-380. Electric Switch. Norman Marshall, Newton, Mass., assignor to the Marshall Sanders Company, Boston, Mass. Filed June 27, 1903, and Oct. 6, 1903.

Telephones and Telephone Apparatus.

753,903. Toll Apparatus for Telephone Exchanges. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company. Filed May 9, 1902.

753,927. Switching Apparatus for Telephone Exchanges. Edwin H. Smythe, Freeport, Ill., assignor to th Western Electric Company. Filed March 10, 1902.

753,956. Relay. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company. Filed April 1, 1901.

754,011. Commutator for Telephonic or other Circuits. Carl H. Prott, Rheydt, Germany. Filed June 14, 1902.

754,041. Telephone Attachment. Joseph Blum, Baltimore, Md. Filed May 23, 1903.

754,057. Antiseptic Attachment for Telephone Mouthpieces. William M. English and Arthur H. Ten Broeck, San Francisco, Cal. Filed April 1903.

754,211. Telephone or Telegraph System. Thomas W. Gleason, Boston, and Robert Hamilton, Milton, Mass. Filed May 1, 1903.

754,224. Telephone Repeater and System. Samuel P. Levenberg, New York City. Filed April 24, 1903.

Miscellaneous.

753,863. Wireless Signaling. Reginald A. Fessenden, Manteo, N. C., assignor to the National Electric Signaling Company, Pittsburg, Pa. Filed Sept. 28, 1901.

753,864-754,058. Signaling by Electromagnetic Waves. Reginald A. Fessenden, Fortress Monroe, Va., assignor, by direct and mesne assignments, to the National Electric Signaling Company, Pittsburg, Pa. Filed Oct. 1, 1903 and Aug. 8, 1903.

753,875. Electrical Manufacture of Iron Alloys. Gustave Gin, Paris, France. Filed July 7, 1902.

754,018. Electric Sad Iron. George J. Schneider, Detroit, Mich., assignor to the American Electrical Heater Company. Filed Aug. 11, 1903.

754,020. Electric Apparatus for Measuring and Recording Intervals of Time. Calvin J. Springer, Somerville, Mass. Filed June 27, 1903.

754,081. Battery Stopper. Albert Muller, New York City. Filed Oct. 24, 1903.

754,147. Apparatus for Electrical Production of Nitrogen or Other Compounds. Josef von Kowalski and Ignaz Moscicki, Freiburg, Switzerland. Filed Feb. 21, 1903.

754,152. Signaling Apparatus. Otto Luddeckens, Breslau, Germany. Filed Feb. 21, 1903.

754,208. Electric Signal. Joseph E. Feller, Brooklyn, N. Y. Filed April 24, 1902.

754,397. Electric Clock. George S. Tiffany, Brooklyn, N. Y., assignor of one-half to James Van Inwagen, Chicago, Ill. Filed Nov. 30, 1901.

754,402. Fault Locator for Electric Cables. Daniel E. Wiseman, Spokane, Wash. Filed Aug. 3, 1903.

THE TELEPHONE WORLD.

Another Independent Telephone Association Organized.

Representatives of Independent telephone lines of Southwest Missouri, Northwest Arkansas and Northeast Indian Territory lately met at Gravette, Ark., and organized the Tri-State Independent Telephone Association, with officers as follows; President, W. T. Stahl, of Siloam Springs; vice-president, S. H. Slaughter, of Fayetteville; secretary, K. J. Comfort, of Westville; treasurer, W. D. Wasson, of Gentry. The object of the association is the betterment of local and long-distance service. They will also endeavor to devise plans for farmers' lines in their respective territory. Their next meeting will be held at Fayetteville in June.

An application has been made for a charter for the Lake & Lehman Telephone Company. The object of those interested is to construct a telephone line for the accommodation of farmers residing between Dallas and Loyalville, Pa., and later to extend to Sweet Valley. The population of the torritory it is intended to serve is about 10,000, and 50 have already signified a desire to install telephones. Unless something unforeseen occurs the company will begin to place poles and string wires about the first of next month, the promoters being desirous of having the line in operation by June 1. The officers of the company are: President, C. H. Randall, of Loyalville; secretary, William Armstrong of the same place; treasurer, Milton L. Ruggles, of Pike's Creek.

For several months past Wolcott, N. Y., has been enjoying the benefits of a well-equipped telephone exchange without any cost to the patrons of the exchange. Some time ago the Empire Telephone Company established an exchange there with about 80 subscribers, with the understanding they should have its benefits three months free of cost. The time expired March 1, but as the company has recently been reorganized the telephone rates have not yet been fixed and the probabilities are that the free service will continue six or eight weeks longer. There is some prospect of an exchange being established by local parties in case the established rates of the present company should prove too high.

The Chickasaw-Choctaw Telephone Company of Durant, I. T., has purchased the franchise of the Bokchito Telephone Company, and will at once erect an exchange extending the long-distance line east to Bennington, Hugo and Antlers.

The telephone line from Whitesburg, Ky., to Stonega, Va., is nearing completion. When this is done it will put Letcher County in close connection with Louisville and other points in Kentucky.

A new telephone company is being organized at New York Mills, Minn., to establish an exchange in that village and extend lines into the country adjacent.

At the annual meeting of the stockholders of the New York & New Jersey Telephone Company lately the retiring board of directors was re-elected.

Texas Telephone Lines Under One Management.

E. H. Huntington has just closed a deal through Frank C. Smith, whereby he becomes owner of 13 additional Independent telephone exchanges in Texas. The new exchanges just purchased are the Austin, Taylor, Temple, Belton, Sour Lake, Saratoga, Kountz, Woodville, Village, Kirbyville, Coll, Jasper and Bronson, and the long-distance lines of the Commercial and the Lone Star Companies.

The price paid for these, together with the Houston, Galveston, Corsicana, Nacogdoches, San Marcos, Port Arthur and Liberty exchanges previously acquired, exceeds $1,000,000,

Many Rural Telephones in Kansas.

In the last six months more than 3,000 rural telephones have been installed in Kansas. The farmers in most cases organize a company, build their own line and charge each member the actual cost of the line and their part of the operating expense. In this manner it makes the telephone cheap. They connect with each other and also with the long-distance companies, making one large complete system. It is stated by good authority that more than 2,000 telephones will be installed next year.

The Home Telephone Company of South Bend, Ind., has decided to enter Niles, Mich., in competition with the Michigan Bell Telephone Company. The outlook is favorable for a cut-rate war. The newcomers will extend side lines to Buchanan, Galien, Three Oaks and Cassopolis, supplying service to intervening territory.

The Central Telephone Company of Nebraska, a concern organized to combine the Independent telephone companies of that State, has incorporated two new telephone exchanges, one at Loup and one at Ravenna. Articles of both exchanges were lately filed with the Secretary of State. Each exchange is capitalized at $25,000.

The new $100,000 switchboard of the Cuyahoga Telephone Company of Cleveland, O., has been completed and put in service. The board is equal to the one recently installed at Buffalo. In capacity, 36,000 subscribers, it is the largest board ever placed in service.

Attorney E. I. White has announced that the Syracuse, N. Y. Telephone Company has financed its bond issue made necessary by the contemplated reconstruction of its present system, and that the work will be taken up actively this spring.

The Warner Telephone Company of Buffalo, N. Y., capitalized at $50,000, has been organized with the following directors: T. S. Lane, Jamestown: A. S. Warner, Buffalo, and W. S. Lawton of Lawton.

Headquarters for the Pioneer Telephone Company, recently organized with a capital of $3,000,000. have been established in Oklahoma, Okla.

The United Telephone Company has greatly restricted its free radius in the vicinity of Chambersburg, Pa.

Independent Company Reorganized in Indianapolis, Ind.

At the annual meeting of the stockholders of the New Telephone Company, held last week, plans for the reorganization of the company were perfected. This step was made necessary, the officers say, by the rapid growth of the business and the great demand for the service, requiring large extensions in the way of cable and equipment. It has now in Indianapolis about 7,600 telephones, and connection with 1,000 in surrounding towns.

The plan for reorganization provides for the leasing of the present plant to a new company to be organized, which will be known as the Indianapolis Telephone Company.

The new company will be capitalized at $1,200,000 or $1,500,000, of which $400,000 will be in common stock, and the remainder in preferred stock.

Each stockholder of the present company will have the privilege of taking an equal amount of common stock in the new company, and in addition, will receive an amount of preferred stock.

The New Telephone Company was organized and incorporated on January 22, 1898. Its franchise is for 25 years and renewable for 25 years longer. The officers are S. P. Sheerin, president; Louis Hollweg, vice-president; H. B. Sale, secretary and treasurer. They will probably hold the same offices in the Indianapolis Telephone Company.

In a short time the two-story fireproof building for the Auburn, N. Y., Telephone Company will be completed. The building will be used exclusively for telephone purposes, the ground floor containing the offices of the company, public pay station booths, as well as a large store room. The second floor is given up entirely to the operating room, which will contain the automatic switchboards, distributing boards, ringing machines, etc., put out by the Automatic Electric Company of Chicago, as well as the toll board.

A local telephone company has been organized at Pelican Rapids, Minn., with a capital stock of $25,000. Work will be commenced as soon as the frost is out of the ground, the intention being to run lines into the surrounding country, where the farmers are ready to patronize it.

Nearly every subscriber of the United Telephone Company in Carlisle, Pa., has signed a petition agreeing to withdraw his 'phone April 1, unless the company rescinds its order to restrict the free radius in the county.

Telephone Incorporations.

The Conesville & Gilboa Telephone Company, Conesville, N. Y. Capital stock, $1,000. Incorporators: J. W. Gaylord, B. C. Wright and Elmer Baker.

The Treadwell Telephone Company, Treadwell, N. Y. Capital stock, $3,000. Incorporators: Robert B. Ballentine, Duane D. Wheat, Treadwell; V. R. Ogden, Leonta.

The Black Duck Electric & Telephone Company, Black Duck, Minn. Capital stock, $50,000.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alton, Ill.—The management of the Chicago & Alton Railway have decided upon electricity as the illumination for all of its passenger trains, and they will be so equipped as rapidly as possible.

Avoca, N. Y.—The subject of electric lights for this village is being agitated. President McCorn of the village of Hammondsport, accompanied by Philip Zimmer, Jr., has been here with a view of securing data on which to base estimates of the probable cost of an electric plant and the necessary accessories sufficient for lighting the streets of the village and for such public and private buildings as might require them.

Beaver, Utah.—It has been voted to issue bonds in the sum of $10,000 for the purpose of installing an electric light plant.

Chattanooga, Tenn.—The Chattanooga Plow Works will install an electric light plant and generate its own power.

Cheyenne, Wyo.—All bids for the electric lighting of the post were rejected, but will be readvertised for. Capt. W. S. Scott, quartermaster. Fort Russell, Wyo.

Clarion, Ia.—The Clarion electric light plant will be thoroughly overhauled and enlarged this spring and considerable new machinery put in.

Columbia, Tenn.—W. H. Corson states that a company contemplates installing an electric light plant here.

Concord, N. C.—It has been decided to put in electric lights here to cost $15,000.

Cottage Grove, Ore—The Cottage Grove Electric Company has purchased from W. H. Abrams the Cottage Grove electric light plant. The company intends to remove the present plant, and to install a complete new system.

Farmersville, Tex.—The Farmersville Mill & Light Company has been organized here with $50,000 capital to install an electric light and power plant, also a grain elevator. H. L. Carver and E. W. Stewart are interested.

Gilroy, Cal.—The council contemplates the installation of a dynamo in the gas works and electric lights for the streets of the town.

Grand Rapids, Mich.—James Cooper, superintendent of the Court House, has decided to advertise for bids for equipping the Kent County Home with a complete electric lighting plant.

Huron, O.—It is reported that a municipal electric light plant will be acquired by private interest.

Janesville, Wis.—This city may not buy a municipal electric lighting plant, as the bids received approximate $50,000, or $15,000 above the estimates.

Kirkwood, Ill.—A franchise has been granted to the Kirkwood Electric Company to operate an electric light and heating plant here.

Marshfield, Wis.—The city council purchased for $150,400 the electric light and waterworks, heretofore owned by the company of which former Gov. W. H. Upham is president.

Milford, Ill.—The Milford electric light plant has changed owners. E. Linder of Pecatonica, Ill., having purchased it from George Seaver.

New Haven, Ind.—Sealed proposals will be received by the trustees of this city until April 5 for the construction of a complete electric light system.

Onaway, Mich.—This village is to have a new electric light system.

Palenville, N. Y.—This town is soon to have electric lights.

Reading, Pa.—A special election will be held here to vote on the proposition to issue bonds to the amount of $200,000 for the erection and maintenance of a municipal electric lighting plant.

Ridge Farm, Ill.—The electric light plant here has been badly damaged by fire.

San Antonio, Tex.—Alex and Paul Meerscheidt are stated to contemplate installing an electric light and power plant on their irrigation farm near this city, where electric power would be used for pumping purposes.

Sebastopol, Cal.—G. W. Swain has asked for a franchise to erect and maintain an electric light and power system here.

Shreveport, La.—F. R. Hodges has asked for a franchise for gas, electric light and heating purposes. F. A. Trusten is on the council franchise committee.

Scottsburg, Ky.—The question of a new electric light plant is being considered here.

Terre Hill, Pa.—This city is agitating the question of electric lights.

Trenton, N. J.—The Indiana & Michigan Electric Company, capitalized at $2,000,000 was lately incorporated here to manufacture and furnish electric lights and power and to operate trolley lines. The incorporators are George W. Flaacke, Jr., H. Hobart Porter, Jr., and Francis Blossom, all of Jersey City.

Twin Valley, Minn.—This city is making another effort to secure an electric light plant. and this time it looks as if it would succeed.

Vincennes, Ind.—The E. M. Dean Syndicate of Grand Rapids, Mich., has purchased the citizens' gas plant and the Vincennes electric light and power plant, and will spend $50,000 in improvements.

Whiting, Ind.—The Lake County Light & Power Company has been incorporated with $100,000 copital, and will build an electric light and power plant here. R. J. Cary and S. T. Chase are interested.

Wilson, N. Y.—A company with a capital stock of $3,000 will build an electric plant to furnish the residents with street and house lighting, and also for power purposes. A. F. Bowker, F. H. Tower and E. Tower, of this place, are interested in the movement.

STREET RAILWAYS.

Bath, N. Y.—John Tuerk, of New York City, has applied for a franchise to construct and operate an electric railroad here.

Danville, Ky.—Dr. M. Crow, of Versailles, will soon lay before the city council a proposition concerning the construction of an electric road between this city and Junction City.

Elizabethtown, Ky.—An electric railroad from Buffalo to this city will shortly be built. The capital is in sight, and an engineer will probably be employed at once to make the survey.

Iowa City, Ia.—An electric street railway system will be installed here by the Iowa City, Davenport & Muscatine Electric Railway Company.

Jamestown, N. Y.—A certificate of merger of the Warren & Jamestown Electric Railway Company with the Warren & Jamestown Electric Street Railway Company, has been filed at Albany with the Secretary of State.

Monroe, Mich.—Peter Jacobson, who promoted the Detroit & Monroe Electric Railway, is endeavoring to secure another electric railway from here to Dundee.

Nahant, Mass.—The Nahant Street Railway Company has been granted a franchise to build an electric road between this place and Lynn.

Napoleon, O.—The Lake Erie, Bowling Green & Napoleon Electric Railway Company has issued and sold $1,000,000 5 per cent. 30-year gold bonds, the money to be used to extend the present line to Fort Trenton and this city.

Richmond, Va.—The corporation commission has issued a charter to the Seaboard Traction Company, composed principally of Norfolk capitalists, to operate an electric passenger and freight line, 300 miles long, between this city and Portsmouth and through the principal truck and peanut section of the State. The capital stock is fixed at $250,000 minimum and $800,000 maximum.

Valparaiso, Ind.—The Northern Traction Company proposes to build a road from South Bend to Hammond.

Warrensburg, N. Y.—The Delaware & Hudson Railroad Company is said to be backing a proposed extension of the Hudson Valley Electric Railway through the Adirondacks from here to Elizabethtown. Charles S. Taylor is interested.

Warsaw, Ind.—The estimated cost of building the Goshen-Warsaw electric line is $600,000.

Woodland, Cal.—N. A. Hawkins has secured a franchise for an electrical railroad through the central part of Yolo County in the vicinity of this city.

York, Pa.—The York County Traction Company will soon consider the proposition to increase its capitalization from $1,500,000 to $5,000,000.

POWER PLANTS.

Spokane, Wash.—It is proposed to develop power on the Spokane River, 25 miles from this city, where a flume will be constructed to supply a 33-foot fall. Electricity is to be furnished this city and other points. David Wilson is interested,

Syracuse, N. Y.—An effort is being made to interest local capitalists in the plan to develop electric power from Northern New York streams for transmission to this city and elsewhere in Central New York. Assemblyman Merritt of St. Lawrence County has introduced a measure into the Legislature at this session to give any such company the right to condemn property for a right of way for high tension wires for the transmission of the power.

Quebec, Can.—Another electric company is likely to be formed shortly under the name of the Quebec Electric Company, several local men being interested in the new concern. The plan is to install a hydraulic electric plant at Seven Falls on the River of St. Anne in Montmorency County.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅜@12⅝c.; Lake 12½@12¾c.; casting, 12⅜@12⅝c.

Otis Elevator dividends are payable April 15. Books close March 30 and reopen April 16.

According to Electric of America interests, earnings since the first of the year have equalled those for the corresponding period of 1903.

The Union Traction Company of Indiana has declared a dividend of 2½ per cent. on its preferred stock, payable April 1 as registered March 21.

At the annual meeting of the stockholders of the United Electric Company of New Jersey, held in Newark, the number of directors was reduced from 21 to 8.

The Cumberland Telephone & Telegraph Company will pay the regular quarterly dividend of 1¾ per cent. on April 1. Books close March 20.

The recent heavy selling in the Metropolitan Street Railway issues in New York was attributed to James R. Keene, who was said to be liquidating holdings of the late W. C. Whitney.

It is reported from Pittsburg that the Philadelphia Company has bid $2,000,000 for the Murray Verner Traction Company franchise and that the owners are holding out for $2,500,000.

The Indiana & Michigan Electric Company capitalized at $2,000,000, has been incorporated in Trenton, N. J., to manufacture and furnish electric lights and power and to operate trolley lines.

The executive committee of the General Electric Company will meet next week to take action on the common dividend, which will be paid April 15. The usual rate of 2 per cent. quarterly is expected.

The Committee on Railroads of the New York Board of Aldermen will give a public hearing at City Hall at 3 P. M. on March 18 on the petition of the Union Railway Company for the grant of a franchise to construct and operate a street surface railway in the City of New York.

The creditors of the Michigan Electric Company, after hearing a report from the committee appointed to appraise the assets, have decided to authorize the sale of the assets and business by the Union Trust Company as receiver, with the co-operation and advice of the committee.

A meeting of the stockholders of the Springfield Railway and Light Company will be held on March 17 at the office of the company, 419 Market street, Camden, N. J., for the purpose of electing a board of seven directors to serve for the ensuing year and to transact such other business as may be brought up for consideration.

The National Carbon Company, it is reported, will spend $200,000 during the present year in the construction of a new plant to meet the development of its business. It will not be located in Cleveland, but at some other point, not yet named, where it will be nearer the source of the business handled. It is understood that it will probably be at Chicago.

New York Traction stocks fared badly in Wall street on Saturday. Metropolitan lost 4⅛ points, Metropolitan Securities 8 points to 75, and Third Avenue 2½ points to 117½. In some quarters the selling was explained on the score of the addition of the Elsberg bill to the bill of the Rapid Transit Commission. The bill, it was said, would defeat the entire measure and prevent the further construction of subways.

EDITORIAL NOTES.

"Union Home for You All." Mr. Andrew Carnegie sailed for Europe on Saturday, but before his departure he settled the question about erecting the engineering building, doubt about which had arisen on account of the refusal of the Civil Engineers to unite with the other engineering societies in accepting Mr. Carnegie's offer. He not only stands by his original proposition, but also adds the half million dollars which was to go for the sole benefit of the Civil Engineers, as will be seen by the following letter:

"Gentlemen of the Mechanical Engineers, Institute of Mining Engineers, Institute of Electrical Engineers, Engineers' Club of New York: It will give me great pleasure to devote, say, one and a half million of dollars for the erection of a suitable Union Home for you all in New York city. With best wishes, truly yours, Andrew Carnegie."

Prompt and energetic work is now being done by the men selected to represent the above-named societies. Saturday afternoon the Building Committee met at the Engineers' Club and reorganized, subdividing the work of plan and scope and erection of new buildings. The American Society of Mechanical Engineers was represented by J. M. Dodge of Philadelphia, C. W. Hunt and Prof. F. R. Hutton of this city, and Colonel Muir. The American Institute of Mining Engineers was represented by A. R. Ledoux, Charles Kirchoff and Theodore Dwight of this city. The American Institute of Electrical Engineers was represented by C. F. Scott of Pittsburg, B. J. Arnold of Chicago, and S. S. Wheeler of this city. The Engineers' Club was represented by John C. H. Kafer, W. H. Fletcher and T. Commerford Martin.

The reorganized General Committee is composed of Charles F. Scott, chairman; A. R. Ledoux, vice chairman; John C. Kafer, treasurer, and Prof. F. R. Hutton, secretary.

* * *

A Bell Company's Poor Service. Elsewhere in this issue will be found the continuation of an excellent article on the Independent telephone movement by Mr. J. B. Ware. The people of the middle West are not the only ones that are dissatisfied with the Bell service. As the author of the paper already referred to states, however, in the East the Bell monopoly has to a great extent controlled the Legislatures and thereby kept out competition. In this connection it is interesting to note that as a result of the continued unsatisfactory service which is being rendered to the patrons of the telephone by the Chesapeake & Potomac Telephone Company in the District of Columbia there has been introduced a bill before Congress for the purpose of granting a charter to a new company, to be known as the District Telephone Company, which is to render service to its patrons at a cost not exceeding $36 per year for private residence 'phones and $48 for public offices. The capital of the new company would include $1,000,000 and a bonded issue of stock to a like amount, the books for the subscription to same to be opened up in the District, and not less than 10 per cent. of all stock taken would have to be paid up to commence. It is also provided that the District should be authorized to give the necessary permits for the construction of conduits, etc. With the present state of strained feelings existing in the District, and the pressure that is being brought to bear on Congress as a consequence, it would not be at all surprising if the bill should be passed.

Will Require Large Capital.

Since the recent announcement in ELECTRICITY of the proposed combination of the Bullock Electric Company and the Allis-Chalmers Company there have been many changes in the official staff of the latter company, and already there is considerable speculation about what effect the new "combine" will create in the electrical trade. It is claimed among electrical experts that it will require from $12,000,000 to $14,000,000 of new capital and the energy of a great force of skilled mechanics to make successful the electrical combination proposed.

The invasion of the Corliss and gas engine field by the Westinghouse and General Electric Companies is believed to have induced the proposed combination on the part of the Milwaukee engine builders.

It is estimated, however, that the manufacture of electrical machinery, as heavy as that made by the General Electric and Westinghouse Companies, and to correspond to the heavy engines now built at Milwaukee, will require at least $1,000,000 for patent rights and designs, fully $500,000 for new patterns and $2,000,000 more for new equipment and tools. In addition it will require $3,500,000 of new working capital and $4,000,000 for material entering into electrical machines that will require two years to build. It will also require a long time to gather together a sufficient force of electrical engineers to make successful the invasion of the electrical field.

It is pointed out that the General Electric and Westinghouse Companies have been able to save immense sums of money by reason of their alliance in respect to patents and that litigation on patents might form a costly item in any new venture in the field now held between these two companies.

* * *

Continuous vs. Induction Motors.

Mr. H. M. Hobart, whose name has become quite a household word among English and Continental electrical students because of his valuable contributions to the scientific societies and the electro-technical press on matters relating to the design of motors and dynamos, discussed the rated speed of electric motors as affecting the type to be employed before the London Institution of Electrical Engineers on March 10. For the continuous current motor, he remarked, high speed is an unfavorable condition, but up to certain limits such speed conduces to improved results for induction motors. It is true that the required speed can rarely be the determining factor in the choice between these two classes of motors, but Mr. Hobart, with a view to emphasizing the extent of the influence of speed selected a set of continuous current designs and two sets of induction motors, and by means of curves roughly indicated the relative factory costs of eleven designs in these three groups. The continuous current designs were for a 150 hp. shunt motor, and the five speeds ranged from 68 r.p.m. to 1,224 r.p.m. In regard to the induction motors, the first group was for 21 cycle motors ranging from 36 poles and 68 r.p.m. to 4 poles and 612 r.p.m., and the second group was for 63 cycle motors ranging from 12 poles and 612 r.p.m. to 6 poles and 1,224 r.p.m. He found that for motors having equal rotor dimensions the continuous current motor could be taken as costing 50 per cent. more than the induction motor, but this would not represent the ratio of cost for the same output, because different diameters and lengths would be taken in the two cases. It appeared from the curves that with increasing speed, while all the properties of the induction motor improved markedly, the reverse was the case for the continuous current motor. This result might be considered to point out the best field for the respective types, and that the influence of the speed should be taken into account when other circumstances permit.

The main conclusions which were set forth as the result of Mr. Hobart's investigations are not new, but it is held that they must be much more widely understood if the electrical transmission of power is to proceed on rational lines. They are as follows: (1) Induction motors are, for all capacities, considerably cheaper than continuous current motors of equivalent ratings. (2) The general performance and the mechanical construction of induction motors improve rapidly with increasing rated speeds. (3) The general performance and the mechanical construction of continuous current motors improve rapidly with decreasing rated speeds. (4) The use of very low-speed induction motors and very high-speed continuous current motors ought to be avoided whenever this is commercially practicable.

With a flourish of trumpets to the outside world, the city authorities of Holyoke, Mass., organized a municipal lighting plant and it now appears that it is not to be the success that was predicted. One of the net results is a cost of $153 to the city for street lights which the company had previously agreed to furnish for $75. The profit of $7,159 in the year's business is in effect a deficit because of the loss from taxes formerly levied on the concern when owned by private capital.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Conptroller Grout introduced a resolution, which was adopted, at the Rapid Transit Commission Friday, providing for the operation by the city of New York, of subway lines, if approved by vote of the people.

For the purpose of studying mining, scientific and industrial enterprises in this country a commission composed of four Frenchmen, an Italian, a Belgian and a Swiss arrived in New York Saturday on the Savoie, of the French line. The members will spend about two months in the United States, visiting not only the leading mining and industrial centers, but taking in many other points of interest. In charge of the party is Prof. Geogg, who holds the chair of industry in the High School of Commerce in Geneva.

Muskrats by burrowing through the embankment of Mohawk Lake, from which power was obtained for the electric light plant at Brantford, Ont., caused the water to flood vacant fields instead of flowing to the plant, entailing a loss of $5,000 to the company.

A fine collection of telephone curios has been secured by B. F. Wasson, who has charge of the exhibit which will represent the evolution of the Independent telephone at the World's Fair at St. Louis.

The office of the Western Union Company in Augusta. Ga., will accept messages for transmission to a number of the ocean liners which have been provided with Marconi apparatus. The rate is $2.50 for ten words, and 15 cents additional for every word over ten.

Two interesting papers, one by C. Renshaw on "Present Electrical Railway Practice" and the other on "Adaptation of Alternating Currents to Railway Purposes," by P. M. Lincoln, were read before the Engineers' Society of Western Pennsylvania in Pittsburg at its meeting last week. The subject for discussion was the traction car with its electric power, and the means of application and operation of electricity in that field was discussed in detail.

POLE LINE WORK IN MANILA.

Some time ago there appeared an article in ELECTRICITY (November 18, 1903) descriptive of the various types of telegraph and electric light poles made use of in Manila, Philippines. The correspondent of ELECTRICITY in that locality recently forwarded a number of photographs of the poles themselves, which

Pole Line Construction in Manila, Philippines.

appear in this issue. As will be seen the poles are of wood, frequently spliced together to make them the desired height. It might be added that the poles now in use are a great improvement over the light bamboo poles erected by the Spaniards.

PRESENT INDEPENDENT TELEPHONE SITUATION.*

BY J. B. WARE.

(*Concluded from page 150.*)

In a large portion of the State of Illinois, the same general results have been attained, as in a majority of the States already mentioned. In Chicago, the Illinois Telephone & Telegraph Company (the Automatic) has its tunnels completed, 40 feet below the streets, and under the most important business sections of the city. There are over 22 miles of these tunnels at the present time. This company has already constructed one exchange on the corner of Fifth avenue and Monroe streets, which has 4,000 automatic telephones in service. It is expected this company will have over 20,000 telephones working in Chicago within the coming twelve months. The plan has been announced to construct long distance lines from Chicago to the connecting lines of the other Independent companies. Actual work on this development is to begin in the spring.

In Wisconsin, the Independents are rapidly growing, and have over 35,000 telephones, which number is greater than the Bell telephones in the State, outside the city of Milwaukee.

Iowa is the home of many companies, there being over 1,200 Independent companies in that State, with many more telephones than has the Bell. The long distance lines are now receiving more than usual attention, and the people of Iowa will soon have adequate exchange and toll line facilities.

Missouri is also ours. St. Louis, with its more than 12,000 'phones, exceed in number those of the Bell; Kansas City's new exchange has just opened, built for 12,000 subscribers, and it has every prospect of driving the Bell to the wall. St. Joseph, Jefferson City, Hannibal, Joplin, Springfield, Clinton, in fact, all the cities of the State have Independent exchanges; and it is estimated that there are twice as many Independents as there are Bell telephones in Missouri. Excellent long distance lines are being constructed, and the future is assuredly favorable *only* to the Independents.

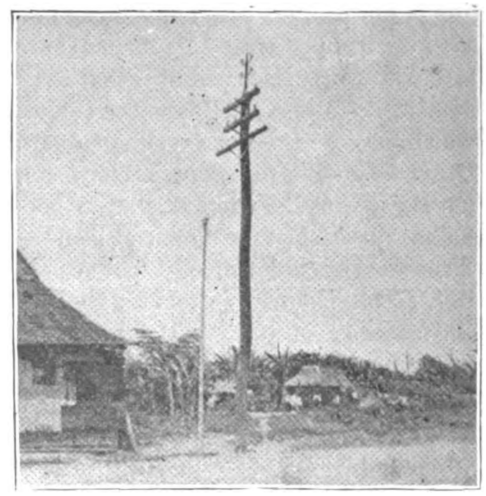
In Kansas, the number of Independent telephones exceeds 50,000, while the number of the Bell is less than 9,000. In Oklahoma, a condition very similar to that in Kansas prevails. The long distance system connecting Missouri, Kansas and Oklahoma are about completed, and as a rule, are of better construction than are the lines in many of these sections.

In Nebraska, the Dakotas, and other Western States, the movement is well established and steadily growing.

In the Coast States of the extreme West—California, Oregon and Washington—a very remarkable development has taken place during the past two years. Thus, Southern California has been completely developed by the Independents. In Los Angeles they have 12,000 telephones in service and are growing at a tremendous rate. In Portland, Ore., and in Seattle, Wash., fine exchanges have been recently completed.

The indications are that California, the heretofore famous stronghold of the Bell interests, will within a very short time pass into the control of the Independents, and thus be forever freed from the Bell domination, with its high rates and low quality of service.

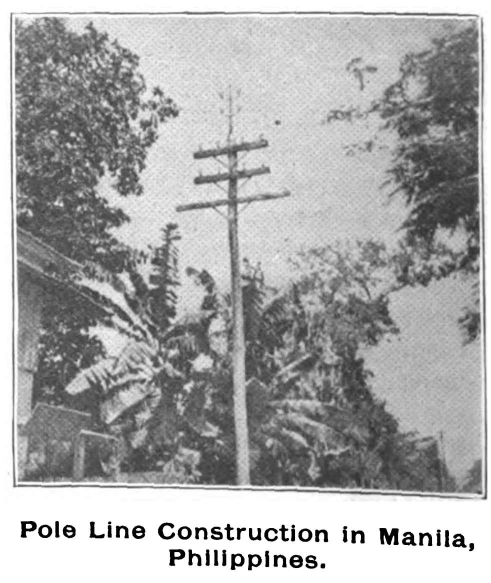
I have not as yet, nor will I, take up in detail the very gratifying situation in Michigan, as you are familiar with the same. We have about 50,000 telephones in the State, as against the 51,000 claimed by the Bell. If Detroit and that portion of the other cities "sold" four years ago, and which as yet have not been redeemed, are omitted, we have over 20,000 more telephones in service than has the Bell Company.



Pole Line Construction in Manila, Philippines.

As the result of the 25 years' history of the Bell movement it has less than 1,500,000 telephones now in use by its exchange subscribers in the United States. The result of the eight years of the Independent movement shows 2,000,000 telephones in service. Of the 180 cities having over 25,000 inhabitants, according to the last census, 70 per cent now have independent exchanges in operation.

In conclusion, I wish briefly to refer to the very satisfactory financial success, as a whole, of this movement. Few in-



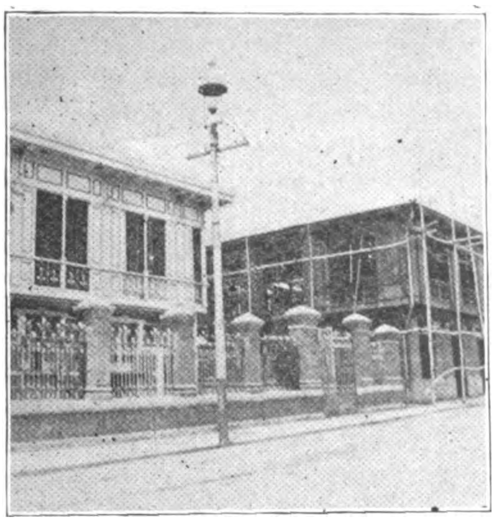
Pole Line Construction in Manila, Philippines.

deed, have been the number of failures among the more than 6,500 Independent companies. The Bell company has compiled and is widely advertising its record of these failures, which number less than

*Paper read at the annual convention of the Michigan Independent Telephone Association held in Detroit, Feb. 25, 1904.

a score—not one of which occurred in our own State.

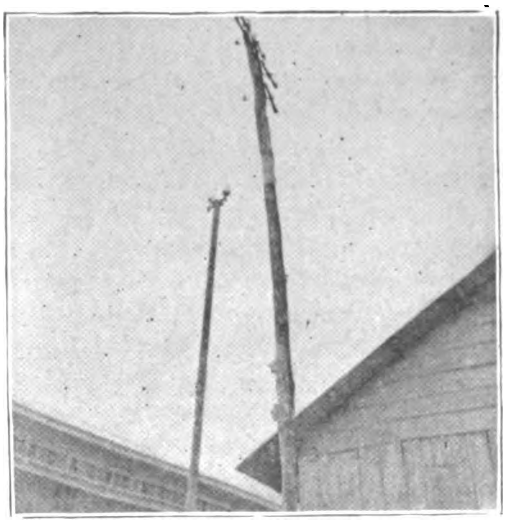
The cities of Boston, New York, Washington, New Orleans, Cincinnati, Chicago, Milwaukee and San Francisco, are the only cities having more than 200,000 population, in which telephone competition is not established; and Chicago must soon be dropped from this list as heretofore shown. Each of the cities just named has a local Bell licensee company, which is at present very prosperous. Other licensee Bell companies have ceased paying dividends, and are understood to be in unsatisfactory financial condition. Even the parent company (the American Tel. & Tel. Company), owning as it does the majority of the stock in each of its many licensee, or Bell Companies, and dependent for its financial success upon the royalties which said companies pay on each telephone used, has apparently been seriously affected by the Independent competition, as indicated in part by the



Pole Line Construction in Manila, Philippines.

falling off in price of its stock from 167 in April 1902, to 117 in October, 1903, its present price ranging about 122.

The various licensee or operating companies of the American Bell were capitalized years ago, and before competition existed, resulting in over-capitalization under present conditions. It seems certain that these companies cannot continue to pay interest on their securities, and also the royalties to the American Tel. & Tel. Company The policy of the American Tel. & Tel. Company may possibly be foreshadowed as to its subordinate companies in the recent failure, foreclosure sale and reorganization of the Michigan Telephone Company, in which it held over 70 per cent. of the capital stock. Its property was sold by the Union Trust Company of Detroit, as receiver, the sale realizing about 80 per cent. of the mortgage foreclosed. The stockholders (some 743) lost all, being $1,312,700. The American Tel. & Tel. Company owned $3,687,300 of said stock, which was cut



Pole Line Construction in Manila, Philippines.

off by said foreclosure sale, as was also an indebtedness owing by the Michigan Company to the American Tel. & Tel. Company and its subordinate companies, amounting to over $2,500,000. It would thus appear that the American Tel. & Tel. Company loses over $6,000,000 by this failure.

It is possible that some secret arrangement exists by which the parent company secures in the reorganization of the Michigan Company some compensation not apparent to the public. It is possible that the parent company expects by the reorganization plan to secure the payment of its royalties which is absolutely essential to the American Tel. & Tel. Company's existence. It is an interesting and grave question, however, whether there exists any rational solution to the desperate financial problem now confronting every Bell organization—whether there is yet one chance to save permanently valuable telephone property, which, through a wrong policy and mismanagement under same, has been brought to the very verge of a financial precipice which is as surely destructive as is the great Niagara to unfortunates once engulfed.

The failure of the Michigan Bell Company, as stated, involves more property, and a loss to stockholders many times greater than the aggregate value of property and losses involved in all Independent telephone failures during the past seven years of their existence.

In the United States there are 4,700 national banks, and 1,078 savings banks (World's Almanac, 1904), making a total of 5,778 such banks. It is claimed, and I believe properly so, that the number of these bank failures, during each of the past five years, have exceeded the number of telephone companies (both Bell and Independent) that have failed during that entire period. No other class of business can make such a splendid showing, and no other business is of greater permanency or in greater demand in both the commercial and social world.

That the future appears to have an abundance of success and comfort to the Independents, none will deny, who are both posted and honest. That the same future appears to have very much of disaster and sorrow to the many Bell interests seems assured. Knowing their ability to furnish the very best quality of telephone service and at the lowest reasonable rates, and knowing that they have the confidence of the people, the Independent companies will go on to that assured success to which they are entitled by reason of their past efforts and their past accomplishments.

DASH POTS FOR CORLISS ENGINES.

ARTICLE IV.

BY W. H. WAKEMAN.

Working engineers who have given the theoretical part of their business little attention, find it difficult to read a drawing or understand a cut. The ability to do this can be acquired by every man in charge of a steam plant, although it takes some much longer than others. It is a good idea to begin the study by taking plainly made illustrations which relate to simple devices, such as are illustrated in this series of articles.

Sometimes an engineer will take up a paper, and if he happens to see something that he does not understand, he may throw it down and give it no further attention. This is certainly a mistake, for mechanical papers are published for the purpose of explaining things that their readers do not fully understand, thus enabling them to do better work because their efforts are more intelligently directed.

For an application of this advice, take Fig. 8 which illustrates a simple form of dash pot. In this case the pin which passes through the ears, 2 and 3, is shown at 4, but the rod is omitted. However it fits in between these ears and the pin, 4, passes through it, being a sliding fit at this point.

The plunger is now in its lowest position, but when raised a partial vacuum is

formed under it in the chamber, 5. The plunger is fitted with three packing rings as shown, to assist in keeping it air tight. No means are provided for letting air out of this chamber.

In order to understand the cushioning device, suppose that the dash pot plunger is raised to its highest position, and has just begun to descend.

The outer part of it (shown at 6) is now up far enough to let air circulate under it freely, but as it descends the tendency is to confine this air in the chamber 7. It will be noted that at the lower part of 6 the bore is enlarged. The object of this design is to gradually confine the air and avoid a sudden closure of the passage through which it escapes. This results in bringing the plunger to rest without shock

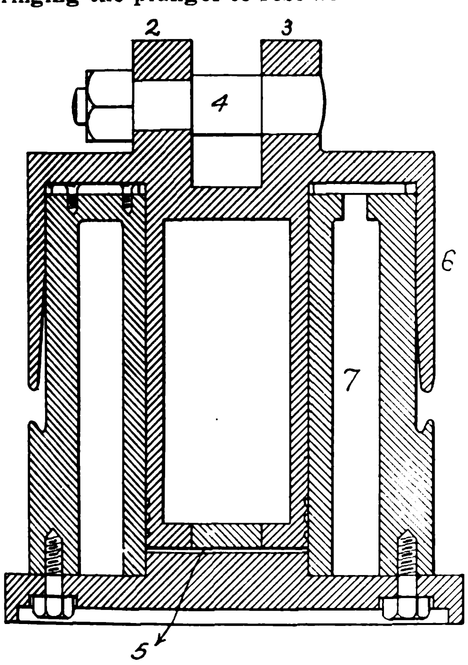


FIG. 8.

or jar. The amount of cushion cannot be regulated, as the manufacturers seem to think that the device is perfect when it leaves their hands, and that it will always remain so.

The dash pot shown in Fig. 9 is a trifle more complicated in design but its operation will be easily understood from the following description.

The upper part of plunger, 2, is smaller in diameter than the lower, therefore as it moves the amount of air displaced is not the same in both cases, and this difference is further increased by the design of other parts. Special attention is called to this point, because it is the main principle on which the operation depends.

In the cut the plunger is ascending and is now about midway of its travel; 3 is a chamber under the larger part of it, and 4 is another chamber which extends entirely around the plunger. It is formed by reducing the diameter of the upper part as shown. These two chambers are connected by the passage, 5, therefore as the plunger ascends the chamber, 3, is enlarged several times faster than 4 is diminished, making a strong downward

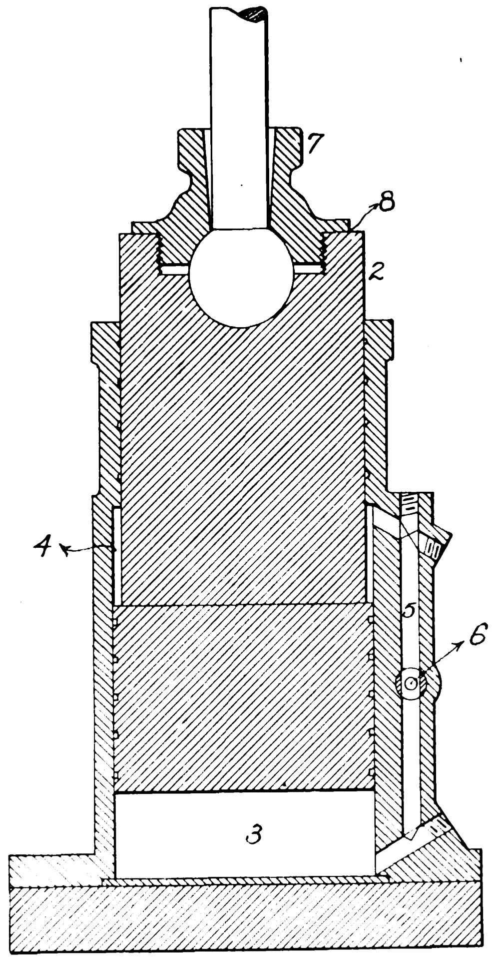

FIG. 9.

draft of air through 5, or to use an expression common among engineers, it creates a strong suction at this point, removing about all of the air from 4 and at the same time creating a partial vacuum in 3.

From the above description and explanations preceding it, of the action of air in dash pots, it will be seen that when the plunger has reached its highest point, and the valve crank is disengaged from the wrist plate connection, the cut-off valve will be closed very quickly.

Let us suppose that the plunger is next raised as high as it can go and follow its operation downward. At first the effect of a partial vacuum in 3 is very strong, and here is where it is needed most.

As it begins to descend the air pressure in 3 is increased, forcing it up through the passage 5 into 4, but it cannot travel fast enough to entirely relieve 3, neither is there room enough for it in 4, therefore the plunger comes to rest gradually.

A peculiar feature of this dash pot is found in the fact that no air is discharged from it, as with those already illustrated, but the same air is kept in circulation. A valve is located at 6, which may be used to obstruct the passage 5 and thus regulate the whole operation.

Nine packing rings are used to prevent the escape of air around the upper and lower parts of the plunger, as shown in the cut.

The rod is connected to the plunger by a ball and socket joint, which allows it to swing in any direction. Lost motion at this point is taken up by unscrewing the nut, 7, putting it in a lathe and removing some of the iron at 8. Care must be exercised not to remove enough to make the nut clamp the ball.

Dash pots are designed so that when they are lifted to their limit the greater force is brought to bear to bring them down, and this is proper, because it is needed at this time. One reason for this is found in the fact that when a cut-off valve is opened wider than usual it does not close so easily, as new wearing surfaces are brought into contact with each other. On general principles, the wider a valve is opened the more force it requires to close it.

THE RIEDLER-STUMPF STEAM TURBINES.*

BY WALTER RAPPAPORT.

The heat energy of steam can be thoroughly utilized in steam turbines in different manners. First, the steam can be allowed to expand in conical nozzles, and then the kinetic energy be turned to account. The first steam turbine which utilized the steam in this way was the de Laval turbine. But theory proves to us that in such purely action turbines the circumferential velocity must be equal to half the steam velocity, which with the present customary pressure of at least 140 lbs. per square inch, amounts to about 3,600 feet per second, in reality even somewhat greater, as the angles of the vanes at the points of entrance and exit are not zero. In the de Laval turbine this would, therefore, necessitate a circumferential velocity of 2,000 feet per second, a moving wheel of about 20 inches diameter, making 30,000 revolutions per minute. These figures are practically not applicable, and so de Laval was forced to gear down this high rotary motion of the wheel, whereby, of course, the economy was greatly diminished.

A one-wheel purely reaction turbine is out of the question, for the reason that here the circumferential velocity must be equal to the steam. velocity, the number of revolutions, therefore, being twice as many as in the de Laval turbine. Parsons made use of the pressure in different

*From the "Electrical Review," London.

stages, and in this way achieved satisfactory results, although the number of revolutions cannot be decreased *ad libitum*, as the application of a great number of stages would increase the internal friction greatly and make the machine extremely complicated. The latter drawback was removed by Rateau, who used but few stages, but let each wheel rotate in a closed chamber.

A third means of reducing the number of revolutions is by charging the steam with specifically heavier gases, as has been attempted by Escher, Wyss & Co. in Zurich. These trials were, however, unsuccessful, as it was impossible to completely regain the mercury vapors which were employed.

Recently Profs. Riedler and Stumpf have published turbine constructions which aim at reducing the number of revolutions as much as possible with economical utilization of steam. First, they constructed wheels on the de Laval principle, but increased the diameter of the wheel considerably, up to 6.5—7.7 feet diameter, so that the necessary circumferential velocity

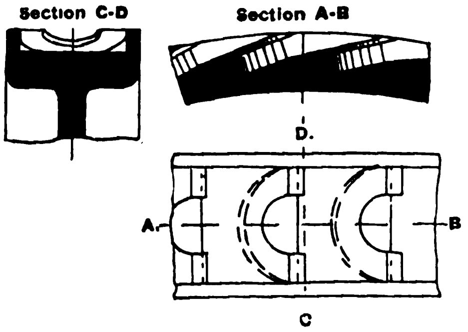

FIG. 1.
Blades of a Riedler-Stumpf Turbine.

was attained without having to reckon with an enormous—practically impossible—number of revolutions. The wheels are constructed as massive nickel steel disks, the factor of safety being five. The wheels are balanced very exactly so that the center of gravity is precisely in the center of rotation. The bearings are contrary to those in the de Laval turbine, placed quite near the disk, and the blades not inserted singly, but milled like pockets in the rim of the wheel as shown in Fig. 1. The pockets may also be constructed in pairs, and then are similar in form to the buckets of a Pelton wheel. Whereas de Laval employs at the most eight nozzles with elliptical outlet section placed singly, the Riedler Stumpf construction has nozzles of rectangular section close to one another on the whole circumference of the moving wheel, so that the string acts in a broad ring. The play between the stationary and moving parts can thereby be ⅛ inch — 1/12 inch, contrary to the Parsons construction. A turbine of the aforesaid construction of about 2,000 hp. capacity is set up and working in the Moabit electric supply station of the Allgemeine Elektricitats-Gesellschaft. The steam pressure is 200 lbs. per square inch

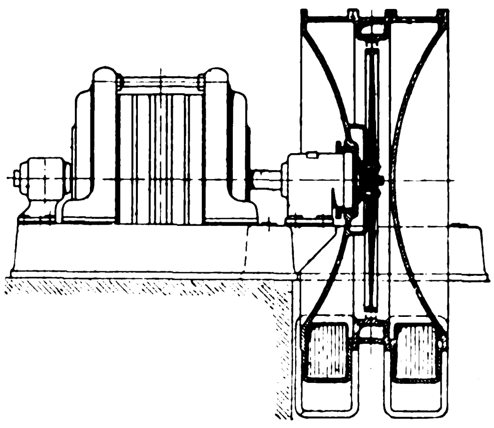

FIG. 2.
Riedler-Stumpf Turbine of 2,000 Kw. Capacity.

absolute, at a temperature of 294 degrees C., and the vacuum in the condenser is only 85 per cent. The wheel of this turbine weighs only 850 kg., and is direct coupled on the overhang of the heavy dynamo shaft, so that a simpler turbine can scarcely be imagined, and the mechanical efficiency amounts to nearly 100 per cent. Fig. 2 shows this turbine.

Instead of using the kinetic energy of the steam in one row of blades, it can be utilized in several wheels in succession. Only a part of the energy is used for the first wheel, this being easily achieved by suitably dimensioning the angles of the veins at the points of inlet and outlet,

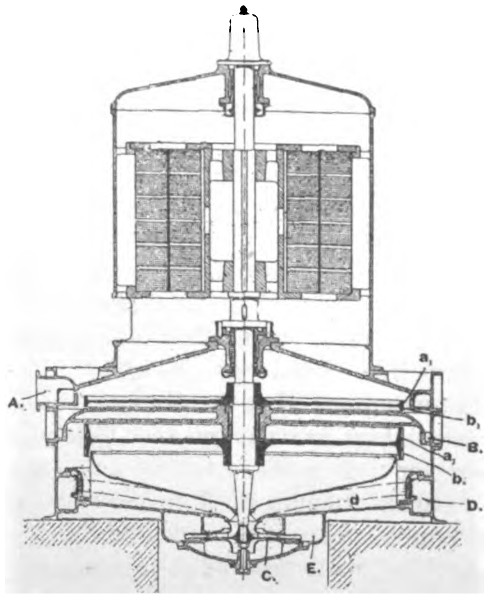

FIG. 3.
2,000 Kw Riedler-Stumpf Turbo-Generator.

guiding over the steam to a second moving wheel, where it again loses a part of its energy, and then, if desired, to a third and fourth wheel. Too many velocity stages would injure the economy of the turbine, as the friction of the steam would then become too great. There are two methods of construction to carry out this principle; the steam is either carried from the expansion nozzles over the first moving wheel, and from here by reversing guide blades back again to the same vanes, or the steam may be carried to a second wheel. The first construction is naturally the simpler and cheaper, but it only allows the steam to act on a part of the circumference. The second has the additional advantage of permitting the construction of the blades of both wheels with different angles, according to the steam velocity at these points. This type of turbine has already been built in sizes from 20—500 kw. by the A.E.G. The smaller constructions are well adapted to be placed on the boiler of a locomotive, where, in connection with a generator, they serve to illuminate the train.

A third turbine construction, having great resemblance to that of the American Curtis, has at the same time pressure and velocity staging. The steam expands in nozzles to a certain degree and then transmits its kinetic energy to diverse wheels in succession, it then comes to a second system of nozzles, expands there still more, and gains further velocity, etc., till its pressure has dropped down to the atmosphere or condenser pressure, and it has lost all velocity. The construction of the turbo-generator is shown in Fig. 3. At A the steam enters into the first nozzles and then impinges upon the moving blades a_1 and b_1. In this first pressure stage double velocity staging is applied. From b_1 the steam goes to the second nozzle system, B, the pressure drops down to the condenser pressure and the steam acts on a_2 and b_2. In all there are two pressure stages, each having double velocity stages used in the machine shown in Fig. 3, which possesses a capacity of 2,000 kw.

A special feature of the Reidler-Stumpf turbines is the attaching of centrifugal jet-condensers to the turbine shaft itself. Such an apparatus is shown at C in Fig. 3. The steam enters through the annular channel, d, from the last moving wheel to the condenser wheel and mixes with the cold water coming in through pipe D. The mixture flows off through pipe E. Such an arrangement is, of course, not only possible with vertical, but also with horizontal construction, where, for instance, the turbine is overhanging attached to the one end of the dynamo shaft and the condenser wheel to the other one.

Another proposition has been made, to omit the reversing guide blades for velocity staging and to replace them by wheels rotating in the contrary direction.

The steam would, therefore, first expand in a nozzle, then lose a part of its velocity in revolving the first wheel, and act on a wheel running in the contrary direction, then again act on a third wheel running parallel to the first one, and so on. The advantage would be that the steam would act on several wheels with less friction and in unchanging direction. In the construction, however, according to this principle, the admission and exhaust of the steam would involve difficulties.

Prof. Riedler in his paper read at the Berlin meeting of the Schiffbautechnische Gesellschaft (Society of Naval Engineers) gave some figures on the economy of his turbines which, of course, admit of considerable improvement, as they are still in the first stages of development; notwithstanding this, remarkable results have already been attained as given in the follow ing table :

Where working.	Capacity.	Steam pressure lbs. per square inch.	Condensed pressure lbs per square inch.	Number of revolutions.	Temperature Centigrade, degrees.	Steam consumption per kw. hour—lbs.
Berlin Electric Supply Works.	1,365 kw.	130	2.1	3,000	294	19.6
	1,920 hp.	170	1.2	3,800	300	17.4
At half load..	850 kw.	116	9.2 per cent (vacuum)	3,000	290	20.3

ELECTRICAL STATION PRACTICE.

ARTICLE XXIX.

BY W. H. RADCLIFFE.

The storage battery, secondary battery, or, as it is most generally termed, the accumulator, has been developed within a few years from the experimental stage to a recognized factor in the operation of most small electrical stations and in the operation of many of the large stations where direct current is generated. Installed therein it serves as a means of equalizing the current and reinforces the generators during periods of heavy load.

As is well known an accumulator itself provides a method of apparently storing or accumulating current electricity. It does this by undergoing a chemical change when a current is forced through it in the reverse direction to that of the current it afterward supplies when disconnected from the source and placed on closed circuit. The form of accumulator best adapted for electrical station work is that of the Plante type. This type as manufactured by the Electric Storage Battery Company, one of the largest and best known concerns engaged in this business, consists essentially of three parts—the containing vessel or tank, the electrodes or plates, and the electrolyte or acid solution contained in the vessel or tank for excitation.

The containing vessel or tank may be either a heavy glass jar, a rubber jar, an all metal tank, or a wooden tank treated with acid-proof paint and lined with lead. Of these, glass jars and lead-lined wooden tanks are best adapted for station practice. The size of the jar or tank is governed by the size and number of electrodes or plates employed.

The electrodes or plates in each accumulator are composed primarily of an alloy of lead and antimony, the antimony being added to harden the lead. There are a number of perforations in each plate, and in these are pressed buttons of the same shape as the perforations which in the positive plate are round but in the negative plate are square. The buttons in the positive plate constitute the active material of the accumulator and consist of peroxide of lead (PbO_2) when the battery is charged. The positive plate is the one from which the current developed in the battery passes to the outside connecting circuit, and it is also the one whereat the charging current enters the battery; it may be distinguished from the negative plate by its color, which is a dark brown. The buttons in the negative plate consist of pure lead (Pb) and when the battery is charged are reduced to a state of fine subdivision. The negative plate may be distinguished from the positive plate by its color, which is a dark gray, and also by the fact that the number of negative plates generally exceed the number of positive plates by one in order that the latter may be placed to the greatest advantage.

The electrodes or plates in each accumulator vary in size and number, according to the capacity in ampere-hours it is desired to obtain therefrom. The unit "ampere-hour" means one ampere delivered for one hour. Thus, an accumulator having a capacity of 300 ampere-hours and delivering 30 amperes will, if permitted, continue to discharge at this rate for $300 \div 30$ or 10 hours and still retain the necessary amount of residual charge for preserving the plates. If a current greater than 30 amperes be drawn from the accumulator the time required to exhaust the original charge will be proportionately shortened, and if less than 30 amperes be discharged the time will be proportionately lengthened. An approximate rule to follow in calculating the capacity of an accumulator is to allow 6 ampere-hours for each square foot of positive plate surface.

The positive plates of an accumulator are all electrically connected together forming the positive terminal, and the negative plates are likewise connected together forming the negative terminal. The terminals of two or more accumulators may be joined in series or in multiple as with primary cells for increasing the total respective voltage or current developed. The connections between the accumulators in an electrical station are generally made by burning or fusing the lugs of the respective positive and negative plates to lead connecting strips, which method insures efficient and durable electrical contacts between them.

The electrolyte or acid solution contained in the vessel or tank for excitation is a mixture of pure sulphuric acid or oil of vitrol (H_2SO_4) and pure water (H_2O) in such proportions that the solution will have a specific gravity or density of 1.30 as measured with the hydrometer when the battery is fully charged and the solution at a temperature of 80 degrees Fahrenheit.

The chemical reactions that occur when the battery is charged and when it is discharged are as follows: When the charging process is completed the positive plate is covered with peroxide of lead (PbO_2), as previously stated, and the negative plate is covered with spongy metallic lead. During the discharge the lead at the negative plate combines with the sulphuric acid (H_2SO_4) and forms lead sulphate ($PbSO_4$) and hydrogen (H_2), the latter of which unites with the peroxide of lead (PbO_2) on the positive plate and forms lead oxide (PbO) and water (H_2O). The lead oxide (PbO) then combines with the sulphuric acid (H_2SO_4) and forms lead sulphate ($PbSO_4$) and water (H_2O). It is thus seen that considerable water is formed during the discharge, and this of course lowers the specific gravity of the solution. However, when the battery is again charged, the order just given is reversed and the conditions are practically the same as before.

When a new storage battery is installed and the accumulators are shipped directly from the manufacturers, the jars or tanks should be unpacked first, they should be thoroughly washed, their edges paraffined, and then placed permanently in position. The plates, which are usually boxed separately, may then be taken out if the acid solution is ready; if, however, the solution is not ready it is advisable to keep them well wrapped, as they are shipped dry and are easily injured by exposure. The cleaning of the plates must consequently be done before they are placed in the jars or tanks, and for

the purpose a pair of air bellows will be found very convenient in blowing out from the crevices without damage to the plates, any particles of foreign matter such as the material used in packing that may be lodged therein. Every effort should be made to have the working parts of the battery as clean as possible before pressing them into service, else short-circuits between the plates will be of common occurrence, and much trouble may be expected in consequence. In assembling the plates in the jars they should be so placed that the positive terminals and negative terminals of the accumulators are in such positions relatively to each other that connections may readily be made between them.

To prevent the neighboring plates of an accumulator coming in contact with each other, and thus causing an internal short circuit, separators consisting of sheets of wood and rubber are placed in each accumulator between the plates. The wooden portion of each separator consists of a thin web of selected wood, one side of which is flat and the other side grooved. The flat side is placed against the surface of the negative plate, while against the ribs formed by the grooves rests the rubber portion of the separator. The rubber is in the form of a thin perforated plate, and when this is placed against the wooden ribs previously mentioned, it serves to keep the plates the proper distance apart and at the same time permits a free circulation of the electrolyte through the channels formed by the wooden grooves. Although the wooden portion of the separator is not perforated, it is thin and absorbs enough of the acid to afford sufficient conductivity for the current.

As previously stated, the connections between the accumulators are generally made by fusing the leaden lugs of the plates to leaden strips; the strips have each a length equal to the widths of the accumulators, and they are composed of lead so that there will not be two different kinds of metals connected together, for under such conditions there would be a tendency for galvanic action to take place and impair the connections. In order to prevent sulphuric acid fumes from attacking the exposed terminals, these and other bare conductors in the battery room should be painted with a sulphuric acid proof paint such as can be made by dissolving shellac in wood-naphtha. Part of this paint may be colored red by adding vermilion and this may be used on all the positive battery terminals, while the remaining portion of the paint may be colored black by adding lamp-black and used on all the negative battery terminals. It will be found that, if the terminals be thus painted, no confusion will ever arise as their method of connection and many mistakes will thereby be prevented.

Thus far, both plates and separators are dry, but now the electrolyte is to be added. It should be given a density of about 1.17 by adding a certain quantity of water to concentrate sulphuric acid, and the mixture should not be poured into the accumulators until it is perfectly cool; after it has been introduced, the charging process should not be commenced for at least 12 hours in order to allow the electrolyte to thoroughly soak into the wooden separators. In diluting the acid, it must be remembered that the acid should be poured into the water, not water into the acid, as in the latter case explosions of more or less violence are liable to occur. Sufficient of the solution should be placed in each accumulator to fill them about one-half inch above the tops of the plates, and this distance should afterward be maintained constant in service.

The working parts of the battery being now in readiness the accumulators should all be connected in series with the source of current, the positive terminal of the battery being joined to the positive terminal of the charging generator or supply circuit and the negative terminal of the battery to the negative terminal of the generator or supply circuit. The generator supplying the charging current must necessarily be of the direct current type, and it should preferably be shunt wound.

Its rated electromotive force should measure at least 50 per cent. above the normal voltage of the battery to be charged, allowing 2 volts per accumulator as the normal voltage. If there is any possibility of the normal voltage of the battery when fully charged rising above the rated voltage of the charging generator employed an automatic switch should be connected in circuit between them so that any reversed current will operate this switch and open the circuit. A rheostat connected in the shunt field winding of the charging generator will be found very convenient for regulating the strength of the charging current, but if the wires of a supply circuit are used a rheostat connected in series with the battery and said circuit will answer the purpose.

The pressure of the charging current at the beginning of the charge need ordinarily be only about 2 or 5 per cent. above the normal voltage of the battery, its exact value being such as to maintain the passage of a constant current through the battery at all times during the charging process. The value of this current depends somewhat upon the design of the plates, and should in every case be obtained accurately from the manufacturers, but in general it is about 8 amperes per square foot of total surface of the positive plates undergoing charge. If the value of this current be exceeded, injurious results will follow, as will be shown later, and the plates will also suffer if the charging current be allowed to fall below one-tenth of its maximum value. As the charging process continues the back electromotive force of the battery increases, and in order to keep the charging current constant the applied voltage must be raised from time to time until, just before the charge is completed, it will probably be necessary to raise it nearly 40 per cent. above the normal voltage of the battery.

In some cases no means are at hand for keeping the charging current constant, and when the conditions are thus, the time required for the charge will be very much longer than would otherwise be the case. The reason for this is, that whereas at the start the current will be normal owing to the application of the proper voltage, it will afterward become less and as the number of ampere hours required to charge the battery is the same whatever be the value of the current the time must necessarily be increased when the charging circuit is below its normal value.

It is necessary to be particularly watchful of the internal temperature of the battery during the initial charge, and if this temperature rises to 100 degrees Fahrenheit the charging current should be reduced or stopped entirely until a temperature of about 80 degrees is again attained; in consequence, the initial charging rate should be made much lower than normal. During the first part of this charge the specific gravity of the electrolyte will fall somewhat below 1.17 but it will afterward increase, and the charge should be continued until the density is about 1.27 for the first charge, at which time the voltage of each accumulator should be approximately 2.4 volts. In following charges the process should be continued until the normal value of 1.30 be registered on the hydrometer scale and the voltage per accumulator be about 2.55 volts. Still another means is available for judging when a charge is nearly completed, and that is the electrolyte which at this stage assumes a milky appearance caused by the rising of gas bubbles through the solution. When this occurs the electrolyte is said to be boiling, although the boiling is not that due to a high temperature but to the peculiar appearance of the liquid. It may happen

that the accumulators do not all boil equally; this, however, need not cause apprehension unless in one or more of them there is no boiling whatsoever. An accumulator behaving in this manner should be disconnected from circuit for a time, during the discharge of the battery, so that it will average up well during the next charging process. Ideal conditions, it must be remembered, are attained only when all of the coils have the same amount of charge.

THE STORAGE BATTERY IN SMALL CENTRAL STATIONS.*

BY J. M. S. WARING.

Owing to the impossibility of drawing any distinct line separating storage battery practice in small central stations from that in the larger stations, and to the fact that many or most of the economies and advantages effected are common to all direct current stations, irrespective of their output, I have decided to deal with this subject in the following way:

First, to cite a battery application peculiar to small stations, and then to dwell briefly on the features common to all central stations.

In the first case the consideration will be that of a lighting station in a small village. In such cases it usually proves unprofitable to furnish continuous service throughout a 24-hour day, as the demand for current during the early morning hours and throughout the greater portion of the day would be so small that the additional shift of men required and the increased fuel consumption on the plant would prohibit the commercial success of the venture.

It is, however, true that the manager of a central station operating only a night schedule is greatly handicapped. In order to secure any great amount of residential lighting business continuous current must be supplied, as the owner of a residence would naturally demand light during all hours of the night, and would further probably demand fan service throughout the day during the summer months. If these facilities cannot be offered to the public the amount of business of the small central station is necessarily limited.

As an illustration of what has been accomplished along this line I might cite a case in actual practice where the conditions were as follows:

The plant I have in mind consisted of one 60 and one 120 hp. non-condensing engine, which in addition to driving certain machiney operated two 125 volt generators, one having a capacity of 20 and the other of 25 kilowatts, the two being operated in combination on a three-wire Edison system, with 220 volts across the outside mains. This plant had been operating and supplying a load concentrated within a very small radius. The maximum peak load of 150 amperes was on the station for about an hour and a half in the evening—that is from 6:30 until 8; it then gradually decreased to about 10 amperes at 11 o'clock at night, and at 12 the plant was shut down.

An opportunity arose for this plant to obtain the contract for city lighting, but the cost of the necessary transmission line, including poles, copper, etc., amounted to so much that the returns from the city lighting alone would not warrant the investment; however, it was obvious upon investigation that if a sufficient amount of residential lighting could be assured the investment would become a decidedly paying one, and with this in view a storage battery was installed. This installation made, the station continued to operate for the same number of hours daily. On account of the new business the load was materially increased. From 12 o'clock (midnight) until dusk in the afternoon the entire load was taken care of by the battery.

While this was a three-wire system with 220 volts across the outside mains, only a 110-volt battery was installed, for, during the hours that the battery was operating, the load was so light that by connecting the two outside mains together at the station the system could be operated by a two-wire 110-volt system, and even under these conditions, owing to the light load, the drop was considerably less than when operated as a three-wire system with the maximum load. In this case, there was an increase in load after the installation of the battery of about $66\frac{2}{3}$ per cent., and an increase in fuel consumption of only about 25 per cent., showing that the cost of fuel per kilowatt hour was decreased about $37\frac{1}{2}$ per cent., this decreased fuel consumption being due to the fact that the generator set, while operating with the battery, was run at a considerably higher percentage of full load than was the case before, the efficiency being correspondingly increased.

Another instance which occurs to me is similar to the above, with the exception that the plant supplied the adjacent district from a three-wire direct current system while in the outlying districts the load was on an alternating system. While this alternating load was extremely heavy during the peak it was very light during the day, consisting only of a small amount of fan service in the summer months. A battery was installed in this plant which furnished current directly to the direct current mains and at the same time operated a direct current motor running a small alternator so that the fans on the alternating current system could be operated.

These, and cases of a similar nature, are, of course, confined to very small plants.

Another application of the storage battery, which is irrespective of the size of the plant, is that of a battery operating in conjunction with a water power plant. A number of cases have come before the attention of the writer where there was sufficient water power to supply considerably more than the load existing during the greater portion of the 24-hour day, the peak load during the evening hours, however, being in excess of the capacity of the turbines. In this case the value of the battery is apparent, as the generators while carrying the day load are charging the battery at the same time, the battery assisting to the extent of its capacity during the peak, thus giving an increased station capacity which would otherwise be only obtainable by the addition of an auxiliary steam plant, with a correspondingly increased cost of operation, which would probably make the investment prohibitive.

There are a number of features which may now be briefly mentioned as being of interest to the central station manager, regardless of the size of the plant he is operating.

To the central station manager a minimum cost of production and transmission, allied with reliability of service, are essential. The consumer, however, demands that the latter item be not sacrificed in the pursuit of economy. Intermittent service results in a loss of business to the central station, and, while it may be difficult to compute the expense to which a lighting station is subjected by a 10 or 15 minute interruption, the official who receives the complaints of his customers fully realizes that a loss of revenue does result from frequent recurrences of this complaint. The storage battery insures increased economies of production and transmission, at the same time almost entirely preventing interruptions to service. A battery at the source of the direct current transmission—that is to say, in either a direct current power house or a rotary sub-station—will offset, in the first place, the installation of a corresponding capacity of boilers, engines and

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

generators. In the second case that of a rotary sub-station—in addition to this apparatus it will also offset a certain proportion of the static transformers and rotary equipment, with the cost of which apparatus that of the battery will compare favorably. It is of the greatest value as a reserve in either case, tiding over shut-downs occasioned by trouble on any of the apparatus just mentioned, or in the high tension line in the latter case. The battery, being ever present on the system, is readily available as a reserve.

It further obviates the necessity of carrying boilers under steam in anticipation of a peak load, thus insuring a decreased fuel consumption.

Another familiar application of the storage battery is that of placing it at the center of load on a direct current system of distribution. When the volume of business in a congested locality covered by a low tension system of transmission reaches a certain volume (and the more remote this locality from the central station the sooner this point is reached), the amount of copper required to care for the power from the central station necessitates an outlay tending to render this system of transmission prohibitive. By the installation of a battery of a capacity sufficient to care for a certain portion of the peak, the amount of copper between the central station and the center of load is decreased to such an extent that the battery investment is decidedly the preferable one from a commercial standpoint.

One of the more recent adaptations of the storage battery, and one whose importance will readily be recognized by central station managers, is its use in connection with the direct current exciters in alternating current power and lighting plants. With an installation of storage batteries floating at all times on the exciter bus, interruptions of current in the exciter circuit are practically obviated. Reduced fluctuations of the exciter voltage are assured, together with corresponding reductions in the alternating current voltage fluctuations. Where alternating current motors are used to drive the exciters, the battery also serves to supply field current when starting up the plant after a shut-down. An attractive feature in any battery installation is its adaptability to changes of conditions over a very wide range. Its capacity or voltage may be increased or decreased by varying the number of plates per cell or the number of cells in series without affecting in any way the original installation, thus obviating the necessity of anticipating any future increase in business.

It may be said in general that there are few direct current systems on which the service may not be improved, the liabilities of interruption decreased and the operating expenses minimized, by the use of a storage battery auxiliary.

MERSEY RAILWAY ELECTRIFICATION WORKING RESULTS.

(From our London Correspondent.)

A description of the electrical equipment of the Mersey Tunnel Railway appeared in ELECTRICITY for May 27, 1903. It will be remembered that after many years of hopeless struggling with the smoke problem in these tunnels, and the difficulty of obtaining satisfactory results with a system of steam locomotion whose operating costs amounted to 90 per cent. of the gross receipts, electric traction was hailed as the only possible chance of salvation and by making certain financial arrangements with the Westinghouse Company the conversion was carried out, and the line opened for public service on May 3, 1903.

Electrical engineers have naturally been following the working of the system with considerable interest as it is the first English system to complete the change over from steam to electricity, and the results which have followed upon the first ten months' running are now being studied closely. Such data as is interesting from an engineering point of view was disclosed to a meeting of the Manchester Institution of Electrical Engineers on March 1 by Mr. H. L. Kirker in a paper on "The Mersey Railway—Multiple Control." Before passing to a review of these results we should like to incidentally mention one point in connection with the conversion which may serve to illustrate something of the sort of work that the contractors had to do. The work on the permanent way in the tunnel was of such a disagreeable nature that difficulty was experienced in retaining the men. The actual working hours were from 12:30 till 4:30 A.M., except on Sundays, when they were extended to noon, but the air was never free from smoke. The greater part of the cable work was in the ventilation headings, and here there was, in addition to the smoke, a 17 years' accumulation of soot to contend with.

The steam plants which formerly did service for ventilating the tunnels were suppressed, and two 12 ft. and one 5 ft. motor-driven fans installed at stations, and generally speaking the two former are quite sufficient to ventilate the tunnel quite satisfactorily. Each 12 ft. fan, in normal operation, moves 65,000 cubic feet of air per minute with a consumption of 24 hp.

At the power station the mechanical coal handling arrangements, the feed water system, and the storage battery, have proved important elements in the production of cheap power; further, an efficient application of this power has been secured by the location of the power house at a point where the losses in conductors and the investment in cables are at a minimum, and by the use of multiple unit train control.

A comparison of the working results for the period mentioned, with the original engineering estimates, was made by Mr. Kirker. Taking first the cost of ventilation. This under steam conditions cost on the average more than £2,400 per half year; but with electric traction it is now less than £200 for a half year, and this is well within the engineers' estimate. As to schedule speed, with steam the rate was 15 miles per hour, but electric traction was laid out on a basis of 20 miles per hour, and this has been attained. With the steam locomotives the train mileage was less than 6,000 per week, but during the last quarter of 1903 the electric trains lacked but 40 miles on an average of 15,000 miles per week. At this rate the total mileage for the year will considerably exceed the original estimate. It was estimated that the coal consumption would not exceed 4 lbs. per kw. hour (average) at the switchboard. The average for the last quarter of 1903 and the first six weeks of 1904 is said to be under the 4 lbs. The consumption of energy for a loaded three-car train was estimated not to exceed 9.25 kw. hours per train mile; for the last quarter of 1903 the actual figure was less than 9. As regards the cost of operation per train miles, it was estimated that the power house expenses, the cost of power for operating and lighting trains, the maintenance of electrical equipments, cars and collector rails, would not exceed 6.75d. per train mile for an average train 230 ft. long, and weighing 105 tons, including motors. The actual figure for the last quarter of 1903 falls below this estimate.

The corresponding cost per steam train 200 ft. long and weighing 77 tons, exclusive of locomotive, but working at a schedule speed of 15 miles per hour instead of 20, exceeded 11d. per train mile. It required an 80 ton locomotive to haul the 77 ton steam train.

The total power station cost made up of

maintenance and operation (coal, water, oil, waste, sundries, and labor) did not exceed .35d. per kw. hour during the last quarter of 1903.

These results are considered to show that the original engineering estimates have been practically fulfilled.

What effect the electrification has had in bringing back traffic which had been lost through the former unsatisfactory system is not yet known. This will be announced shortly. In the early months of electrification the increased traffic was not so great as had been expected but things are thought to have improved considerably as the improvements in the system have become properly known and appreciated.

National Electric Light Association Notes.

Mr. Charles L. Edgar, president of the National Electric Light Association, was in New York several days last week looking after association affairs. President Edgar was accompanied by past president James I. Ayer, whom he has been fortunate enough to induce to act as chairman of the entertainment committee of the 27th Convention, to be held in Boston, May 24–27.

The entertainment committee, among its other duties, will have charge of assigning rooms at the Vendome, which is to be the headquarters of the association, and particulars regarding rates, etc., will be issued very soon. As many delegates prefer to stop at a smaller or quieter hotel than that selected for convention headquarters, arrangements will be made by which they also can secure through the committee such accommodations as they prefer. In fact, hotel arrangements promise to be more systematic and satisfactory than they have ever been before.

The preliminary questions for the question box of this convention have just been sent to members. This list is nearly twice as large as the completed list for last year's convention, and there is every indication that the question box for the coming convention will be not only the largest but the most systematic and comprehensive ever presented by the association.

Mr. C. O. Baker, Jr., for so many years the popular and efficient master of transportation for the National Electric Light Association, has resigned from that position. Mr. Baker expects to be in Europe at the time of the Boston meeting, and feels that he should not continue in the office unless he can personally attend to the duties connected with it. President Edgar has appointed Mr. George F. Porter to succeed Mr. Baker. Mr. Porter had charge of transportation matters before he became secretary of the association, and organized special trains for the Detroit convention, February, 1887; the Chicago convention, February, 1889, and the Kansas City meeting, February, 1890. During the ten years that he was secretary he of course had more or less to do with transportation arrangements, and being very popular with the railroad people as well as with the delegates to conventions, his appointment is another instance of President Edgar's good judgment in selecting men to work for the welfare of the association.

New York Electrical Society.

In response to an invitation addressed to him by a number of his friends, members of the Society and of the American Institute of Electrical Engineers, Mr. Oscar T. Crosby, E.E., the distinguished engineer and explorer, has consented to deliver a lecture entitled "Things Seen in Turkestan and Thibet," at the lecture room of the American Institute, 19 West 44th street, this (Wednesday) evening, March 23, at 8 o'clock.

American Electrochemical Society.

The following papers will be read at the Washington, D. C., meeting to be held April 7, 8, and 9:

"The Composition and Resolution of Voltages," by Dr. J. W. Richards; "Notes on the Industrial Electrolysis of Water," by W. S. Landis; "Standard Cells," by Dr. F. A. Wolff; "Electric Smelting Experiments for the Manufacture of Ferro-nickel from Pyrrhotite," by Ernst A. Sjostedt; "A Contribution to the Study of the Electric Arc," by Dr. William S. Weedon; "The Energy of Ions," by Dr. L. A. Parsons; "Some Experiences in Copper Precipitation," by Hermann Poole; "The Preparation of Materials for Clark and Weston Standard Cell," by Dr. H. S. Carhart and Dr. G. A. Hulett.

A large number of papers besides the above will be read.

Society of Chemical Industry.

The next meeting of the New York Section will be held at the Chemists' Club, 108 West 55th street, on Friday evening, March 25. The following papers will be read: "Analysis of Jalap," by Russell W. Moore; "Acetic Acid in Acetate of Lime," by Albert G. Stillwell; "The Preparation of Cotton Fiber for Surgical Uses" (illustrated by lantern slides), by F. B. Kilmer, and "Cupellation of Platinum," by W. J. Sharwood.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 15, 1904.

Electric Railways and Appliances.

754,406. Electrically-Operated Stopping Means at Railway Danger Signals. William L. Adamson, Philadelphia, Pa. Filed June 12, 1903.

754,565. Electric Railway. Rudolf A. E. Huber and Hans H. C. Behn-Eschenburg, Zurich, Switzerland, assignors to the Maschinenfabrik, Oerlikon, Switzerland. Filed Dec. 23, 1901.

754,652. Trolley-Hook for Manipulating Self-Loading Grabs. Frank K. Hoover and Arthur J. Mason, Chicago, Ill. Filed May 21, 1903.

754,778. Trolley-Wheel Retainer. James A. Kilpatrick, Niles, O. Filed Dec. 19, 1903.

754,832. Electric-Railway Plow. John H. Akers, Washington, D. C. Filed Aug. 8, 1903.

Electric Lights and Appliances.

754,694. Electric Pocket-Lamp. Angelica E. Post, Boston, Mass. Filed Dec. 30, 1903.

754,762. Electric-Socket Support. Edwin R. Gill, New York City. Filed March 14, 1902. Renewed Dec. 23, 1903.

Electrical Machinery and Apparatus.

754,496. Limiting Device for Electric Circuits. Charles W. Potter, Denver, Col. Filed Feb. 10, 1902.

754,505. Automatic Circuit-Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company. Filed June 18, 1903.

754,638. Transmission-Gear. Patrick H. Brennan, Syracuse, N. Y. Filed Dec. 21, 1903.

754,666. Induction-Coil. Reuben Miller, Jr., Pittsburg, Pa. Filed Jan. 7, 1904.

754,689. Electrical Selective Apparatus. Frank D. Pearne and Charles L. Krum, Chicago, Ill., assignors to the Pearne Electric & Manufacturing Company, same place. Filed Feb. 3, 1902.

754,748. Electric Stop-Motion for Warping-Machines. John Cocker and Charles Denn, Philadelphia, Pa. Filed Jan. 30, 1902.

754,804. Speed-Regulating Magnetic Clutch. Charles A. Pratt, Oakpark, Ill. Filed Dec. 7, 1903.

754,863. Electrical Plug and Receptacle. Gilbert W. Goodrich, Bridgeport, Conn., assignor to the Bryant Electric Company, same place. Filed Oct. 9, 1903.

Telephones and Telephone Apparatus.

754,457. Telephonic Relay or Repeater. Isidor Kitsee, Philadelphia, Pa. Filed July 7, 1899. Renewed April 25, 1902.

754,556. Telephone Receiver Support. Harry L. Goodwin, Kansas City, Mo., assignor of one-half to Charles N. Lavery, same place. Filed May 25, 1903.

754,646. Antiseptic Telephone Mouthpiece. William M. English and Arthur H. Ten Broeck, San Francisco, Cal. Filed April 27, 1903.

Miscellaneous.

754,410. Electric Time Alarm. Emil M. Benesch, Denver, Col. Filed March 7, 1903.

754,429. Means for Electrical Distribution. John L. Creveling, New York City. Filed May 10, 1901.

754,451. Electrical Water Heater. Harry M. Hill, St Louis, Mo., assignor to the Hill Electric Manufacturing Company, same place. Filed June 1, 1903.

754,465. Automatic Electric Heat Regulator. Daniel N. Leib, Elkhart, Ind., assignor to the Automatic Heat Regulator Company, same place. Filed April 10, 1902.

754,534. Thermostatic Gas Detecting Means. James E. Baldwin, East Williston, N. Y. Filed Sept. 10, 1902.

754,622. Electric Clock. David W. Thompson, Chicago, Ill. Filed Dec. 5, 1895.

754,637. Electromagnetic Gun. Kristian Birkeland, Christiania, Norway. Filed Jan. 2, 1902.

754,656. Electric Furnace. Charles A. Keller, Paris, France. Filed Jan. 17, 1902.

754,660. Rheostat. Lamar Lydon, New York City, assignor to the National Battery Company, Buffalo, N. Y. Filed Aug. 8, 1902.

754,681. Electromagnetic Device. Eugen K. Muller, Zurich, Switzerland. Filed Sept. 20, 1902.

754,692. Rheostat. Claude R. Pitrat, Amsterdam, N. Y., assignor to the Magneto Electric Company, Incorporated, same place. Filed Aug. 8, 1903.

754,756. Process of Separating Ores from Magnetic Gangue. Thomas A. Edison, Llewellyn Park, N. J. Filed May 29, 1903.

754,858. Storage Battery Tray. Thomas A. Edison, Llewellyn Park, assignor to the Edison Storage Battery Company, Orange, N. J. Filed Nov. 28, 1902.

754,859. Reversible Galvanic Battery. Thomas A Edison, Llewellyn Park, N. J., assignor to the Edison Storage Bttery Company, Orange, N. J. Filed Nov. 28, 1902.

THE TELEPHONE WORLD.

Higher Telephone Rates in Kentucky.

Beginning with the 1st of April the Fayette Home Telephone Company of Lexington will increase its rates from $2.50 per month for business houses to $3.50, and from $1.50 for residences to $2.50 per month. The Fayette Fiscal Court lately canceled the restriction in the franchise which bound the company to give a service of $1.50 for private residences and $2.50 per month for offices. Some weeks ago the attorneys of the company secured the passage of an ordinance in the city council securing the same privilege from the city. It is predicted that this will put an end to the liberal rates for telephone service in Fayette County, if not in Central Kentucky.

The Home Telephone Company, recently organized by the farmers and business men of Oldham County, Ky., has a large force of men at work hauling poles from Beard to be used in the construction of its main line, which is to run via here to Middletown, where it will connect with the Home Telephone Company's line.

A quarterly dividend of 1¼ per cent. on preferred stock was lately announced at the annual meeting of the stockholders of the Iowa Telephone Company held in Davenport before moving to Des Moines, where in the future the headquarters of the company will be located.

The Kuntz International Telephone Company of Washington, D. C., capitalized at $10,000,000, has the following incorporators: J. W. Kuntz, J. A. Thompson, Harvey T. Winfield, Joseph A. Roth and Charles W. Fitts.

The Hermon & St. Augustine Telephone Company of Hermon, Ill., capitalized at $10,000, will build and operate a telephone system. W. A. Bogan, George M. Brown and George Castle are the incorporators.

The articles of incorporation of the Iowa Telephone Company of Tama were lately filed with the Secretary of State. The capital is $15,000 and incorporated by C. W. Smith and L. P. Crittenden.

The Farmers Co-operative Telephone Company of Hendricks County, Ind., capitalized at $10,000, has as directors Samuel Jordan, Abraham Hoadley, Alva Ross, G. L. Christie, William Moon, John Ules and J. T. Jones.

The Chicago Telephone Company is to erect an exchange and office building on Washington street. The company has a 99-year lease at an annual rental of $8,000. The building will be 16 stories, and will cost about $600,000.

The Riverton Telephone Company has been organized at Sharptown, Neb., and will erect a telephone line from Mardela Springs via Riverton to Sharptown.

The farmers in the southwestern portion of Fillmore County, Neb., are constructing an Independent telephone line.

New Rochelle, N. Y., is to have a new telephone system installed about May 15

Five-Cent Telephones to go Out of Service.

Representatives of the Bell Telephone Company, says a New Jersey paper, are informing persons who have what are known as "five-cent-a-call 'phones" that the present system of payment for such services is to be discontinued and that after April 1 such telephones will cost the subscriber $1 a month.

It has been the plan in the past that such telephones were paid for by the call and at the rate of five cents for each use. By the new plan the service will cost $12 a year. This condition will be applicable to those patrons who have these 'phones in their homes at present.

It is the purpose of the company in making this change to decrease a great amount of detail work at the central office. Under present conditions each call has to be recorded and at the end of the month slips made out showing to the subscribers the number of calls during the month. This method is a long drawn out one and is not considered practical.

The Western Dixie Telephone Company has been organized at Vale, Tenn., with E. B. Simmons, president; Dr. Florence, vice-president and A. N. Presson, secretary and treasurer. This company has lines running from Camden to Huntington, with a number of subscribers at both places, and several branch lines, giving connection with all places along and near the main line. It is the intention of the promoters of the company to obtain a charter at an early date and do a general telephone business.

News from Knoxville, Tenn., states that the fight brought on by the merchants some months ago against the East Tennessee Telephone Company has now practically been abandoned, and the company is restoring its service in a large number of business houses. Manager Williams says that the only difficulty experienced at present is that of installing the instruments as rapidly as the subscribers desire. It was only on the question of an advance in the price of 'phones that the fight on the company was made.

A charter was recently issued in Charleston, W. Va., to the Wheeling & Pittsburg Telephone Company of Wheeling, to construct and operate a telephone line. Its capital stock is $100,000. Incorporators: J. A. Howard, J. P. Young and F. C. Handlan, of Wheeling; R. C. Hall and J. G. Plant, of Pittsburg.

A telephone company has been organized at Mexico, Ind., with a capital stock of $2,000. The town will be supplied with 'phones, and communication established with neighboring towns. The officers are: Lewis Bond, president; W. E. Fisher, vice-president; Leroy Graft, secretary, and J. T. Hood, treasurer.

The net output of the American Telephone & Telegraph Company decreased 9,347 instruments for the month of February, making a decrease of 42,108 instruments since December 20 last.

Messrs. Denton and Newbern are putting in a telephone exchange in Broxton, Ga., and will have it in operation by April 1.

Missouri Has New Telephone Company.

The Missouri River Telephone Company, capital stock $150,000, half paid in, lately filed articles of incorporation with the county recorder. The company is composed of J. E. Zeluff, of Kansas City, who owns 1,000 shares; Walter S. Dickey, of Kansas City, 50 shares; W. T. Rankin, Tarkio, 200 shares; Frank S. Travis, and John R. Stafford, both of Tarkio, each 100 shares, and Ralph O. Stauber, St. Joseph, 50 shares.

The board of directors is composed of Walter S. Dickey, W. T. Rankin, Frank S. Travis, John R. Stafford and Ralph O. Stauber. Mr. Stauber is the agent of the company, the headquarters of which are to be maintained in St. Joseph.

A new protective device known as the phonalarm is so arranged in conjunction with the telephone circuits that when a door or window which is provided with the alarm is opened a signal is transmitted to the telephone exchange and the police headquarters are therefrom communicated with. The company's arrangement is so delicate that when a pane of glass in a window is broken the alarm is transmitted

The Independent companies of Vermont recently held a meeting at Hardwick. Twenty officers were present, representing six companies. Arrangements were made for the construction of a first-class trunk line from St. Johnsbury by Danville and Hardwick to Montpelier and so arranged that Montpelier can be called from St. Johnsbury direct.

At a recent meeting of the Lake City, Minn., council a resolution was passed to place before the voters the proposition of the municipal ownership and operation of a telephone system within the corporate limits of that city. It will be voted on at the election to be held on April 5. The city owns its waterworks and electric lighting plant. The telephone system now in operation is owned by private parties, but is being operated without a franchise from the city council.

A recent announcement from Cincinnati, O., says that the Norwood Citizens' Telephone Company has been granted a 25-year franchise by the Norwood council. This action was not taken without considerable opposition, and it was adopted by a very narrow margin. One of the immediate effects of the granting of this franchise will be to bring the Independent telephone companies a step nearer to Cincinnati.

The Farmers' Telephone Exchange Company of Caldwell, O., was lately incorporated at Columbus, O., with a capital stock of $10,000. The line will run from Caldwell to Cambridge, Zanesville, McConnelsville, Marietta and Woodsfield.

Telephone Incorporations.

The Sherburne Telephone Company, Sherburne, N. Y. Capital stock, $10,000. Incorporators: Jesse H. Shepard, Frederick I. Shepard and George L. Shepard.

The Troy Telephone Company, Troy, Ill. Capital stock, $10,000. Incorporators: J. H. Steinhaus, J. W. Gornet and Chris Busse, Jr.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Addison, O.—This town may be lighted with electricity, the current being secured from Springfield.

Albany, N. Y.—Members of what is known as the Bolton Road Colony, who own summer homes along the west shore of Lake George, have petitioned the Hudson River Water Power Company to string its wires along the shores of the lake to furnish light and power to run electric launches and for other purposes.

Anderson, Ind.—Commissioners of the municipal electric light plant announce that on April 1 a 30 per cent. reduction will be made in rates for electric light service here.

Baltimore, Md.—The Maryland Telephone & Telegraph Company proposes to enter the field as a competitor to the United Electric Light & Power Company for the electric lighting business of this city.

Bartlett, Tex.—It is reported on good authority that capitalists will submit a proposition to establish an electric light plant to supply this place, Granger and Holland with light. The people here favor the scheme.

Carmi, Ill.—The matter of purchasing an additional engine and dynamo for the electric light plant has been referred to the committee on electric lights.

Chesterfield, Ind.—A system of waterworks and an electric light plant will be added to the camp grounds this season.

Colima, Mex.—The city council has approved the project submitted by Messrs. Ugary and Garcia for the installation of an electric light plant here.

Duquoin, Ill.—The city council is contemplating the erection of an electric light plant.

Georgetown, Ill.—W. C. Dukes and Edward Cooley have been given a 20-year franchise for an electric light plant for this city. The plant is to cost $10,000, and have 1,200 lights at the start.

Hancock, Mich.—The citizens voted favorably on the proposition to build a municipal electric light plant next month.

Harmon, Ill.—The people here are considering the advisability of installing a public electric lighting plant.

Havana, Ill.—A special election will be held here in April to vote whether or not the city shall own and maintain an electric lighting plant.

High Springs, Fla.—The citizens may soon vote on a bond issue for an electric light plant and waterworks.

Kissimmee, Fla.—It has been recommended that this city install a new 90 kw. alternator and 150 hp. engine in its electric light plant; also a new wire system and series arc system is recommended.

Lakeview, O.—Pearl Kearns has secured the contract for putting in an electric light system here.

Linton, N. D.—This town may get an electric lighting plant.

Monclova, Mex.—A company has been organized here in the State of Coahuila, with Jose M. Tejada as president, to put in an electric light plant, the subscribed capital being $40,000.

New Castle, Wyo.—The Cambria Fuel Company will construct a line between Cambria and this place, and supply this town with electric light and power from the plant at the Cambria mines.

New London, Wis.—This city has purchased from local capitalists the municipal electric lighting plant. Extensive improvements will be made. The city has borrowed $10,000 from the State.

Newtown, Pa.—After four months' consideration the borough council has decided in favor of lighting the town by electricity and has granted a three-years' contract to the Newtown Electric Railway Company.

Ocilla, Ga.—Bids are being asked for installing an electric light system. J. G. Walker is mayor. The amount of $5,000 is reported available.

Papillion, Neb.—The installation of an electric plant is being discussed here.

Pinckneyville, Ill.—The electric light plant here was lately destroyed by fire, causing a loss of $10,000.

Princeton, Ind.—The electric light plant here is to be remodeled and enlarged.

Rathdrum, Ida.—M. D. Wright and Mr. Richards, of the Washington Power Company, are looking over the town and trying to make arrangements for the installing of an electric light plant.

Sayre, Okla.—This city is to have an electric light system soon.

Sheboygan, Wis.—This city recently purchased the electric light and power plant.

Tepic, Mex.—The city council is seriously considering the project to establish an electric light plant.

Vernon, Tex.—The electric light plant was destroyed by fire a short time ago. The property was owned by H. D. Rockersmuth and was insured for about half its value. The estimated loss is about $3,500.

Wayland, Mich.—This city is to have an electric lighting plant. The council lately granted a franchise to Walbrecht & Duel, who will soon commence work.

West Bay City, Mich.—The council has decided to submit at the next election a proposition to bond the city for $60,000 for electric light improvements.

STREET RAILWAYS.

Alamo, Tenn.—Rush A. Persons and Sam Wallace have just returned from their trip through the country along the line of the proposed electric line to the Mississippi River and state that it will certainly go through. A meeting of the citizens of this place was held on their arrival and $50,000 was subscribed for the line.

Cairo, Ill.—The Cairo Electric & Traction Gompany has petitioned for the right of way along the county road.

Chicago, Ill.—The car barn of the Chicago Union Traction Company was destroyed by fire last week. About 600 summer cars stored in the building were burned. The loss is estimated at $150,000.

Cumberland, Md.—Work has been begun on the new electric car line to connect Westernport with Keyser, W. Va., and the road will be pushed rapidly to completion. The line will connect with the Cumberland & Westernport Electric Railway.

Evansville, Ind.—Judge W. N. Harding, of Indianapolis, representing capitalists of that city, has been here with F. J. Sholtz to inspect several routes for the proposed electric interurbans from this city to the surrounding towns.

Far Rockaway, N. Y.—A new trolley line is to be constructed by the Long Island Railroad Company along the Boulevard, from here west to the newly developed section known as Bell Harbor. The object of this is to divert traffic from the steam tracks, over which the Rockaway trolley line now runs.

Liberty, Ind.—A 50-year franchise has been granted to the Interstate Traction Company to extend the line from Dayton and Camden O., through this town, to Connersville. The company also contemplates the extension to Chicago through a portion of the State now traversed by electric traction roads. It is promised that this division of the road will be completed for operation by December of 1905.

Meriden, Conn.—The Wallingford Tramway Company holds a franchise to build a trolley line from here to Montowese.

Mineola, N. Y.—The Mineola, Roslyn & Port Washington Traction Company will soon begin work on the construction of its lines.

New York City.—The New York City Street Railway Company and the Brooklyn Rapid Transit Company have agreed to co-operate in operating cars over the Williamsburg Bridge.

Peoria, Ill.—The Illinois Valley Traction Company has decided to build its interurban road from Utica west.

Penn Yan, N. Y.—The Lake Keuka & East Side Electric Railway Company will apply for a franchise to construct a road from this city to Keuka.

Richmond, Va.—The Seaboard Traction Company has been incorporated with a capital of $250,000. L. R. Britt, president.

Spokane, Wash.—The Washington Water Power Company is said to have secured the old Seattle, Lake Shore & Eastern right of way from here to Medical Lake and will build an electric line connecting the two places.

POWER PLANTS.

Blue Ridge, Ga.—The Blue Ridge Electric Light & Power Company is stated to be preparing to erect a power plant.

Helena, Mont.—The Ox Bow Power Company, recently incorporated in South Dakota, has under contemplation the construction of a dam across the Missouri River below this city, and the generation of electric power to be conveyed to Helena, Butte, Anaconda and other points. About $750,000 will be expended.

Vineland, N. J.—Local parties are discussing a project to utilize the Maurice River water power for generating electricity.

BIDS WANTED.

Hamilton, Ont.—Sealed bids in accordance with plans and specifications to be seen at the office of the Hamilton Cataract Power, Light & Traction Company, located at 128 King street, East, of which William C. Hawkins is general manager, will be received until March 31, for the construction of an enlargement of the hydraulic system.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12½@12¾c.; Lake 12⅝@12⅞c.; casting, 12½@12¾c.

The Chicago City Council has granted a franchise extension to the City Railway Company until January 1, 1905.

The stockholders of the Philadelphia Electric Company will hold its annual meeting in Camden, N. J., on April 13.

The General Electric Company has declared the regular quarterly dividend of 2 per cent., payable April 1 to stock of record March 24.

The Keystone Telephone Company of Philadelphia (independent) states that it has installed over 1,200 new telephones since January 1.

The Savannah (Ga.) Electric Company has declared a regular semi-annual dividend of $3 per share on the preferred stock, payable April 1.

The annual meeting of the stockholders of the American Telephone & Telegraph Company will be held at 15 Dey street, New York, on March 29, at noon.

The Rochester (N. Y.) Railway Company has declared the regular quarterly dividend of 1¼ per cent. on its preferred stock, payable April 1.

The Middlesex & Somerset Traction Company, which has 50 miles of track, has been sold to the Public Service Corporation of New Jersey for $1,250,000.

Directors of the Bell Telephone Company of Philadelphia have declared the regular quarterly dividend of 1½ per cent., payable April 15 to stock of record April 5.

At the annual meeting of the stockholders of the American Light & Traction Company, held in Jersey City on Monday, the retiring board or directors was re-elected.

It is understood that the directors of the Welsbach Company are seriously considering the question of removing its plant from Gloucester, N. J., to Buffalo, N. Y.

A postponed meeting of the United Traction Company of Albany, N. Y., will be held April 2, to consider the question of making a new mortgage and issuing bonds for $6,500,000.

The Connecticut Railway & Lighting Company has filed a mortgage for $1,000,000 in favor of the Central Trust Company of New York to secure an equal amount of bonds.

The Mexican Light & Power Company, which is controlled by Canadian capitalists, is said to be about to acquire the Federal Street Railway in Mexico City for $18,000,000.

The Heat, Light & Power Improvement Company of America was incorporated at Albany on Monday with a capital of $600,000. The office of the company will be in New York city.

The directors of the Metropolitan Street Railway Company of New York have declared a regular quarterly dividend of 1¾ per cent., payable April 15. Books close March 24 and reopen April 16.

Of the nine street railways in New York State which declared dividends during the last year the Schenectady Company shows the largest gross earnings per car mile, but the expenses were comparatively large.

The New York Railroad Commission has authorized the Albany & Hudson Railroad Company to issue an additional $100,000 under the mortgage heretofore consented to by the board. For new buildings and for improvements in construction and extension a large sum has been set aside.

EDITORIAL NOTES.

A Bill to Regulate Electric Wiring.

A bill introduced into Congress some time ago for the regulation of electric wiring in the District of Columbia has passed the Senate and is now in the hands of the Committee of the District of Columbia on the House side. This bill makes it unlawful for any person to act as an electrical wiring contractor or to engage in electrical construction or installation, who has not been licensed or is not working under the supervision of some person so licensed. This, however, shall not be construed as applying to the public buildings and grounds, or to the generation of power by incorporated companies engaged in the production of electrical current for public service or use.

The bill makes it unlawful for any person, firm, or corporation to operate, as owners or lessees, any electrical generating plant in the District without first securing a permit to operate same, and it shall also be unlawful for any person as an employe of any person, firm or corporation to operate any electrical plant or machinery for the generation or utilization of electricity for light, heat or power without first having obtained a license.

The commissioners would be authorized, in the event that the bill is enacted, to appoint an electrical board of three members, at least two of whom shall have knowledge of electrical lighting and power, one of the three to act as secretary and chief inspector of electrical work, the compensation to be two hundred dollars per annum, the men composing the board to be already in the employ of the District. The commissioners would be expected to prescribe the necessary rules and regulations, and all wiring and apparatus for the utilization and production of electric current for lighting, heating and power, and the installation thereof to be subjected to such tests as the commissioners may prescribe.

The commissioners, upon the recommendation of the board, would have the right to make such rules and regulations respecting the production, use, and control of electricity in the District of Columbia not conflicting with existing laws, as would best afford safety and convenience to the public, and they would also be authorized to prescribe fees for the issuing of licenses and for the examination of electrical wiring, machinery, and appliances; it would also be the duty of the board to examine all applicants for licenses as electrical contractors and report the results to the commissioners. Before obtaining a license a contractor would be expected to file in the office of the commissioners a bond with satisfactory sureties in the sum of $2,000, for the faithful performance of all work which he might undertake, so that it would be in conformity with the requirements of the commissioners. Such applicants would not be less than 21 years of age, and the term "electrical contractor" would include all persons putting in place wiring and apparatus necessary for the production and utilization of electrical current for lighting, heating or for power. The fee for a license as an electrical contractor would be $5 per annum.

A further provision is to the effect that any person who shall knowingly employ an electrical contractor who has not been regularly licensed would be subject to punishment by a fine of not less than $5 nor more than $100 and in default of payment shall be confined in the workhouse for a period not exceeding six months. Any persons engaged in the business without a license shall be subject to a fine of not less than $5 for each and

every offense, or by imprisonment for not exceeding one month.

The commissioners would be authorized to appoint an electrical engineer at a salary of $2,500 per annum, to be an expert electrician possessing a thorough knowledge of the most improved methods for the production, use, and control of electricity, and with the necessary executive ability to satisfactorily fulfill the requirements of his office. The assistant would receive $2,000 per annum; two electrical inspectors would also be appointed at salaries of $1,200.

It would be unlawful for any person, company, or corporation generating current for electric light, heat or power in the District to connect its system and furnish current for electrical purposes to any building or premises, the wiring of which shall not have been inspected by the chief inspector of electrical work. The bill is very full in all its provisions for accomplishing the purpose in view.

* * *

To Analyze Coal. The Secretary of the Treasury has asked for an appropriation of $30,000 to be used at the Louisiana Purchase Exposition under the supervision of the Director of the U. S. Geological Survey, for the purpose of analyzing and testing coals and lignites of the United States, in order to determine their fuel values and the most economic method for their utilization for different purposes; this is along a line of work and investigation that has been given consideration for some time past by the Geological Survey.

In the tests which it is proposed to make at the Louisiana Exposition those for actual fuel values will be made in connection with a battery of six 100 hp. boilers, used for the purpose of furnishing power to the indoor and outdoor exhibits of the mining department. All of the coal used in making these tests will be carefully weighed before being fired into the furnaces, and the amount of steam developed and the power utilized carefully ascertained through a uniform period of time and under uniform and actual working conditions. The coal so used will be carefully sampled, so as to obtain an average representative specimen for chemical analysis and physical examination, and this specimen will be sent to the Survey laboratories in Washington for this purpose.

The coking qualities of the samples furnished will be tested in a plant of ten Otto-Hoffman by-product recovery ovens, whereby not only the yield and quality of the coke produced will be ascertained, but also the amount of by-product obtainable from each kind of fuel. These by-products will include gas, coal tar and ammonia. Of most vital importance in connection with these series of tests will be the ascertaining of the amount of creosoting oils which may be obtained from the coal-tar products. The demand for creosoting oils in the treatment of railway ties, telegraph poles and other wood exposed to the combined action of air and moisture is of vital importance in the development of railway construction in the United States at the present time.

All the machinery and lignite materials to be used in making these tests are to be furnished free of all expense to the Government.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

"Cloudborn electric wavelets to encircle the globe" is Mr. Nikola Tesla's latest dream, and he says humanity will be like an antheap stirred up with a stick —"when his first plant is inaugurated."

As was to have been expected a representative of the Brooklyn Rapid Transit Company, at a hearing before the Railroad Committee of the Assembly in Albany, N. Y., protested against the passage of the third rail protection bill, referred to editorially a short time ago by ELECTRICITY. The representative declared that the company was ready to accept any practicable plan of protecting the lives of its employes and passengers, but affirmed that no invention had yet been made which would guard against the danger or would not in point of fact increase it. The gentleman in question is to a certain extent right. There is no scheme that a railroad company could adopt to lessen or eliminate the danger of the third rail *that would not cost money.*

It was announced Friday by the General Electric Company that the annual meeting of the directors of the company will be held in Schenectady, N. Y., on May 10, at noon, and there will be a meeting of the stockholders for the purpose of authorizing an increase of $3,325,000 in the capital stock. It was also given out that E. W. Rice, Jr., has been elected a director in the place of the late William C. Whitney.

Mr. James I. Ayer, chairman of the Committee on Relations with Kindred Organizations of the National Electric Light Association, announces that arrangements have been made by which the association will have permanent headquarters at the St. Louis World's Fair, consisting of a railed inclosure furnished with chairs, a convenient desk, stationery, etc., for the use of its members.

It is officially announced that the directors of the Cunard Line have decided to adopt turbine engines for the new steamers to be built under agreement with the British Government.

Sixteen cancer patients were recently treated with radium in the London Hospital, but the only favorable result has been the cessation of pain in some cases, while in others the patients complain of an increase in the pain. The experiments have stopped.

Mayor McClellan on Saturday last officially opened the new garbage crematory at the foot of West 47th street, New York. It is claimed that by the establishment of crematories the city saved $67,000 a year. Waste paper, boots, shoes, etc., are separated from the garbage and sold at a profit. The rest of the refuse is burned in furnaces beneath a plant of boilers which furnish power sufficient to operate 3,000 16-cp. incandescent lights.

The city of Pittsburg, Pa., "fathers" are discussing the advisability of having the local water supply treated electrically with a view to killing any disease germs.

Installation work is being pushed in the Palace of Electricity at St. Louis. The largest single shipment that has been placed consists of four carloads of exhibits from Germany. They are being installed in the northeast corner of the building and will include a very comprehensive electro-chemical display, as well as electrical apparatus by the best German makers. Nearly all of Germany's exhibit material for Chief Goldsborough's department is now in the building and the installation work is progressing rapidly.

The value of special franchises held by public service corporations in New York City is fixed by the State Board of Tax Commissioners at $251,521,450. This is $16,163,728 more than the total valuation for 1903.

The Signal Corps of the Army is now communicating daily by wireless telegraphy between Forts Schuyler and Wright, New York, a distance of 97 miles. The speed transmission varies from 10 to 30 words a minute, according to varying conditions. Similar apparatus will be installed at Nome and St. Michael, Alaska, as soon as weather conditions permit. The distance between these two places is 107 miles.

PECULIAR EXPLOSION OF WATER TUBE BOILERS.

BY JOHN C. HIGDON, M.E.

There occurred in St. Louis, on December 21st last, a most singular and destructive explosion of water-tube boilers.

That a genuine explosion took place, is evidenced by the photographs taken by the writer on the morning after the explosion, which occurred at about 5 o'clock P.M.

The views, Figs. 1, 2, 3, 4 and 5, show the enormous force exerted by the explosion, the same having spread apart the water-legs and pulled out the ends of nearly all the tubes, and the latter were thrown like toothpicks all over the place.

Fig. 1 shows the location of the boiler-room swept completely clean.

Fig. 4 shows several shells leaning against cars, where they were thrown and lodged fully 100 feet from their places, the water-legs being torn off at one or both ends of the shells. In one instance (Fig. 5), a water-leg weighing over a ton was thrown and lodged on top of a car standing in the car-sheds over 400 feet away.

FIG. 1.

Fig. 2 shows the rear end of one shell with its water-leg attached. The small pipe is the blow-off pipe, not the feed-water pipe, the latter having been attached to the front end of the shell.

Fig. 3 exhibits the back ends of a pair of the shells, the force having been so enormous as to have sheared and torn out the rivets.

The exploded boilers were quite old and had been subjected to over 12 years' continuous hard usage in the plant of the St. Louis Transit Company, having been erected in 1891 by the Heine Safety Boiler Company.

Seven boilers exploded, the same having been located at one end of a battery, of 23, all connected to a single steam header.

Seven men were killed, most of whom were colored firemen. Property to the amount of $50,000 was also destroyed.

There were fortunately very few persons employed at the plant, or the loss of life would have been much greater, and especially if the boilers had been located in the basement of one of our city's sky-scrapers.

FIG. 2.

The coroner's jury held as follows:

"Either the boilers and apparatus connected therewith were not in good condition, or there was incompetency or negligence in running the plant."

No inspection had been made by the St. Louis boiler inspector since February, 1903, almost a year ago, and so no blame could be laid at his door, as the law requires inspection but once a year.

But it seems there had been a recent inspection by one of the Casualty Companies, and the Transit Company's chief engineer, who was on duty at the time the explosion occurred, testified, when asked what kind of an inspection had been made a short time before, that he and the inspector "walked up and down the boiler-room and he looked at the water column which shows the level of water in the boilers."

FIG. 3.

Needless to say that if such action constituted an "inspection;" there might as well not be any made in the future, because all real, live engineers know that the water column connections frequently become stopped with mud and scale and render the glass-gauge and try-cocks unreliable, even though plenty of water be shown there.

Undoubtedly there is much room for reform in boiler inspections, and as the feed-water pipes were found to be plugged with scale on the exploded boilers, we suggest that inspections hereafter, particularly on water-tube boilers, include taking down the feed-pipes.

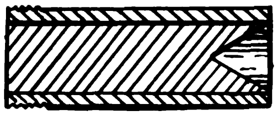
A sketch of the two feed-water nipples of one of the boilers is shown. One was found entirely plugged up with hard scale, so that not a drop of water could enter, and the other had but a $\frac{1}{8}$ inch passage, utterly inadequate to supply so large a boiler, the same being rated at 250 hp.

FIG. 4.

There were no fusible plugs in the boilers.

This would seem to have been a clear case of low water, in at least one of the boilers, as the feed pipes were badly plugged with scale, and the engineer testified, that he depended entirely upon the glass-water gauge to indicate the amount of water in the boiler. He also testified that just before the explosion one of the boilers had been cleaned and supposedly filled with water, and fired up; and the probability is that the tubes weie only partially filled with water owing to the plugged feed-pipes, and when fire was applied the steam accumulated to an enormous pressure, as the header-valve was also perhaps closed; and there is good evidence that a number of the safety-valves were so badly "stuck" with scale and corrosion that they could not possi-

bly have opened at anything under 500 pounds to the square inch. There was also evidence that a new header had just



Left Nipple Fully Stopped.

been finished and connected to the boilers, so that it is very likely that the main steam valve was closed, cutting off the seven exploded boilers from the balance of the battery.

It is well known that the superheated water contained in a boiler under pressure will, when suddenly relieved of pressure, exert an energy per cubic foot equal to that exerted by one pound of black gun powder.. A reasonable explanation of such action lies in the fact that the water in a boiler has an enormous amount of heat stored within it; or, in other words, the reservoir or store-house for the latent heat, for the word "latent" means "stored."

Even supposing that boiler to have contained only a barrel of water, the same

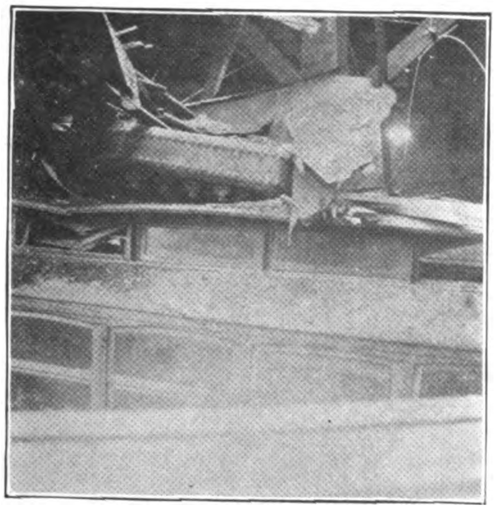


FIG. 5.

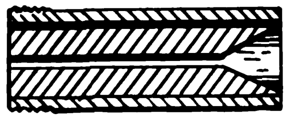
would generate a sufficient energy to tear any boiler to pieces when subjected to over-pressure and low water.

Many have wondered why the tubes alone did not burst, as usually occurs in explosions in water-tube boilers. In the present case, the tubes did not burst, but the water-legs were stripped off of the ends of the tubes, leaving the latter free.

The evidence points to the probability that but a single boiler caused the explosion, it having been suddenly relieved of pressure by a broken steam-header, or perhaps by the giving away of a number of overheated tubes during low water, with the safety-valve out of order and the header-valve closed; and this would be sufficient to break the header, and thereby release the steam contained in the remaining six boilers, which would have the effect of causing the superheated water contained in them to at once flash into a



Right Nipple Almost Stopped.

great volume of steam, which no boiler could possibly withstand.

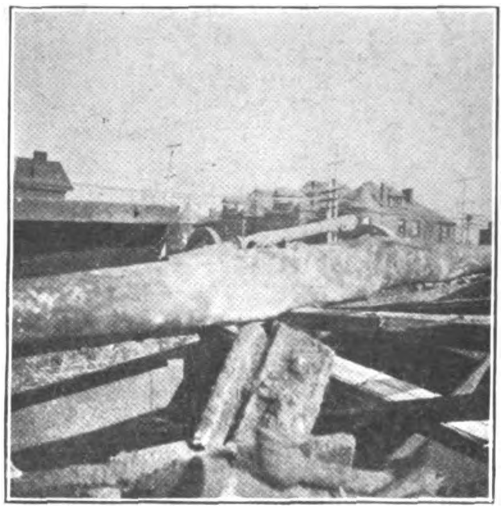


FIG. 6.

It was stated by some of the witnesses that the boilers exploded one at a time, and that seven consecutive explosions were heard.

Fig. 6 shows one of the tubes which had evidently been badly overheated and could only have been caused by low water.

Figs. 7 and 8 show the same tube at the top of a large pile of tubes. The ends of

FIG. 7.

these tubes bear clear evidence that they were stripped from the holes in the water legs.

The occurrence of the above described explosion should not at all detract from the popularity of water-tube boilers, as it has been clearly shown that the explosion occurred through no defect in construction. It would have required something like 1,000 pounds per square inch to have torn the shells of these boilers in the manner indicated in Fig. 2, and at other points observed by the writer while taking the photographs.

The writer therefore has no hesitancy in stating that, in his opinion, the Babcock & Wilcox, the Sterling, or any other water-tube boiler would have gone to pieces under like circumstances.

Since the foregoing was written the St. Louis Board of Engineers have made their report, as required by law, and they substantially affirm every statement, and even go farther in their condemnation of the street railway company's superintendent of motive power, Mr. Cook, who is not a licensed engineer, and yet is allowed under the present law to give orders to many licensed men under him. The board has revoked the license of the engineer who was on duty at the time of the explosion, on the ground of negligence or incompetency.

Right here is seen a fatal defect in the present law, and no time should be lost

FIG. 8.

in remedying it. No unlicensed man should be permitted to give orders to licensed engineers, even if the former be the employer.

The board report in part as follows:

"A test of the safety valves showed they required from 142 to 170 pounds to the square inch to force them open, when the law allowed them but 125 pounds.

"There has never been a boiler devised which cannot be exploded by an incompetent or careless engineer.

"A water-tube boiler in the hands of such an engineer is no safer than a fire-tube boiler."

Stone & Webster, Boston, have completed the consolidation of the railway and lighting properties in Ponce, Porto Rico, and all are now being operated under their management.

DASH POTS FOR CORLISS ENGINES.

ARTICLE V.

BY W. H. WAKEMAN.

Fig. 10 illustrates another dash pot in which air circulates from one part to another, instead of being drawn in and discharged in the usual way. It is much more complicated than any of the others

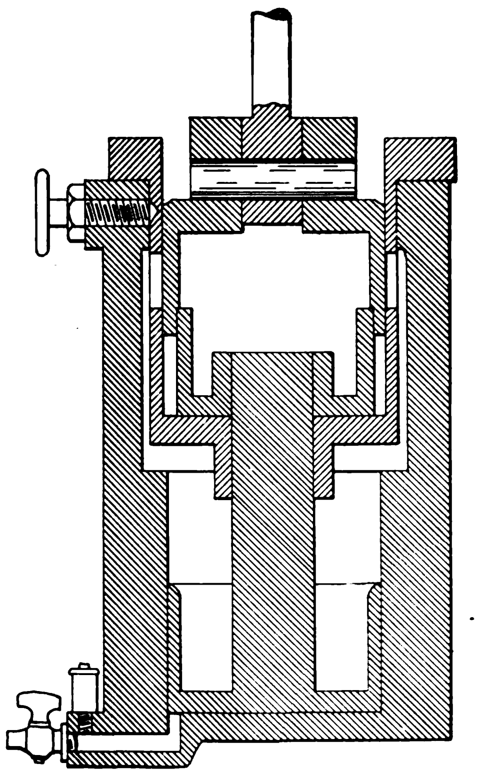

FIG. 10.

shown, yet it works smoothly and well. The passages are partly shown in the cut, and these are sufficient to give a general

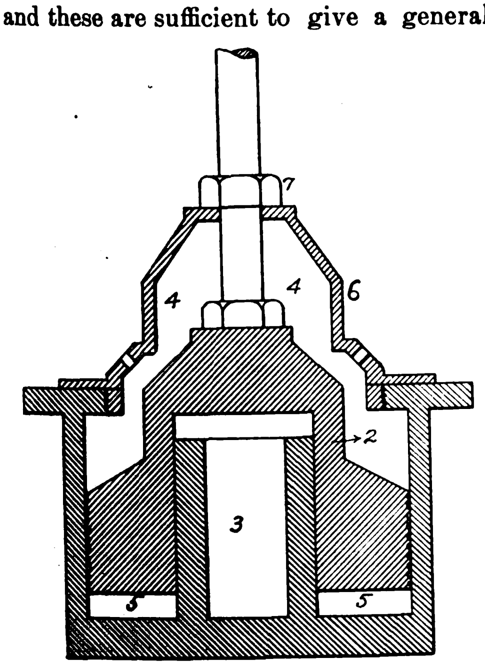

FIG. 11.

idea of the plan of operation, although not explained in detail as in former cases

The pet cock at the bottom is not for general use, but for the purpose of draining out oil when necessary. Dash pots require but little lubrication as they work vertically, therefore the friction is small.

Fig. 11 is another type that discharges no air. The piston, 2, is in about the middle of its stroke, therefore a partial vacuum exists in the chamber, 3 Air is now passing from 4 and 4 to 5 and 5 by means of the passages between the outer edge of piston at its greater diameter, and the cylinder walls. When the plunger reaches its limit of travel there will be a greater degree of vacuum in 3, or in other words, the air pressure in 3 will be reduced still lower.

When the plunger descends it cushions on air in 5 which is compressed and driven upward into 4. The operation is continued indefinitely.

The whole cap 6 may be unscrewed by applying a wrench to the nut, 7, as it is not connected to the dash pot rod. This rod is fastened rigidly to the plunger.

The first Corliss engine that I was placed in charge of was fitted with dash pots located beneath the engine room floor, in a little dark and dirty place where a man could not stand erect. The light of day never penetrated to it, and the plungers were so placed that it was both difficult and dangerous to oil them thoroughly while in motion.

My second Corliss engine resembled the first in this respect, and was unsatisfactory accordingly, as it was necessary to go down a short ladder and get into these disagreeable quarters every time that the devices required attention.

One day while examining one of these dash pots by the light of a candle it was brought too near some small pieces of waste, or something of that kind saturated with oil, and in an instant a lively blaze was started. As the engine room floor was only about one foot above this spot, and oil was actually dripping down from it, the prospect for a destructive fire seemed good, but some vigorous work in

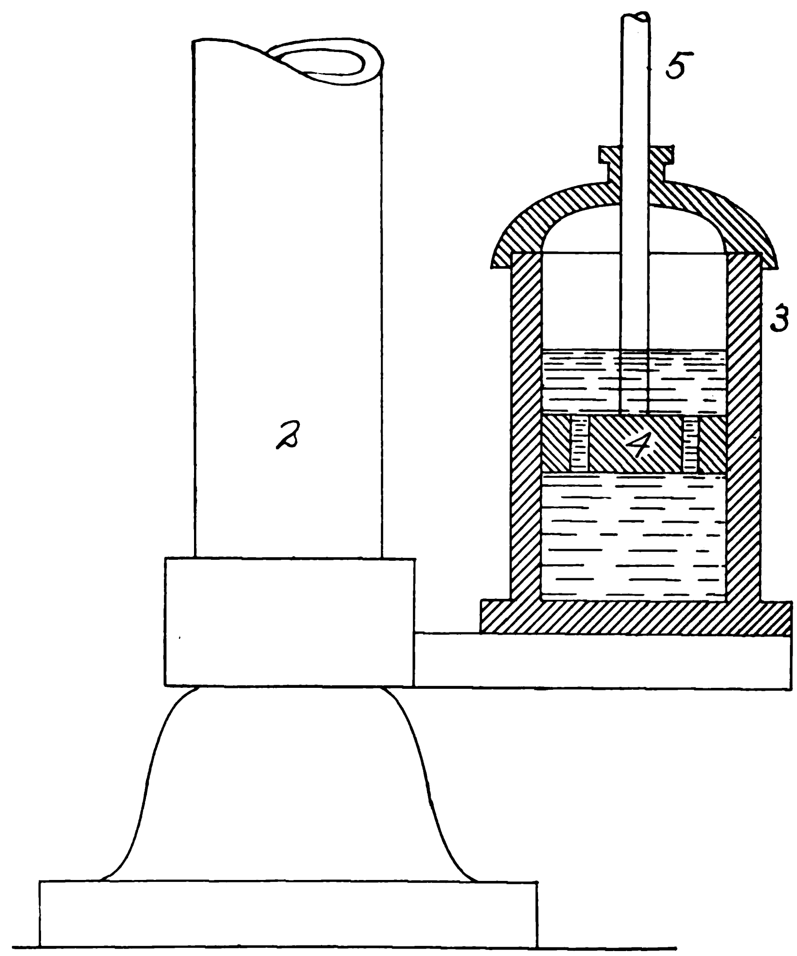

FIG. 12.

self defense, disposed of the fire, and the danger was past. This is the reason for my strong objections to dash pots placed under the floor.

Another objection is based on the fact that unless the rod of a dash pot so located is unusually heavy, it will constantly vibrate or tremble, and this does not appear right, as everything should be solid about an engine.

The improvement which ranks next along this line, is the plan of placing dash pots on a level with the floor. While this is a move in the right direction, it still calls for a long rod, especially where the cylinder is large.

The next change noted is placing them on the cylinder feet, which brings them

about 1 foot above the floor. This makes them accessible for oiling and adjusting, and allows the use of a comparatively short rod.

As a rule we go to extremes in all things if given time enough, and this matter is no exception to the general rule, for the next move was to place them just below the steam valve stems, but above the exhaust valve connections.

No special point is gained by this change, and when oiling the valve gear of such an engine in motion there seems to be enough machinery about the wrist plate, without bringing dash pots into the collection.

While a rod that is too long vibrates and is not satisfactory, one that is too short does not operate at right angles to the bore of the cylinder, hence it tends to draw the plunger away from its proper course. Placing the dash pot on a cylinder foot seems to be a satisfactory medium between the two extremes that gives the best results.

The principle objection to the Corliss engine is due to the fact that the wrist plate with its connections seems complicated to the casual observer, and the dash pots working quietly and easily, or noisily and hard, as the case may be, add much to this objection, especially with a compound or triple expansion engine, as more than one cylinder is in use. The fact in the case is that the Corliss engine is one of the most simple and easily understood in use at the present day, when we consider the results secured by it, and the dash pots are not so objectionable as they appear, for when once properly adjusted they need no further attention for many weeks, except to oil them once a day.

Dash pots are not used on Corliss engines exclusively, as the title of these articles might imply. The idea was to consider those that are so used, consequently the title is appropriate.

Wherever a disengaging cut-off valve gear is used a dash pot of some kind becomes necessary, to gradually arrest the motion of the moving parts, preventing unnecessary wear and noise.

Sometimes a dash pot is attached to the governor of a Corliss engine to prevent the balls from suddenly changing their position, and other engines are also fitted with the same device. It is sometimes called a "gag pot," but it is one form of dash pot nevertheless. The operation of it will be understood by an examination of Fig. 12.

The body of the governor is shown at 2 to which is secured a bracket on which the dash pot, 3, stands; 4 is a loose fitting plunger with several holes bored through it, and 5 is the dash pot rod. The pot is about two-thirds full of oil which circulates through the plunger as the governor balls cause it to rise and fall by means of the rod, 5.

If the balls tend to fluctuate in their path, the dash pot plunger counteracts this tendency, as it cannot travel faster than the oil allows it to, as it changes from one side to the other. There are two ways of regulating this rate of travel, one of which is to vary the capacity of the holes, and the other is to use a thick or a thin oil, according to conditions.

Suppose that six holes ¼ inch in diameter are bored in the plunger, each of which is tapped and a screw fitted into it. If all of the screws are left in place the plunger will move very slowly, even if filled with kerosene oil. Removing one of the screws may make it right, or more may have to come out, but the capacity of the holes is great enough to allow a rapid movement.

If it moves too easily with kerosene, substitute engine oil, and if this is too thin use cylinder oil.

A certain engineer in charge of a large Corliss engine, found that after running it several months, it suddenly failed to maintain a steady speed, as the governor balls traveled from their highest to their lowest limit rapidly, and it took him several days to discover the cause.

In the meantime the mill employes were all disgusted on account of the varying speed, which made it impossible to do good work. After much worry and annoyance the engineer discovered that there was a dash pot on his governor, and that there was no oil in it. A quart of engine oil was a remedy easily applied. If he had read a description of this appliance as here given, it would have saved him much trouble.

THE ELECTRO MECHANICAL COMPOUNDING OF GENERATORS.*

An ideal regulator should come into operation at the same instant as the changes of load for which it is to compensate, so that the necessary additional driving power may be supplied as required. If the steam engine or turbine-driven dynamo is a compound wound one, the voltage will be constant at all loads, but if shunt wound, the excitation must be altered to suit each load change, and if this alteration is accomplished at the same time as the change in driving power, no voltage variation will occur. The governors employed up to the present on prime movers driving dynamos have the essential drawback that a change of speed must actually occur before they can come into action. It is obvious that in such a case a variation in dynamo voltage must occur, due partly to this change in speed and partly to the strictly electrical change. The regulation, in fact, is carried out at present by letting the governor do its share and then adjusting the excitation by means of a variable resistance.

Recently Mr. Routin, of Lyon, has succeeded in producing regulators which comply with the ideal conditions stated above. It is clear that for every load on the dynamo a particular value of the excitation, as well as a particular amount of steam admission, are necessary, and this naturally suggests that both excitation and admission should be controlled by the same piece of apparatus. Every change of load is followed by a voltage change, partly due to ohmic drop and armature reaction—i. e., electrical causes—and

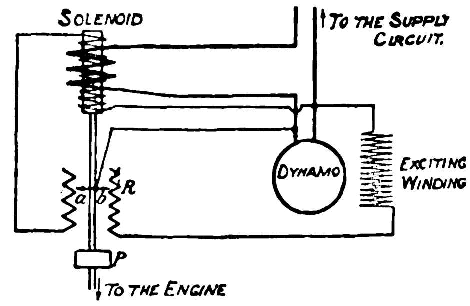

FIG. 1.

partly due to speed changes—i. e., mechanical causes. The changes due to electrical causes can be counteracted instantly, but those due to mechanical causes are not so quickly dealt with, as they are subject to the law of inertia. Good regulation requires that the steam admission should be increased and the excitation be strengthened at the same time, whenever either the current increases, the voltage drops, or the speed drops, and vice versa. An apparatus in which the differential action of the current and the voltage is employed may, therefore, be expected to give good results. With Routin's regulator the action may be compared to what would occur if, each time a lamp were switched on, the engineer in charge took the trouble to alter both the steam admission and the excitation of the machines.

The apparatus consists, in principle, of an iron core acted upon by the difference in ampere-turns of a main circuit coil and a shunt coil connected to the terminals (see Fig. 1). The main coil carries the current generated by the machine at each instant. The shunt coil, which is con-

*Translation in abstract of an article by F. Broek in "Elektrotechnische Zeitschrift, Jan. 14, 1904. From the "Electrical Engineer," London.

nected in opposition to the main coil, is fed from the generator terminals in series with a regulating resistance, the amount of which is determined by the position of the sliding contact, *a*. At the same time a second sliding contact, *b*, moves over the resistance, R, and alters the excitation of the machine. The dimensions of the two coils are chosen so that the shunt coil normally overpowers the main coil. The iron core of the solenoid is directly connected to the admission gear of the engine and carries a weight, P, producing a permanent downward pull. When the iron core moves downwards the admission is increased, and when it moves upwards increased. Suppose that the speed, voltage, and steam admission are normal, and that the weight, P, is held in a certain definite position by the differential action of the windings. Suppose also that the voltage of the dynamo keeps constant at all loads—i. e., the machine is compound wound. Then any increase in load will correspond to an exactly proportional increase in the current delivered by the machine, and the ampere-turns of the main coil will increase, so that the overpowering action of the shunt coil will be correspondingly diminished. This will lead to a fall in the iron core, and this produces an increase in steam admission. At the same time, contact *a* will have moved down and reduced the resistance in the shunt coil. As soon as the shunt coil increase becomes equal to the main increase in the opposite direction, the iron core will come to rest.

If the dynamo is a shunt-wound one, it is only necessary to make the change of position of contact *b* alter the dynamo exciting current sufficiently to maintain the normal voltage. In the case of a short circuit occurring, the main coil ampere-turns will reach an excessively high value, and will then overpower the shunt coil, reverse the polarity of the iron core, and cause it to rise, thus closing the admission valve. Should a main fuse blow, only the shunt coil on the solenoid will remain in action, and this again will effect the closing of the valve. Should the speed of the machine be altered, due to any external cause, such as a change of head (in the case of turbine-driven sets), etc., the currents in both windings of the solenoid alter proportionately, and their difference becomes greater or smaller according as to whether the speed had increased or diminished. In the former case, the iron core is drawn further up, and so closes the admission valve, whilst in the latter case the reverse occurs. The contact on the excitation resistance can be adjusted by hand whilst running, and the degree of compounding can, therefore, be adjusted at will. If both contacts are altered together by hand, the loading of the machine can be adjusted as required, so that when several machines are running in parallel the load on any one of them can be varied in any way desired.

ELECTRICAL STATION PRACTICE.

ARTICLE XXX.

BY W. H. RADCLIFFE.

In an electrical station where accumulators are used for helping out the generators during periods of heavy load they are usually connected so that they will be automatically charged by these same generators when the load is light.

The general connections between the accumulators, generators and distributing circuit is given in Fig. 29. The number of accumulators at *a* should be such that the total normal voltage developed by them will be practically the same as the rated voltage of the generator or genertors at *b*. The connections in Fig. 29 show the accumulators to be in multiple with the generator across the distributing circuit. When the load on the distributing circuit is such that the generator *b* is developing its normal current, the accumulators will neither deliver current to the line nor take current from the generator. If the load increases above this amount the voltage of the generator will drop, unless the machine be compound wound, in which case the voltage will increase slightly, but all the current in excess of the capacity of the generator will be supplied by the accumulators which will then be discharging into the distributing circuit. On the other hand when the load on the distributing circuit is light, the excessive voltage of the generator over that of the accumulators will act in charging the latter.

During the discharge of the accumulators the specific gravity of the electrolyte and the voltage of the battery will fall. If the value of the specific gravity becomes less than 1.20 a portion of the electrolyte should be siphoned off and a fresh quantity of solution having a higher specific gravity added. Owing to injury to the plates concentrated acid must never be added to the electrolyte in a battery without first being diluted. As to the drop in voltage, this will usually be gradual, but should never be allowed to fall below 1.7 volts per accumulator, since after this point is reached the pressure will drop more rapidly and the plates are then liable to sustain injury. Voltmeter readings of the individual accumulators and also of the voltage across all of them must therefore be made from time to time, the former readings to determine whether each accumulator is properly performing its duty and the latter readings to show how much further the discharging process may yet be continued. Of these measurements, the individual readings will be low and a direct current voltmeter having a capacity of 5 volts will be plenty large enough. For the total voltage, however, a direct current voltmeter having a capacity of 150 or 750 volts may be necessary, so that it is obvious two instruments or an instrument having a high-pressure and a low-pressure scale will be required for the purpose.

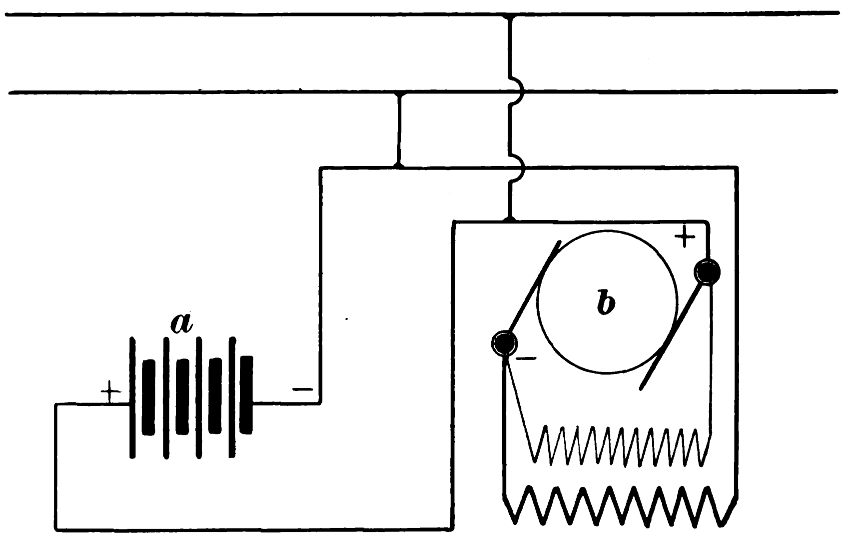

FIG 29.

In modern types of accumulators the normal rate of discharge should not ordinarily exceed 8 amperes per square foot of positive plate surface, although the advice of the manufacturers should be obtained and followed in any given case when possible. It is not advisable to discharge a storage battery beyond the point where 25 per cent. of the original charge remains. This matter, however, will properly adjust itself if the voltage limitation previously mentioned be not exceeded.

In the management of a storage battery plant may be found a practical verification of the quotation "Eternal vigilance is the price of safety." The defects that usually occur in the battery may, if discovered in time, be generally remedied by properly treating the affected parts. The most common of the troubles that may be anticipated is the sulphating of the plates. By this is meant the formation of a deposit of white sulphate upon the plates, caused usually by a too rapid rate or a too slow rate of discharge, or by the electrolyte being too weak or too strong. Sulphating, if allowed to continue, will cause the active material of the plates to become loosened and fall out; it may also cause internal short-circuits between the plates, and if not remedied will eventually decay the lead plates or grids. The remedy for accumulators in this condition is to charge and discharge them at a slow rate, although if the sulphating is very far advanced it may be necessary to scrape the deposits off the plates by means of a stick and then give them a thorough washing in the battery solution. Under no circumstances should metal be used for the scraping process, nor should water be used in washing the plates after being scraped. As soon as the plates are washed they must immediately be returned to the jars or tanks containing the electrolyte, which latter should perfectly be renewed at this time.

In some accumulators separators are not employed between the plates, and whenever such a battery is overcharged there is always liable to be more or less trouble caused by the twisting or buckling of the plates. This defect may be prevented by employing wood, rubber or glass separators between the plates, or by a slow rate of charging and discharging as recommended for sulphated plates.

The life of a storage battery may be taken as that of the positive plates, and under average conditions in electrical station practice this is approximately three or four years. The life of the negative plates is always longer than that of the positive plates, but both positive and negative plates suffer deterioration and in wearing leave a deposit in the bottom of the jars or tanks. In order that this deposit may not readily come in contact with the lower parts of the plates and thus short-circuit them, they are supported by lugs or ribs so as to leave a space in which this deposit may collect between the plates and the bottom of the containing vessel. It is necessary, however, to clean out this deposit from time to time in order to avoid internal short-circuits as previously mentioned. Such foreign substances as dirt, nails, bolts, etc., must be kept away from the tops of the accumulators, else they fall in unnoticed and ruin the battery before the trouble has been located. Broken separators may also lead to internal short-circuits, although this defect is not of very common occurrence. A good plan to follow and one which will often aid in the prevention of trouble consists in numbering the accumulators and keeping a record of each one; then, when the battery as a whole is not giving satisfactory results, the fault may usually be located at once by examining those accumulators whose records are below the average.

Passing the charging current through the battery in the wrong direction will seriously injure the plates, and may possibly destroy them entirely; it is therefore necessary to make certain that the like poles of the charging circuit and of the battery are connected together. Various forms of pole testers are on the market for accomplishing this purpose, but after the first test, which can be made with a voltmeter, the wiring may be so arranged that there need be no confusion. In making this test with the voltmeter it should first be connected across the charging circuit, and when the pointer of the voltmeter is deflected in the proper direction over the scale the wire connected to the left-hand binding post should be marked. A similar test with the voltmeter is then made across the two terminals of the entire battery installation, and when the wires are so connected to the meter that a deflection in the same direction as before is obtained, the wire joined to the left-hand binding post of the voltmeter is of the same polarity as that of the wire of the charging circuit previously marked. These two wires must therefore be connected together in charging, and as the remaining wires must necessarily be of the same polarity they also may be connected together.

In describing the chemical reactions taking place during the charging process it will be remembered that considerable hydrogen gas was generated. This gas is explosive, and care must be taken, particularly when the battery is inclosed within a poorly ventilated space, not to bring a lighted match or other exposed flame near the cells or accumulators. For inspecting the working parts of a battery, a special form of incandescent lamp on the market, which is provided with a flat bulb and wired to a lighting circuit with a flexible wire conductor, will be found very convenient and effective, when inserted in the cells, to light up the dark passages between the plates.

When a storage battery is used only occasionally, or when it is to be out of service for several months or longer, special rules must be followed or the battery will become worthless in the meanwhile. During the time the accumulators are inactive they will gradually become discharged on account of certain local losses constantly going on within them. The normal capacity of the latter, under such conditions, cannot be obtained by simply recharging, it being necessary to first entirely discharge the accumulators and then give them a fresh charge. This should be done weekly even though the accumulators are used several times during each week, and if a single charge can be given them this often, no serious results will ensue even though the battery be left unused for a much longer period. If, however, it be desired to leave them without any attention whatsoever, this may be done by first giving them a full charge and then siphoning off the solution. The siphoning can be best done with a three-eighths of an inch red india-rubber tube; this should be filled with the electrolyte by dipping it into a vessel containing the solution and then pinching the ends of the tube so that the electrolyte will not run out until one end of the tube is inserted in the battery jar or tank, and the other end is placed in an empty vessel at a lower level. The ends may then be allowed to open, whereupon the solution will run out of its own accord. The tube should never be sucked to start the process, for the solution is both poisonous and corrosive, and if by accident any of it be drawn into the mouth the results would be serious.

After the solution has been siphoned from the accumulators, the plates may be taken out and placed in water so that all of the acid will be removed from them, after which they should be withdrawn and allowed to dry. The positive plates should then be separated from the negative plates, the former packed away, and the latter again placed in electrolyte having a density from 1.275 to 1.300 and soaked for three or four hours. After being once more rinsed and dried, they two are ready to be packed away. The wooden separators are generally useless after being in service and may as well be thrown away, but the rubber separators should be washed in water and preserved.

The arrangement of the accumulators within the station forms an important factor in their operation and should therefore merit considerable attention. If they are placed too closely together, or if they stand directly upon the floor, the electrolyte which naturally creeps more

or less will form a conducting film between the jars or tanks resulting in a leakage of the current. Such leakage may discharge the battery without the knowledge of the attendant. Moisture of any kind outside of the accumulators must consequently be eliminated as far as possible by providing the battery room with sufficient ventilation, and also by allowing some space between each of the cells and between the cells and the floor. Glass or porcelain insulators may advantageously be used for supports, but upon these boards should be placed, so that the weight of the battery is more evenly distributed upon the insulators and they are therefore less liable to break than would be the case were each accumulator placed upon its respective insulators. In all cases the boards should be varnished to maintain a high insulation resistance. The creeping of the electrolyte may be avoided by applying to the rim of each of the jars or tanks a coating of paraffin about an inch wide on their inner sides; in some cases insulators are used in which oil may be placed, the oil offering an obstruction to the creeping of the electrolyte and thus prevents leakage.

In placing the accumulators in position it must also be remembered that each of them must be located so as to afford accessibility in case of examination or repairs. If the necessary amount of floor space is available they should all be mounted upon supports resting upon the floor; if, however, the floor space is limited they may be arranged in tiers one above the other. When the accumulators are small and can readily be placed in position by hand there is not much objection to this method if ample space be allowed between them, but when the accumulators are large, requiring a tackle or a traveling crane to place them in position, it is evident there is much to be said against it. In order that the examination and repairs previously referred to may be easily accomplished, it is necessary that the storage battery room be well lighted through windows by day and by means of incandescent lamps by night. Care must be taken, however, to prevent the rays of the sun shining directly upon any part of the accumulators. It may be mentioned in this connection that when the batteries are provided with glass jars, inspections can more quickly be made than when metal, rubber or wooden tanks are employed.

The floor of the battery room should be constructed of some material unaffected by sulphuric acid; concrete or brick may therefore be used, but wood should not be employed. In order that the floor may easily be cleaned with water from time to time, it should incline slightly toward a drain. If at all possible, the battery room should be separated by a partition, or otherwise, from other parts of the station containing machinery; this is necessary on account of the corrosive effect which sulphuric acid fumes have upon unprotected iron.

Storage battery attendants are subjected to certain inconveniences, and in fact dangers, if certain rules are not carefully observed. The more important of these rules will conclude the discussion of this subject. Smoking must not be indulged in by those engaged in the battery room; in fact, any exposed flame or spark will as previously stated ignite the hydrogen gas and cause an explosion of more or less violence. Sore hands frequently result from contact with the electrolyte, but if they be dipped from time to time in a supersaturated solution of washing soda and water, the injurious effect will be counteracted. Particularly destructive is the battery solution on clothing, but a small application of ammonia fortis to the affected parts will usually remedy the matter by neutralizing the acid.

STANDARD PRACTICE IN THE USE OF ALTERNATING CURRENT ELECTRICAL APPARATUS.*

BY J. J. GIBSON.

In the whole range of the arts the growth of none has been so rapid as that of the electrical. In a space of time so short as to seem miraculous, within a period almost as short as 15 years, there has been a complete growth from "infancy" to maturity, from the experimental to the practical.

The characteristics of electrical appliances in the commercial arts can be said to-day to have settled into fixed lines of practice. Advance there will be, but it will proceed along lines already clearly defined. Inventions and discoveries of far-reaching value are to be expected as time goes on, but none is conceivable of a nature so revolutionary in character as to make any essential change in practice which is at present considered standard.

During the 15 years just passed every electrical device and system has passed through the fiery furnace of actual trial, and this process of refinement has thrown out the dross. We have left, therefore, only those things which are fittest; first and foremost those things which are simple, for in simplicity lies every advantage and economy.

Alternating current apparatus was first put on the market in this country at a time which marked the beginning of a period or great electrical development. Its introduction and exploitation may be said to be responsible for that great development. The direct current systems in vogue at that time had reached the limit of their development, and the time was ripe for another system of distribution of power which would permit of a wider scope of action. In extending the old direct current systems it was found that the cost of copper put into feeder circuits was growing to a point which was almost prohibitive.

As the amount of copper for the transmission of a given amount of power with a given loss is inversely proportional to the voltage used, alternating current generators were put forward because a higher voltage could be generated without commutating the current. They were not used prior to that time, perhaps because the pioneers in the art knew how to use nothing but direct current, since previous to machines they had drawn all of their current from batteries or thermopiles. When they found their machines generated alternating current they devised the commutator in order to turn it into direct current. Excepting direct current, constant current arc machines, whose current capacity is limited to about 10 amperes, the highest voltage at which current of any volume can be successfully commutated is, perhaps, about 600 to 700 volts; not high enough to effect very much saving in copper for transmission in constant potential distribution, and too high for safety.

The first alternators brought out, however, were arranged to give approximately 1,000 or 2,000 volts, and with them was offered the lowering transformer to secure a safe working voltage for entering buildings. The transformer was found to work both ways, that is it could be used to raise as well as lower electrical pressure, and long transmission lines became feasible.

The induction motor was developed and water powers began to be utilized. Rotary converters, turning alternating into direct current, enable traction companies to widen their systems. The resulting development in all lines has been phenomenal and it is likely to be greater still.

While all these things were being worked out, the very apparatus which made them possible was itself in process

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

of development. The old direct current school of electricians objected to alternating current apparatus first, because it appeared to be very complicated. The equation, $C = E \div R$, no longer solved every problem. To-day, while perhaps the theory of alternating currents is still a mystery to the uninitiated, nevertheless, alternating current apparatus is simplicity materialized. While in the state of development, each new device which was brought out used a new frequency, a new voltage, a new combination of phases, a new wrinkle of some kind, only of value to create a possible monopoly if the device were successful, and the result has been a heterogenous mass of apparatus, most of which can now be found in the scrap heap. The process of refinement of actual trial, however, has resulted in the survival of the fittest, just as might have been expected, and the fittest is the simplest.

One tendency clearly discernible in this evolution has been directed toward the elimination of moving contacts in circuits, or the reduction of the number of such contacts to a minimum. The principle carried to the extreme in generators led to the inductor generator with no moving wires of any nature. This type of machine, however, was found to be lacking in other qualities. It has very poor regulation and very much reduced output on power factor load. The result has been the development of the revolving field generator. In this type of machine the moving contacts are reduced to two in number, through which the exciting current is carried to the field coils, which are on the revolving element of the machine. This was not a step backward, for in the main power circuit of such a generator, there are no moving contacts, and what could be more simple than a generator of this character carrying a load of induction motors of the short-circuited secondary type?

We may say that the revolving field generator has become a fixture. In comparatively small machines the revolving armature generator is just as good for both belted and direct connection and it has some advantages. It can be built lighter for the same output. The stationary part of the revolving field machine must be built heavier to prevent collapse of the frame than is required for magnetic conductivity. For machines of equal output the revolving field generator requires larger exciting current than the revolving armature machine. Other things being considered also, the revolving armature machine is more efficient. We may say, therefore, that up to a certain size the revolving armature alternator is also a fixture, provided the voltage and amperes are within certain limits. One thousand amperes can be taken from a collector ring with successful operation, and without excessively expensive collector ring construction. If the current per terminal in any machine is greater than 1,000 amperes, the machine should be of the revolving field type; however, rotary converters are of necessity revolving armature machines and currents as high as 2,000 amperes per collector ring are taken from them. If the voltage desired from the machine is greater than 2,600 to 3,000 volts, the machine should be of the revolving field type.

We may expect to find the revolving armature machine always in use and on the market because the lines of the various manufacturers have been fully and carefully developed, and in sizes up to approximately 200 kw., and for ordinary distributing voltages not exceeding 1,100 to 2,200 volts, the revolving armature machine may be considered the more desirable. It has a higher efficiency than the revolving field machine and takes a smaller exciter. A revolving field machine has the advantage of it only by reason of the fact that there are no moving contacts in the main circuit. As we go to larger sizes and higher voltages the revolving field machine shows more advantages. Voltages such as 6,600 or 11,000 are possible from stationary armature windings, which can be more perfectly insulated than windings which are in the revolving element of the machine.

Alternators are built both separately excited only and compound wound or composite wound. The latter type have series coils on the field poles through which a current is sent after being rectified by a commutator on the shaft of the machine. This rectified current is taken from the secondary of a series transformer, the primary of which is in the main circuit from the armature of the alternator. Large alternators are now built separately excited only with no compounding. Eight per cent. inherent regulation, full load to no load, is standard, and if better regulation than that is desired in operation, varying the field current by changing the field rheostat by hand is resorted to. If composite winding is necessary in a generator, the indirect method of compounding is desirable, in which the compounding current is sent through series field coils on the exciter and not through any field coils in the generator itself. Automatic compounding of alternators gives satisfaction only on non-inductive loads. Automatic compounding devices have been put forward designed to secure proper voltage regulation irrespective of the power factor of the load, but none such has been a success so unqualified as to make its adoption in any way general. Such devices can not, therefore, be called standard practice.

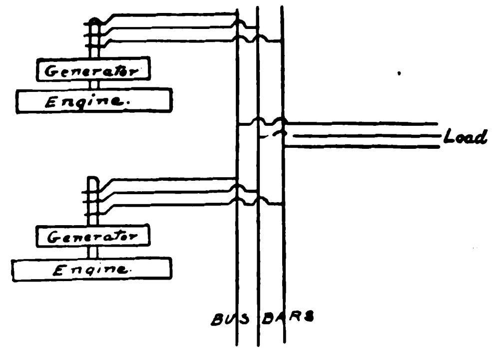

FIG. 1.

Direct connection versus belted connection is not an electrical problem so far as choice of method goes. This is naturally a matter of expense to be justified by the conditions surrounding any given installation. The engine requirements, however, for successful parallel operation of alternating current generators are more severe for direct connected units than for belted. The same considerations apply to the parallel operation of belted units, but belt slip lessens the evil effects of improper engine performance. If we consider, therefore, the case of engine type or direct-coupled alternators in parallel we will be investigating the more important one.

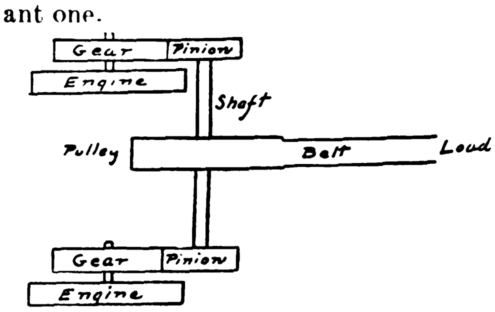

FIG. 2.

There is one way of considering this problem, and that is by means of a mechanical analogy. Let us take two units, each consisting of an engine driving an alternator, and let each alternator be connected to a set of bus-bars to which the load is connected, as shown in Fig. 1. Let us take, on the other hand, two units each consisting of an engine on the shaft of which is a gear. Each gear has its teeth intermeshed with those of a pinion on another shaft common to both pinions. On this shaft there is a pulley belted to the load. Let us imagine that the shaft is somewhat flexible. This arrangement is shown in Fig. 2.

Let us now suppose that the apparatus

in Fig. 2 is in operation. On account of the flexibility of the shaft a slight variation in angular position of the gears at each end is possible, but when such variation exists the elasticity of the shaft tends to draw back to a position where there is no such variation. Suppose one of the engines advanced for some reason. It takes more than its share of the load and a very few degrees of displacement would remove the entire load from the second engine. The governor of the first engine acts to admit more steam, because the engine is being called upon for more power. The governor of engine, Fig 2, immediately acts to cut off steam, because that engine is not being called upon for as much power as it had been delivering, but at the same time the elasticity of the shaft has been acting to pull the engine, Fig. 2, up to speed, and does pull it beyond that point, so it becomes the engine running in advance and all of the conditions are reverses.

You can see how an oscillating action is here set up, like the swinging of a pendulum. If the engine governors happen to have a period of swing, you can see how they would set up an oscillating action between themselves, shifting the load from one engine to the other, on the same principle that a child might "work up" a swing, that is, by first starting the pendulum action and then applying the power at that point of the travel of the swing which would increase its amplitude. If, furthermore, the natural period of swing of the governors corresponds to that of the elastic shaft, everything will combine to assist in swinging the load from one engine to the other.

(*To be continued.*)

Proposals Invited.

The Navy Department, through the Bureau of Yards and Docks, is inviting sealed proposals until April 23 for furnishing the New York Navy Yard with one turbo-generator with exciter set, five induction motors, one motor generator, two switchboards and accessories, together with installation of the same. The appropriation for the work is $44,000. Specifications will be furnished by the Bureau or by the commandant of the New York Navy Yard.

The Bureau of Supplies and Accounts of the Navy Department is inviting sealed proposals until April 12 for furnishing the navy yards at Norfolk, Va., and Pensacola, Fla., with a quantity of arc lamps, electrical supplies, conduit and fittings, rubber-covered wire and weatherproof cable. Blank proposals will be furnished upon application to the Bureau at Washington or to the Navy pay offices in the above-mentioned cities.

The Bureau is also inviting sealed proposals until April 26 for furnishing the navy yards at Portsmouth, N. H., Boston, Mass., and New York with one 24-inch electrically-driven engine lathe, one electrically-driven deck winch, and seven 20-hp. electric motors. Blank proposals will be furnished upon application to the Navy pay offices in the above-mentioned cities or to the Bureau at Washington.

Sealed proposals are being invited until April 9 for electrical work at Fort D. A. Russell, Wyo., as follows: For wiring buildings, furnishing and installing fixtures, wattmeters, etc., for constructing primary, secondary and arc light lines, furnishing and installing transformers, cut-outs, street light hangers, street lights, etc. All proposals previously received for the above work have been rejected. Full information, plans, specifications, etc., will be furnished upon application to Capt. W. S. Scott, Quartermaster U.S.A., Cheyenne, Wyo.

Hyatt Roller Bearings.

Ground has been broken and contracts let for a 75-foot addition to the new machine shop of the Hyatt Roller Bearing Company of Harrison, N. J. Although it is only six months since its large shops were completed the constant increased demand for Hyatt Bearings has made it necessary to again increase the plant. The new addition will be of brick construction, two stories high. The ground floor will be fitted with modern heavy machine tools, while the second floor will be used exclusively for assembling automobile bearings. The building will be completed by May 15.

PERSONAL MENTION.

Mr. Giuseppe Marconi, the father of the inventor, died at Bologna, Italy, Saturday, aged 83 years. William and another son were present at their father's deathbed.

Mr. Winthrop Murray Crane, ex-Governor of Massachusetts, has been elected to the directorate of the Western Telephone & Telegraph Company.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 22, 1904.

Electric Railways and Appliances.

755,140. Electric Railway-Signal. Bertram M. Kershner, Pittsburg, Pa. Filed June 21, 1902.

755,391. Electric-Railway Shoe. Henry Rosenfeld, New York City. Filed Aug. 19, 1903.

755,460. Electric Locomotive. William Dalton and Francis J. Cole, Schenectady, N.Y., assignors to the American Locomotive Company, New York City. Filed Nov. 17, 1903.

755,509. Car-Fender. George Linhard and Philip Linhard, Sublett, Mo. Filed March 9, 1903.

Electric Lights and Appliances.

755,306. Electric Tube-Lighting. Daniel M. Moore, Newark, N. J. Filed Jan. 19, 1903.

755,307. Electric Tube-Lamp. Daniel M. Moore, Newark, N. J. Filed Feb. 6, 1903.

Electrical Machinery and Apparatus.

754,980. System of Speed Regulation for Motor-Driven Machinery. Gano S. Dunn, East Orange, N. J., assignor to the Crocker-Wheeler Company, Ampere, N. J. Filed Aug. 20, 1903.

755,029. Armature Winding or Coil. Frank A. Merrick, Johnstown, Pa., assignor, by mesne assignments, to the Westinghouse Electric & Manufacturing Company. Filed Nov. 9, 1899. Renewed Dec. 16, 1901.

755,048. Automatic Circuit-Closer. James L. Russell, Boston, Mass. Filed Nov. 2, 1903.

755,066-755,067. Power-Transmitting Device. William R. Smith, Buffalo, N. Y. Filed July 18, 1903, and Aug. 10, 1903

755,141. Electrical Switch Mechanism. Hubert Krantz, Brooklyn, N. Y. Filed June 29, 1903,

755,165. Electric Switch. Ashley P. Peck, Milwaukee, Wis., assignor to the Hart & Hegeman Manufacturing Company, Hartford, Conn. Filed Sept. 21, 1903.

755,203. Electromagnetic Rail-Brake. Karl A. Wilde, Hamburg, Germany. Filed Dec. 1, 1903.

755,281. Electric Time-Switch. Joseph Dilhan and Ernest de Mersanne, San Francisco, Cal. Filed Aug. 27, 1903.

755,297 Automatic Circuit-Breaker for Electric Time or Other Switches. Arthur W. Hutchins, Providence, R. I. Filed May 15, 1903.

755,358. Retarding Device for Electric-Circuit Breakers. Algernon R. Cheyney, Philadelphia, Pa. Filed Dec. 2, 1903.

755,367. Static Electric Machine. Ernest E. Fewkes, Newton, Mass., assignor of one-half to Frederick W. Cole, same place. Filed June 1, 1903.

755,393. Electric Connection. Frank J Russell, New York City. Filed Nov. 6, 1903.

755,468. Rheostat. Arthur C. Eastwood, Cleveland, O. Filed Dec. 21, 1903.

755,537. Coil for Dynamo-Electric Machines. Ferdinand Porsche and Ludwig Lohner, Vienna, Austria-Hungary. Filed July 11, 1902.

755,590. Power-Transmitting Machinery. Edwin Winans, New York City. Filed Jan. 8, 1904.

Telephones and Telephone Apparatus.

754,968. Telephone. Martin C. Burt, Chicago, Ill. Filed March 17, 1903.

754,054. Service-Meter for Telephone-Lines. Charles E. Scribner, Chicago, and Frank R. McBerty, Evanston, Ill., assignors to the Western Electric Company, Chicago, Ill. Filed April 2, 1900.

755,091. Telephone-Transmitter. Joseph A. Williams, Cleveland, O., assignor to the Williams Telephone & Supply Company, same place. Filed April 10, 1903.

755,127. Electric Selective System. Julien A. Gehruing, St. Louis, Mo. Filed Feb. 8, 1902.

755,308. Service-Meter for Telephone Lines. Frank R. McBerty, Evanston, Ill., assignor to the Western Electric Company, Chicago, Ill. Filed July 16, 1900.

755,515. Counting System for Telephones. Johann H. Meyer, Madgeburg, Germany. Filed May 26, 1902.

Miscellaneous.

754,969. Storage Battery. Martin C. Burt, Chicago, Ill. Filed Aug. 13, 1903.

755,032. Apparatus for Wireless Transmission of Energy. Daniel M. Moore, Newark, N. J. Filed April 18, 1903.

755,121. Electrical Apparatus for Therapeutic Purposes. Frederick C. Fisher, Bristol, Eng. Filed Sept. 21, 1903.

755,142. Storage-Battery Construction. Simon Lake, Bridgeport, Conn. Filed Dec. 17, 1903.

755,173. Electropneumatic System of Driving, Johann Sahulka, Vienna, Austria-Hungary. Filed April 18, 1903.

755,229. Coil for Electromagnets or Other Purposes. Friedrich Klingelfuss, Basle, Switzerland. Filed Sept. 28, 1900.

755,282. Electromagnetic Separator. Myron Dings, Milwaukee, Wis. Filed May 23, 1903.

755,305. Peaked-Wave Wireless Transmission. Daniel M. Moore, Newark, N. J. Filed June 14, 1902.

755,382. Device for Testing Electric Currents. Charles Oliver, Woolwich, Eng. Filed Nov. 29, 1902.

755,487. Thermostat. Daniel H. Haywood, New York City, assignor to the Davis & Roesch Temperature Controlling Company, same place. Filed Dec. 23, 1902.

755,525. Stamp-Battery Guide. William S. McDonough, Ouray, Col., assignor of one-half to Thomas H. Woods, Ouray County, Col. Filed March 24, 1903.

755,546. Diffusion-Battery. Alois Rak, Cesky Brod, Austria-Hungary. Filed Aug. 1, 1903.

755,577. Electric Vibrator. William MacMillan, New York City, assignor of one-half to Egbert Winkler, same place. Filed July 29, 1902.

755,586. Method of Selecting Electrical Impulses. Daniel W. Troy, New York City. Filed July 11, 1903.

THE TELEPHONE WORLD.

Independent Companies Will Combine in Eastern New York.

With a view to making long-distance connection with Syracuse, Utica, Rochester, Binghamton, Buffalo and other towns of this State, Pennsylvania and Ohio, action has been taken at Troy for the consolidation of the Rensselaer Telephone Company of Troy, the Saratoga Telephone & Telegraph Company of Saratoga Springs, and the New Union Telephone Company of Glens Falls. The new company is to be known as the Commercial Union Telephone Company. The officers are: President, John T. Christie, of Troy; secretary, W. N. Burk, of Glens Falls; treasurer, Peter McCarthy, of Troy. The necessary action on the part of the old companies, it was announced, will be taken immediately.

It was said that before the end of the coming summer the long-distance connection would be made with Syracuse. The companies now have about 3,500 telephones in use.

It is the intention at once to extend the lines north to Plattsburg, east to North Adams and other Massachusetts cities, and west at an early date and form alliances so that in a few months direct connections can be made as far west as St. Louis.

For some time there has been talk of a local telephone exchange in Red Wing, Minn., in which D. M. Neill and associates purpose to interest themselves. The intent is to make it a distinctly Red Wing concern, in which all who desire may have an opportunity to to take stock. The company would connect with Independent lines throughout this and adjoining States, and particularly with the long-distance lines of the Tri-State Telephone Company, and also the Twin City Telephone Company. President E. H. Moulton, of these companies, has been in Red Wing for a conference on the subject.

The Farmers' Telephone Company, composed of agriculturists of Burlington and Camden Counties, N. J., are constructing a rural telephone service between Merchantville, Ellisburg, Maple Shade and Moorestown. The new line when completed will connect with the Delaware & Atlantic Telephone Company at Moorestown.

The Black River Telephone Company has completed the rebuilding of its long-distance system, and now gives excellent service to all points between Utica and Watertown, N. Y. Its system has been connected with the Utica Home Telephone Company system ever since the concern began business, but its service has been greatly improved lately.

The Saltfork Telephone Company has been organized for the purpose of constructing and operating a line from Quaker City, O., out into the country for several miles. W. N. Cowden is president, and H. H. Floyd secretary and treasurer.

The Belgian Government has completed a telephone line through a thick jungle, 750 miles wide, in the heart of Africa, which enables the various Belgian colonies to communicate with one another.

The Montpelier, O., Telephone Company has increased its capital stock from $15,000 to $50,000.

Stromberg-Carlson Company's Plant to be Enlarged.

It is announced that the Stromberg-Carlson Telephone Manufacturing Company, which has extensive buildings in Rochester, N. Y., is at once to make a considerable addition to its plant at that point.

Thomas W. Finucane said that the company will at once construct an addition to its cable department building. The addition will be 60 by 200 feet in size. This, said Mr. Finucane, would double the capacity of the cable manufacturing department.

The company owns ten acres of land on Culver road, adjoining the New York Central Railway. At the present rate of building, the entire tract will soon be utilized for buildings for manufacturing purposes.

Telephone Company's Expansion.

The Newark, N. Y., Telephone Exchange, which was established by William H. Kelley, in 1899, has now 230 'phones. Its capital is $25,000, which consists of $5,000 worth of 6 per cent. preferred stock, which has been subscribed by local business men, while Mr. Kelley will retain $15,000 worth of common stock, it not being expected that the balance will be issued. The exchange will be improved during the summer with a modern switchboard, and three miles of aerial, lead-covered cable will be installed. The Home 'phones in Wayne County now connect with Lyons, Clyde, Savannah, Butler, Wolcott, Rose, Sodus, Williamson, Ontario, Walworth, Macedon, Palmyra and Newark. Exchanges will be installed at Palmyra and Marion during the coming summer.

These exchanges are connected with Phelps, Clifton Springs, and over the Interocean line with Geneva, Canandaigua, Rochester and Buffalo and many other towns throughout the State reached by the Independents.

At the annual meeting of the Gage County Independent Telephone Company, held at Blue Springs, Neb., the following officers were elected: A. R. Morris, president: A. S. Reiff, vice-president; J. B. Graham, secretary; Dr. W. L. Albin, treasurer.

The Armstrong Telephone Exchange Company of Truman, Minn., has filed an amendment to its articles increasing its capital stock from $25,000 to $100,000, and its limit of indebtedness from $5,000 to $25,000.

The Cumberland Telephone Company has opened an exchange for business in Rayne, La., with about 100 subscribers. This same company is to establish an exchange at Belzona, Miss.

The municipal boards of Meridian, Miss., have granted a franchise to a new telephone company which promises good competitive service.

The Hay Springs-Alcove, Neb., Telephone Company, with a capital stock of $25,000, has filed articles of incorporation with the Secretary of State.

The Dutchess County Telephone Company of Poughkeepsie, N. Y., reports a constantly increasing demand for its service.

Independent Lines to Co-operate in Service.

The Association of Long-Distance Telephone Companies, the object of which is to provide for telephonic communication over Independent lines between Philadelphia and Kansas City, was formed at a meeting of telephone magnates, including several Louisville, Ky., men, which was recently concluded at Indianapolis, Ind. The range north and south will be from Michigan to Kentucky, inclusive.

J. D. Powers, of the United States Trust Company, one of the Louisville delegation, said of the plans:

"There were 40,000 miles of Independent long-distance lines represented at the meeting. All arrangements were made to fill in the gaps between Philadelphia and Kansas City at an early date, and before many months have passed we will be in the field for long-distance telephone business on a better basis than was ever before offered the public.

"The organization of this new association should in no sense be taken to mean that there was an amalgamation of the interests involved. It only means that the Independent long distance telephone lines will co-operate in giving long-distance service."

The system will be put into use as soon as practicable. Before a thorough system is possible, however, it will be necessary to make connections between several small gaps in the proposed territory.

The stockholders of the Adamsville, O., Telephone Company held a meeting and elected the following officers: President, J. B. Rhodes; vice-president, C. H. Hanks; secretary, F. P. Winn; treasurer, M. F. Tomlinson; manager, F. P. Winn; counsel, S. M. Winn. The stockholders made plans for the construction of an up-to-date exchange. The farmer lines will also be extended into the rural districts adjacent.

The report of the American Telephone & Telegraph Company for 1903, issued last week, showed gross revenue of $16,545,632, an increase of $3,268,175; net revenues, $10,564,665, an increase of $2,729,393; dividends, $8,619,150, an increase of $2,035,000, and balance, $1,945,514, an increase of $694,000. In the course of the year $35,368,700 was spent for exchanges, toll lines and land and buildings, and 677,228 miles of wire were added to the plant.

The cables of the new Prospect telephone exchange at Clinton and Atlantic avenues, Brooklyn, N. Y., were recently cut in. The building is seven storied, fireproof and cost $350,000. The switchboard is unusually large, and can accommodate 12,000 subscribers.

Telephone Incorporations.

The Farmers' New Era Telephone Company, Hebron, Ill. Capital stock, $5,000. Incorporators: George Hunt, L. A. Nichols and J. H. Turner.

The Sangamon Telephone Company, Williamsville, Ill. Capital stock, $2,500. Incorporators: J. M. Cooper, P. J. Telfer and R. U. Richardson.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Ashland, O.—C. W. Garver, clerk of the board of trustees, wants specifications at once for an electric light plant.

Bridgeport, Ala.—B. C. Jones, city clerk, states that a franchise has been given to A. Grant Davis, of Parkersburg, W. Va., for the erection of an electric light and power plant.

Cadiz, Ky.—From present indications it looks as though this city is to soon have an electric light plant. E. E. Wash, of this place, and Joe. L. Parsley, of Princeton, have been figuring on putting in a plant of this kind, and are greatly encouraged by the city council.

Coalville, Utah.—A petition has been presented to the city council signed by C. A. Callis, T. L. Beech and others, asking for a 50-year franchise to install in the city an electric light plant. The matter was referred to the committee on city property.

Cody, Wyo.—Hon. George T. Beck, has been granted an exclusive franchise to supply electric light to this place. Col. Cody is associated with Mr. Beck in the enterprise, and a plant will be installed within the next two months.

Excelsior, Minn.—This city is to have a new electric lighting system soon.

Flora, Ind.—This town is considering the advisability of having an electric lighting plant.

Fulton, Ky.—Lewis Graham and his assistants have purchased a controlling interest in the electric light and power plant.

Gurdon, Ark.—The city council has granted to S. S. Harris and Dr. T. L. Hodges a franchise for an electric light and power plant. Work will begin at once to secure estimates on the plant.

Hackensack, Minn.—There is considerable talk of putting in an electric light plant here.

Jackson, Mich.—Frank Cornwell, of Ann Arbor, president of the Ypsilanti Paper Company and the old Jackson Pulp Company of this city, is seeking a franchise to build an electric light plant on the Huron River at Foster's Corners.

Jacksonville, Fla.—The proposition to bond the city for waterworks and to enlarge the electric light plant is said to be favorably considered by many citizens.

Knox, Ia.—The Knox electric light plant has been sold to Thomas A. Grist, who will improve same and add new machinery.

Lodi, O.—This village has entered into a contract with Clement Williams, of Akron, to light the town with electric lights.

Newport, Ky.—The amount of $10,000 has been set aside for the municipal electric light plant, and $50,000 will be added yearly until the required sum is obtained. J. B. Morlidge, city engineer.

Ottawa, Ont.—It has been determined not only to light the whole stretch of the Welland Canal by electricity instead of gas, but by the same motive power to operate the gates, valves, bridges, and sluceways of the canal. The electricity will be furnished by the Cataract Power Company.

Perryville, Mo.—L. M. Moore, formerly of this city, is trying to interest local capitalists in the establishing of an electric light plant here.

Rockville, Md.—A bill is before the Legislature to authorize the expenditure of $50,000 for water, sewer and an electric light system. Eugene Jones, Cornelius W. Clum, Theodore J. King, William L. Lewis and J. B. Stubbs are on the committee to consider the matter.

Rusk, Tex.—An electric light plant will be erected by W. W. Welsch, Dr. Wiggins and others.

San Antonio, Tex.—Bids are asked until April 6 for lighting the streets with gas or electric lights for two years, with the privilege of five years. John P. Campbell, mayor.

San Bernardino, Cal.—The San Bernardino Gas & Electric Company will install new machinery in the proposed sub-station.

San Diego, Cal.—The council has granted Charles E. Sumner, of Cleveland, O., an electric light and gas franchise here.

San Jose, Ill.—The matter of erecting an electric light plant is now being agitated. T. O'Neil is interested.

Springfield, O.—It is reported that the electric lighting company will install a new system for the streets.

South Stillwater, Minn.—The village council has decided to advertise for bids for $15,000 in bonds to be used in erecting an electric light plant. Bids will be opened April 2.

Statesboro, Ga.—Sealed proposals will be received until April 12 by the mayor for the erection of an electric light and waterworks plant. The electric light plant will consist of one 90 kw. alternator, one 135 hp. automatic engine, 20 arc lamps, wire transformers, pole lines, etc.

Table Grove, Ill.—This village is figuring on purchasing an electric light plant.

Taunton, Mass.—The Legislature approves of the appropriation of $2,343 to install an electric light plant for lighting and heating the Taunton Insane Hospital.

Tipton, Ind.—Dynamos with a capacity of 10,000 incandescent lights will be installed by the city electric light plant.

Uniontown, Ky.—The electric light plant has been sold to C. F. Cecil, of Springfield, Ky. Improvements will be made.

Weeping Water, Neb.—John Cook, of Julian, is applying to the council of this city for a franchise to put in an electric light plant.

Williamsburg, O.—Appropriation has been made, but bonds for erecting the electric light plant have not been sold. One contract will be awarded to cover all work. Plans and specifications have been prepared. C. H. Lockard, mayor.

Wise, Va.—A company has been organized by Gen. R. G. Ayers, of Big Stone Gap, Judge Fulton and others, to supply electric lighting and water here.

Youngstown, O.—A co-operative electric lighting and power plant is one of the possibilities in the near future for this city. B. M. Moss, manager of the Scotch Woolen Mills Company, is at the head of the project.

STREET RAILWAYS.

Albany, N. Y.—A four track electrically equipped railroad, for 35 miles between New York City and Croton—two tracks for fast trains and two for trains running practically without schedule, after the manner of long-distance trolley lines—is the plan behind a bill introduced last week by Assemblyman Apgar at the behest of the New York Central Railroad Company.

Atlanta, Ga.—The Piedmont Electric Railway Company has been incorporated by E. C. Atkins, T. J. Hightower and others, to build a line from this city to Roswell, Alpharetta and Cumming, Ga., a distance of 23 miles.

Bessemer, Ala.—At a late meeting of the city council, franchises were granted to the Bessemer Blue Creek and Blocton Electric Light & Power Company, which proposes to build a line of steam or electric railway, connecting Bessemer with 60,000 people who inhabit the mining regions contiguous to this city.

Elmira, N. Y.—The Elmira & Corning Short Line was lately incorporated with a capital of $500,000, to operate an electric railroad line from here to Corning, a distance of 13 miles.

Ithaca, N. Y.—If the plans of the promoters go through, and there is now every indication that they will, Binghamton and this city will be connected by an electric line.

Newark, Ark.—The Syracuse & Eastern Electric Railway Company has been granted a franchise here.

Rockford, Wash.—There is some talk about an electric railroad through this place to connect with the beet sugar factory at Waverly. Farmers have expressed a willingness to donate a right of way through their farms for the enterprise.

Scranton, Pa.—The Delaware, Lackawanna & Western Railroad in installing an electric traction system in anthracite coal mines near here, to take the place of mules, expended $129,000 last year.

Sioux City, Ia.—The Sioux City Traction Company will make improvements this season costing $50,000.

Whitestone, N. Y.—The Belmont Syndicate is asking for a franchise to build a trolley line here.

POWER PLANTS.

Asheville, N. C.—B. F. Burk and G. A. Shideler, of Marion, Ind., are contemplating establishing an electric power plant here during the coming summer.

Eureka, Cal.—The Eureka Lighting Company, of which T. D. Petch is superintendent, will develop water power on Trinity River for generating electricity for power and light. It is said that $500,000 will be expended upon the plant and general improvements.

Oneida, N. Y.—De Witt C. Hadcock, of this city, recently took C. C. Morgan, general manager of the Stanley Electric Manufacturing Company of Pittsfield, Mass.; H. H. Barnes, chief engineer of the same company, and W. H. Hand, a representative of Cramps' shipyards of Philadelphia, to inspect the Limekiln Falls on the Oneida Creek. It is proposed to harness the falls and generate electricity for motive power. It is expected that enough can be generated to furnish power for Oneida and all of Madison County.

Sundance, Wyo.—The Economic Power Company, organized by Henry K. Mayham, of Denver, will build a $900,000 power plant west of this place, and supply power and electric light to many towns and mines in the Black Hills.

NCTES FOR INVESTCRS.

Latest quotations for copper are: Electrolytic, 12⅝@13c.; Lake 12⅞@13c.; casting, 12⅝@12¾c.

The stockholders of the Fresno Traction Company of California will vote May 18 on issuing $5,000,000 for extensions.

The annual stockholders' meeting of the Marconi Wireless Telegraph Company will be held April 18 at noon in Jersey City.

The governing committee of the New York Stock Exchange voted to close the exchange on Good Friday but not on the following Saturday.

The directors of the Electric Storage Battery Company have declared the regular quarterly dividends of 1¼ per cent. on both the common and preferred stocks.

The Bell Telephone Company of Missouri will vote on an increase of its capital from $4,000,000 to $10,000,000 at a special stockholders' meeting, to be held May 17.

As soon as market conditions will permit, the Keystone Telepone Company of Philadelphia will ask authorization to issue $5,000,000 bonds, of which $3,500,000 will be sold at once.

It is reported that the gross business of the National Carbon Company for the first quarter of the current year will show an increase of 10 per cent. as compared with the same period of 1903.

Electric lamp manufacturers of the United States have been in conference in Cleveland, O., for several days. It has been agreed that the several manufacturers maintain but one price for the same grade of goods.

The Boston Suburban Electric Company has declared a quarterly dividend of 50 cents per share, payable April 15 to stockholders of record March 30—a reduction of 50 cents from the previous dividend.

The tax valuation of the New York Edison Company has been raised from $9,650,000 in 1903 to $11,515,000 this year, and that of the New York Telephone Company from $2,831,000 to $4,592,000.

It is stated officially that the General Electric Company will show an increase in its earnings for February and March of nearly 10 per cent. each month as against the corresponding months of last year.

A deed conveying all of the property of the Michigan Telephone Company to the Michigan State Telephone Company, as the assignee of N. W. Harris, the purchaser under foreclosure, has been filed in Detroit.

The stockholders of the Birmingham (Ala.) Railway, Light & Power Company at a special meeting voted to authorize the directors of the company to issue $10,000,000 worth of refunding bonds, the same to bear interest at the rate of 4½ per cent.

The Brooklyn Rapid Transit Company has spent during the last year over $1,300,000 in purchasing minority stock of subsidiary companies. The money to make these purchases was obtained from the last sale of 4 per cent. bonds. The outstanding stock of the subsidiary companies now amounts to only $995,000.

Attorney-General Guion of Louisiana has brought suit against the New Orleans Railways Company, a New Jersey corporation, to have the company declared unconstitutionally incorporated and therefore unable to do business in Louisiana. The company has a capital of $80,000,000 and most of its bonds are held in New York. It controls all the street and suburban lines of New Orleans, besides owning the gas works and electric light plants of that city.

ELECTRICITY.

VOL. XXVI. NEW YORK, APRIL 6, 1904. NO. 14.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.......................... 3.00
Single Copies.........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

Electrical Pumps for Fire Protection.

A little over a month ago we referred in these columns to the talk that was going on by the mayor and some of the city fathers of utilizing salt water below 42d street in Manhattan Borough for fire purposes.

From present indications this was not *mere* talk, and it really looks as though the city will in the not very distant future have an independent system of salt water mains with the North and East Rivers as the storage reservoir.

This question of adequate water supply for fire purposes is being agitated through Fire Chief Croker, who complains of inadequate pressure in the existing system. In a recent interview he is reported as saying:

"The circulation pressure of water through the system of this city is so poor that the Fire Department has been handicapped at every large fire that it has been called on to fight during the last winter. Tests that have been made at the hydrants from time to time independent of the facts recorded at the fires show that the water pressure has been all winter and is now way below what it should be. I need only cite the facts recently acquired at big fires to prove this. Last Sunday (March 27) I had the water pressure taken at several hydrants on lower Broadway near the scene of Saturday's fire (March 26), and found that the pressure that day, when there was no drain on the water supply, as there is on a business day, was only ten pounds, when it should have been thirty pounds at the lowest."

The mayor has requested the borough engineers to prepare plans for a salt water system of supply. In designing the system it is sincerely to be hoped that the scheme suggested by ELECTRICITY on August 1, 1900, and again by the mayor recently, of having electrically operated pumping stations will be adopted. With a number of electrical pumps, operated by surplus current from the elevated and surface roads, there should be no complaint of lack of pressure. In the event of a fire the pumps could be started instantly by turning a switch and there would be no valuable time lost in shaking up or starting fires as would necessarily be the case with steam pumps. This feature of the proposed system should receive careful consideration by the designing engineers.

January Exports of Electrical Machinery.

A careful examination of the list of exports of electrical machinery from the United States to foreign countries for the month of January, which has just been made public, should prove interesting, especially to electrical manufacturers. All the machinery exported during that month reached a value of $445,099.

During January Great Britain was our best customer and purchased $93,686 worth of machinery. Strange as it may seem, of all the other civilized countries of the world Japan comes next with a total purchase of $71,518.

Spain either has no use for electrical apparatus or still harbors against us a feeling over the late war, for that whole country only spent during January $87 for American made machinery.

As Russia bought but $5,865 worth it is only fair to assume that Germany has a strong hold on its market for electrical machinery.

That this country is gaining a foothold in British South Africa may be inferred

by the item of $6,585 charged against that section.

To our own possessions, the Philippines, we sold $2,657 worth, the bulk of which probably was electric motors for trolley cars.

Numerous other countries purchased electrical goods from the United States during January in small amounts. A careful study of the statistics should prove interesting to manufacturers seeking to extend their export trade.

* * *

Report on the Paris Subway Disaster.

A report has just been prepared by a committee appointed by the Municipal Council of Paris, France, to inquire into the causes that led to the disaster in the underground tunnel of that city last August. According to the *Electrician*, London, the report is a very voluminous one. The principal recommendation, however, of the Technical Committee is that arrangements be made so that the trainmen may in case of necessity cut the current off the conductor rail at any point. It suggests that the rail be cut up into a number of separately fed sections, so that not more than five or six trains can be on any one section, and that every train shall carry a "short-circuiting bar" which can be dropped across the conductor and running rail in case of need and so actuate the circuit-breakers controlling the section. This is otherwise described as "a metallic arrangement with an insulated handle," and is apparently to be operated from the driver's cabin. The next most positive announcement is that the lighting of the stations and tunnels should be provided from a number of sources, some of them entirely independent, not only of the traction supply—as the lighting always has been—but even of the company's generating and sub-stations.

In view of the near completion of the New York rapid transit subway the findings and recommendations of the Paris committee should prove valuable, and the full report should be carefully read and studied by the Rapid Transit Commission.

* * *

Converting Steam Roads to Electricity.

The question of changing the motive power of steam railroads to electricity is receiving considerable attention in England at the present time. The subject was brought up before the London Institution of Electrical Engineers on March 10 in a paper by Mr. F. F. Bennett, who tried to demonstrate by means of detailed estimates, based on the total railway system of the United Kingdom, what railway companies stood to gain by proceeding "right off" with conversion to electric traction. He argued with the companies that they were quite wrong to proceed as at present by electrifying here a little and there a little. The paper came in for much criticism and it cannot be regarded as epoch-making in respect to electric railway literature, but it served as a text upon which to base a discussion. The majority of electrical engineers would rather see such sections as the Liverpool & Southport line (which is described elsewhere in this issue) opened than wait for amalgamation or uniformity of working to be brought about between railway companies. The Liverpool & Southport line is the most important piece of railway electrification that has yet been carried out in England, and the general belief is that it is *the* experiment (47 miles of track) which will lead to big things very soon. A few practical working results, such as we have referred to already in the case of the Mersey Railway and the benefits which are bound to accrue from the up-to-date equipment of the Liverpool & Southport section, will go a long way to convince—and move to action—the English railway manager and director. These are the men who are generally regarded as being obstacles in the way of electric traction.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The first section of the rapid transit subway in Manhattan, which was to have been opened to the public in June, will probably not be in operation until around October 1. This is partly due to delay in getting the dynamos and other electrical apparatus installed in the power house.

Representatives of the Japanese Government, including S. Tada, of the Japanese Navy, and Messrs. Timita and Nishikawa, electrical engineers, of Tokio, are in this country to purchase electrical machinery.

A British contemporary states that a railway to be operated by electricity will shortly be built between Rome and Naples in Italy. It will run from Rome across the Pontine Marshes to Terracina and thence to Formio, a small town which is practically a suburb of the important garrison town of Gaeta, and thence to Naples, following more or less the line of the coast. Energy will be derived entirely from water power, and mainly from the Tiber and the Volturno, the latter river almost bisecting the line and being capable of supplying the greater part.

Lead and zinc mining in the Galena-Joplin district of Missouri is to be revolutionized by using electricity instead of steam.

The Roentgen Rays Society will hold its convention in September in Cleveland, O.

The arrangements made by the Belgian Government for the sending of commercial messages by wireless telegraphy from Nieuport to the Dover-Ostend steamers have involved the establishment of a new Marconi station at Nieuport-Bains, says the London *Electrical Engineer*. The new station is equipped with the latest apparatus, and the staff of operators will maintain a continuous service.

An effort will be made before the Ohio Legislature adjourns to have that body pass a bill creating a Street Railway Commission, with powers to handle in some manner the question of traction franchises in the various cities of the State.

"Motorpathea cerebralis," the new disease to which chauffeurs are subject, is diagnosed by the London doctor who has discovered it as producing "temporary disorganization of the mental functions" and "derangement of the equilibrium of the nervous system."

A number of lightships and lighthouses along the east coast of England are to be fitted with wireless telegraphy apparatus with a view to the preservation of life at sea. If the experiment proves a success, according to an English contemporary, the balance will be similarly equipped.

The minerals collected during the work of excavation for the subway in this city are to be exhibited by the Rapid Transit Commission at the St. Louis Exposition.

German capitalists purpose to build 90 miles of electric railway from Cienfuegos, Cuba, with lighting plants for eight towns and a 10,000 hp. hydraulic plant. Contracts for construction will be let in about three months.

The Magnetic Club will hold its spring meeting at the Hotel Spalding, 127 West 43d street, this city, Thursday evening, April 21, at 6:30 o'clock. The officials of the telephone companies will be the guests of the evening.

THE LIVERPOOL-SOUTHPORT ELECTRIC RAILWAY.

(From our London Correspondent.)

The Lancashire & Yorkshire Railway has been converted so far as its Liverpool to Southport service is concerned from steam to electrical working, and while the main object in view is to regain the traffic which has been drawn away by the electric trolley competition, the general manager, Mr. J. A. F. Aspinall is one of the few English railway officials who has long realized that electricity permits of a greater development of traffic, even without any considerations respecting competition from tramways, than is possible under steam conditions.

The entire contract for the electrification of 47 miles of track, a power house with 12,000 hp. of plant and the complete train system, has been carried out in less than twelve months, and that without interfering with the running of the steam service. The contractors for everything save the rolling stock—which was built at the railway company's own shops—was carried out by the London firm Dick, Kerr & Co., Ltd.

Before proceeding to describe the system, I may mention that this is the first main line steam railway of any length in England to complete its electrification. The Mersey tunnel railways, to which reference has already been frequently made in these columns, is a short length of line of a special and exceptional character.

The distance between Liverpool and Southport is nearly 18½ miles, the total length of track equipped being equal to 47 miles of single line. There are few gradients and curves. There are fourteen intermediate stations, which lie at an average distance of about one mile apart on the southern most part of the route, but are more widely separated on the northern portion.

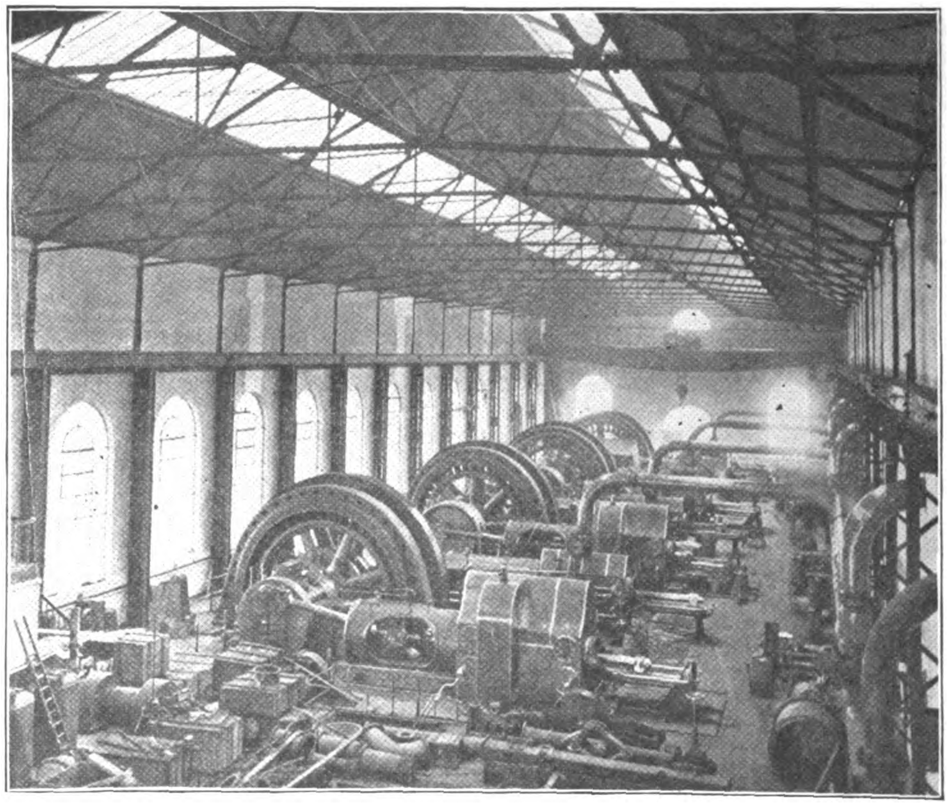
Under steam conditions there are about 36 trains per day in each direction between Liverpool and Southport; a similar number running in each direction between Liverpool and Hall Road, a station some seven miles from Liverpool. The majority of these trains stop at every station. A few express trains are run in between, these requiring 25 minutes, while the stopping trains take 54 minutes and the Hall Road stopping trains 25 minutes. The total train mileage per diem is about 1,900.

With electrified conditions the train mileage is being increased to 3,200. The number of trains between Liverpool and Southport, in each direction, will be increased from 36 to 65, and between Liverpool and Hall Road from 38 to 54. Furthermore, the running time from Liverpool to Southport will be decreased from 54 minutes to 37 minutes, and from Liverpool to Hall Road from 25 minutes to 17 minutes. Express trains will also be run.

Energy for working the line is generated as three-phase alternating current of 7,500 volts, this being transmitted direct to substations where the voltage is stepped down by static and transformed by rotary converters into direct current of 650 volts pressure, the maximum voltage at the train being 600.

The power house is situated at Formby, approximately the center of the line; it also serves as a substation for feeding to the adjacent track. In addition to the rotary converters at the main power house the scheme embraces three substations located respectively at Sand Hills, Seaforth and Birkdale. Near Liverpool it has been necessary to locate the substations closer together than on other parts of the line in order to cope with the considerably heavier traffic of some of the local trains. The extreme ends of the line—from Sand Hills substation towards Liverpool, and from Birkdale substation towards Southport and Crossens—are each fed by one substation, whilst for the intermediate sections of the line two substations participate in supplying energy to the trains, the demand of energy supplied from each substation depending on the position of the train between the substations. The substations are situated near the track, thus avoiding any low tension cabling, except a short connecting length. Any substation can be disconnected when required.

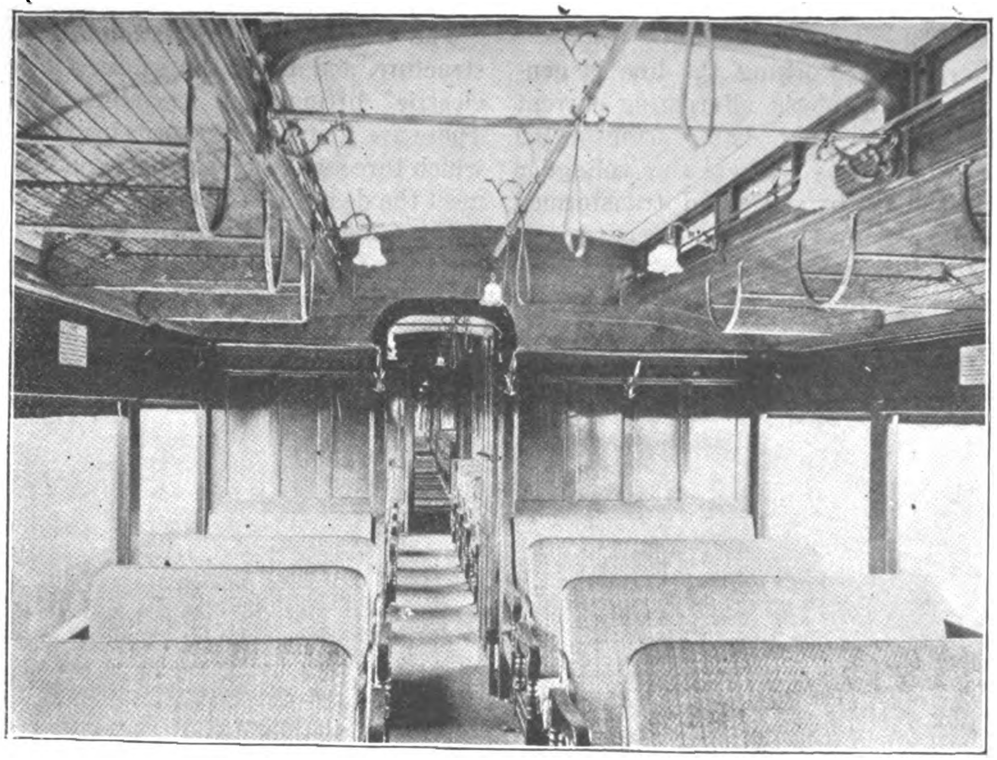
The Formby power station is a plain structure, and is of course served with electric lifting and traveling cranes. There are four 1,500 kw. sets installed, of which three will under normal conditions, meet the demands. There is also a fifth unit, of 750 kw., which will form a useful link between the larger units, and thus permit considerable flexibility in obtaining a good load factor with high efficiency.



View of Main Generating Station (Formby) on the Liverpool-Southport Electric Railway.

There are sixteen Lancashire boilers (Yates & Thom manufacture) each 32 feet x 8 feet 6 inches, constructed for 160 lbs. working pressure. A Galloway superheater is fitted in each of the downtake flues at the back end of the boilers. The boilers are arranged in two batteries of eight. Green's economizers, and induced draft apparatus (supplied by the Buffalo Forge Company) are employed. The steam feed ring (6 inches diameter) runs the whole length of the boilers, branches to each boiler being taken through check valves. The ring is supplied from the pumps in triplicate. The feed water can be passed either through the economizers or direct to the boilers by a duplicate system. The main steam piping is 12

inches in diameter and is a combination of the ring and by-pass systems. The steam pipes are in duplicate and are of steel. The exhaust pipes from the main engines are 24 inches in diameter and connected direct to jet condensers. The whole of the exhaust piping from exciter sets, fan engines, and boiler feed pumps is connected to an auxiliary surface condenser.

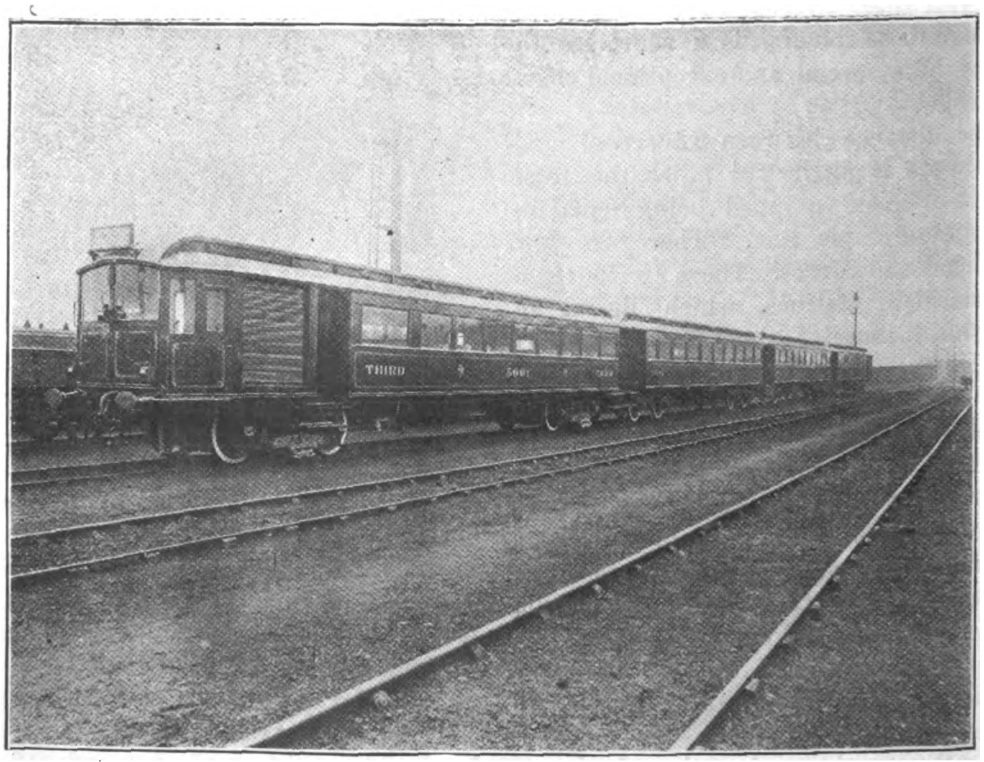


View of Interior of Car on the Liverpool-Southport Electric Railway.

The four main engines are also of Yates & Thom build, that firm having acted as sub-contractors to Dick, Kerr & Co. They are of the horizontal cross compound type (cylinders 32 inches x 64 inches diameter x 4 feet 6 inches stroke) and run at 75 revolutions per minute. The normal load of each engine is 2,310 hp. (160 lbs. pressure) but they are designed to give an overload of 20 per cent. Each flywheel is 22 feet in diameter, and is directly attached by strong bolts to the rotor, which is otherwise independent of the flywheel. Each engine has a motor-driven bearing gear.

The alternators are three-phase, 25 cycles, and they were built at the Preston factories of Dick, Kerr & Co., together with all the other electrical equipment. Each rotor or magnet wheel is carried between the cranks, the armature ring or stator being erected on its own slide beds, concreted in and bolted down on the engine foundations. The rotor carries 40 radial cast steel poles of oval section secured by tap bolts to the outside rim of two finished cast steel rings of massive T section carried and driven from a central cast iron spider by 16 axial bolts.

The pole tips are of laminated steel with a central air space—corresponding to grooves on the pole sides and the clearance between the rotor rings—dovetailed tight into the poles to keep the field coils in position. These are of bare copper strip wound edgewise. The outer surface of the coils is left bare to aid the dissipation of heat, while the central ducts on the poles give ample ventilation to the iron.



Four-Coach Train on the Liverpool-Southport Electric Railway.

The cast-iron spider is built in halves and clamped on the shaft by four heavy bolts. The magnet rings are also in halves but staggered relative to each other and the spider and shrunk together by double headed keys.

The cast-iron slip rings are of stiff section carried on either side of a cast-iron spider by axial bolts insulated with ebonite. On each slip ring bear three carbon brushes.

The weight of the magnet wheel complete is about 48,500 lbs., of which the poles account for 12,800 lbs. and the spools 6,350 lbs.

The stator consists of a cast-iron frame carrying the core disks on its inner periphery. The core segments are of annealed iron, punched in sections with their paper insulations. The sections break joint to equalize the reluctance and are strung true on through bolts that clamp them up between a deep internal flange and a stiff cast-iron end ring built in sections. The complete stator weighs 75,800 lbs.

Each coil is fully insulated, dried and tested to 15,000 volts before being inserted in the slots, the stator when completed being adequately tested. Special ventilation ducts are provided, the rotating field forcing cool air through these ducts and out at apertures cored in the frame. The winding of each phase is distributed over two slots per pole. The connection is star, with center earthed. The stator terminals consist of three high tension porcelain pots carried on a bracket at the bottom of the frame and inclosing the bare couplings. In each alternator provision is made for shifting the stator axially by ratchet jacks to clear

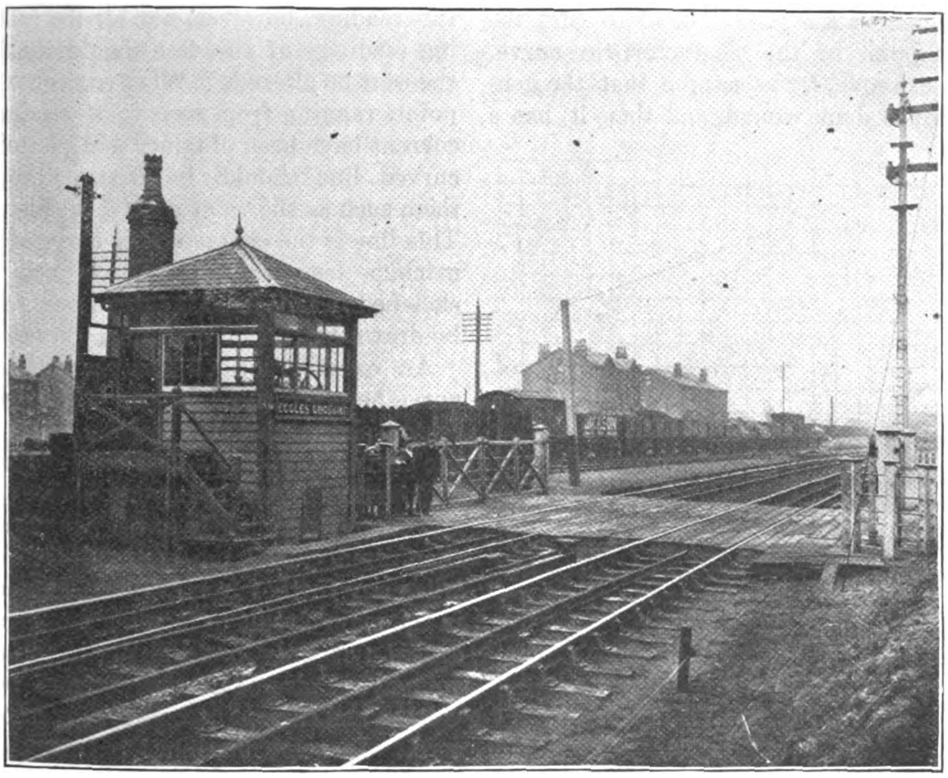
the rotor and give comfortable access to the windings.

There is also a fifth engine, a vertical cross compound (23 x 46 inch cylinders x 3 feet 6 inch stroke, developing 1,180 hp. at 94 revolutions per minute) driving a 750 kw. alternator of almost identical construction to the larger sets.

There are three Dick, Kerr–Willans & Robinson direct current exciters, four poles, 100 kw., running at 380 revolutions, the working voltage being 125. These machines also light the station and work the ash conveyor and bearing motors.

bracket with rotary converter bus-bar voltmeter and paralleling voltmeter; all the substation gear being for the local substation at Formby.

The whole of the high tension switch gear, oil switches, instrument transformers and bus-bars are erected in a fireproof H. T. chamber, the dimensions of which are 79 feet x 12 feet, and constructed of steel girders and concrete. Connection between the terminals of each stator and its oil switch is made by short leads to a trifurcating box in the pit, thence by a three core H. T. lead covered



Eccles Crossing, with Break in Conductor Rails, on the Liverpool-Southport Railway.

The main switchboard is erected on a gallery over a fireproof high tension chamber, and is built up of thirty-three 2 foot panels of enameled slate. Starting from the right there are swing brackets carrying two alternating current bus-bar voltmeters reading to 8,000 volts, synchronizing voltmeter 0 to 16,000 volts and synchronograph with lamps. Five main alternator panels, one blank panel, one total station power panel, six high tension feeder panels for distant substations, three exciter panels, one substation total power received panel, four high tension substation transformer panels, one blank panel, four rotary converter direct current panels, one blank panel, one substation total power delivered panel, also comprising one sub-panel switch for starting rotary converter from direct current 600 volt bus-bars; four substation feeder panels; lastly, one station lighting and blower-motors' starting panel, and swing

cable passing along an independent duct through the foundation up to the cellar ceiling, along which it is run by ducts through the H. T. chamber floor, where it ends in a second trifurcating box on the wall. The rest of the H. T. wiring is by individual conductors. The three-core H. T. leads are of stranded copper cable, paper insulated and lead covered. The single cables are rubber insulated taped and braided; they were designed to pass a flash test of 25,000 volts between the phases and each to earth. The solid copper rod H. T. bus-bars are insulated in a similar manner, and reduced in section from alternators to local sub-station panels as power is tapped. The bus-bars and individual leads are carried on corrugated H. T. porcelain pots, connection between oil switch and bus-bar being made through a H. T. insulating or "hook switch." In the instrument transformers supplied with the ammeters by Messrs. Elliott Brothers the primary is simply a straight length of lead or bus-bar inclosed by the secondary and iron circuit. In the wattmeter current transformer supplied by the Stanley Wattmeter Company, with its meters, the primary consists of a few turns in series with a bus-bar. The voltmeter transformers were built by Messrs. Dick, Kerr & Co., Ltd., the voltmeters by Messrs. Elliott Brothers, who also supplied the panels for the main board, the switches and circuit breakers being made at the Preston Works.

In all cases the low tension secondary leads pass through the ceiling to the switchboard above.

The total alternating current power generated, before passing to the sub-station feeders is recorded in an integrating wattmeter. Connection to each triplet of transformers in the substation is made through a hook switch, oil switch and three cast-iron tail-end glands, bushed with corrugated porcelain bobbins, piercing the front wall of the chamber. Each transformer is single-phase split-phase and has two independent secondaries, the six of the triplet being grouped in double mesh to afford six phases for operating the rotary converters. Connection between the grouped secondaries and the six rotary slip rings is made through a pair of three-blade switches carried on a stand, on which is also placed the equalizer switch for the series field.

The chief feature of the alternating board is that the high tension current is confined to the pit below the board, this being effected by the long arm oil switches which are used throughout the system.

The rotor field rheostats are of massive construction, and consist of cast-iron grids insulated with hard micanite and assembled in frames forming layers in a vertical stack which open top and bottom for thorough ventilation.

(To be continued.)

ELECTRICAL STATION PRACTICE.

ARTICLE XXXI.

BY W. H. RADCLIFFE.

In the operation of electrical stations, many problems dealing with the generators installed can be readily solved by the aid of characteristic curves, which curves bear practically the same relation to the generators as do indicator diagrams to steam engines. In steam engineering, a man who did not fully understand the method of taking an indicator diagram would be considered as not in touch with this profession, and in electrical engineering the same would be true of one ignor-

ant of the method of obtaining characteristic curves.

The necessary arrangement or connection of the generator from which it is desired to obtain a characteristic curve consists in providing a constant motive power so that the machine may be run at a uniform speed, and when the field magnets of the generator are separately excited the field current from the outside source must also be maintained constant, preferably by a rheostat connected in the field of the auxiliary machine. It is also necessary in every case that means be provided for varying the main current step by step from zero to maximum. This may best be done by employing a water rheostat. A convenient form of water rheostat consists of an iron tank containing a super-saturated solution of salt and water into which an iron plate may be raised or lowered at will. One of the main conductors from the generator is connected to the iron tank, and the other main conductor is joined to an ammeter, circuit breaker, and the iron plate connected in series. The iron tank should rest upon wooden planks placed upon the floor, and the movable iron plate should be supported by a heavy rope which must be led over two elevated pulleys one of which should be mounted directly above the center of the tank and the other at the same height but several feet distant from it. The free end of the rope should be weighted so that the iron plate may readily be moved up and down in the salt solution contained within the tank. In order that the characteristic curves obtained from shunt wound machines be of the most practical value, the curves should commence at the point of rated voltage for no load, thereby necessitating for each case a rheostat in series with the shunt field winding.

The measuring instruments that will ordinarily be required, in conducting the test for a characteristic curve, are a voltmeter connected across the armature terminals, an ammeter joined in series with the main circuit, and a portable tachometer applied directly to the end of the armature shaft for measuring its speed in revolutions per minute. During the test, one man should be assigned to the tachometer, another man to the water rheostat, and there should preferably be one man at each of the electrical measuring instruments In order to enable the man at the tachometer to keep the speed constant, he should be in communication either directly or indirectly with the source of the driving power, and the man at the water rheostat should be in plain view of the man reading the ammeter so that the latter party may signal him for the proper adjustment of the rheostat in order that the desired increase of current be obtained for each set of readings.

Having completed the preliminaries just mentioned, the test should be started with the main circuit of the generator open, that is, with the iron plate of the water rheostat raised above the solution in the tank. Then, in the case of the shunt machine, the speed should be made normal and the field rheostat adjusted until the voltmeter reading indicates the rated voltage of the machine at no load; sufficient data is then at hand to plot the first point of the characteristic curve. For example, let us assume that the generator is shunt wound, and that it has a

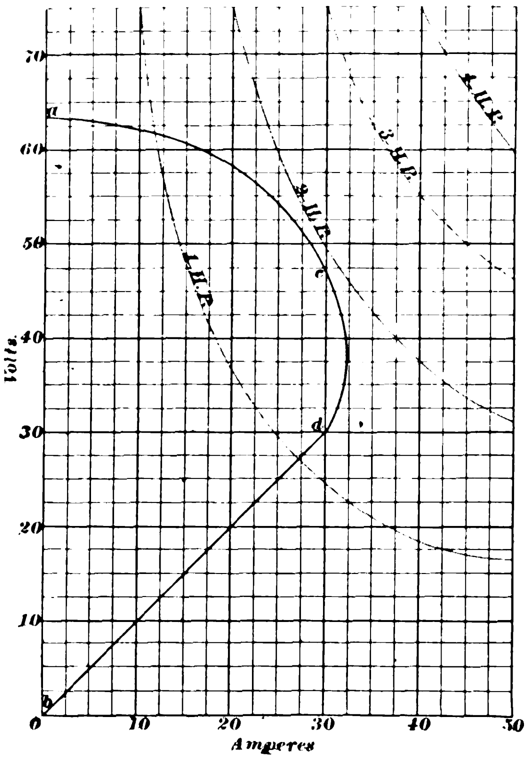


Fig. 30.

rated pressure of 63.5 volts at no load; 63.5 volts will then approximately be the maximum pressure this machine is capable of developing, since all of the current generated when the main circuit is opened passes through the field circuit. The current in the main circuit is, of course, zero, so upon a piece of co-ordinate paper ruled vertically and horizontally as in Fig. 30, these values should be plotted. It is customary to use the vertical lines or ordinates for representing the voltages, and the horizontal lines or abscissæ for representing the currents obtained in the test. Having assigned convenient values to the divisions on the co-ordinate paper for the case at hand, the plotting of the values just obtained (63.5 volts, 0 amperes) will give the point *a*. The iron plate of the rheostat should then be lowered so as to project an inch or so into the solution, and a second set of readings taken with the speed at its normal value and the rheostat in the position given it for the previous reading. Suppose the deflections on the meters when corrected by aid of the constants or curves of the meters as the case may be, give 62.5 volts and 7.5 amperes; the plotting of these values will give another point for the curve. A still further lowering of the plate will permit a stronger current in the main circuit, and the value of this together with its corresponding voltage will give a third point for the curve. Neither for this reading, however, nor for the following readings of the test should the field rheostat be altered. When six or eight points ranging from zero to a maximum current have been obtained and plotted, a curved line should be drawn through them such as shown at *a c d b* in Fig. 30. This line is the characteristic curve of the machine tested, and while it may be sketched in free-hand it should preferably be drawn by the aid of French curves.

An examination of the characteristic curve here presented for the shunt generator, shows that the highest point of the curve occurs at no load or 0 amperes, that as the current is increased the voltage drops first slightly to the point *c*, and then rapidly until the point *d* is reached when any further lowering of resistance in the main circuit to increase the current causes not only a rapid decline in the voltage but also of the current until both voltage and current become approximately zero. In some machines a very slight current results even when the terminals of the machine are actually short-circuited, that is due to residual magnetism in the pole pieces, so that the lower portion of the curve often terminates not exactly at zero but at a point some distance along the current line. The working portion of the curve is from *a* and *c* at which time the machine is supplying a fairly constant voltage. From *c* and *d* shows a critical condition of affairs, while the straight portion *d b* represents the unstable part of the curve caused by the field current being below its proper value. The position of the point *c* determines the maximum power the machine is capable of developing, being in the case cited 47.5 volts and 30 amperes. This is

$$\frac{47.5 \times 30}{746} = 1.91 \text{ hp.}$$

In order to tell at a glance the approximate amount of work a generator is performing at any given output or load, it is often convenient to draw on the co-ordinate paper certain horse power lines as has

been done in Fig. 30. The manner in which they are determined is simple. The 1 hp. line represents 746 watts; therefore, if a certain number of amperes represented on the abscissæ line be divided into 746 the result will be the number of volts which, if plotted above the value of amperes selected, will give one point on the 1 hp. line Other points obtained in the same manner determine the course of this line. The same method is followed for the 2 hp. line except in place of dividing into 746, twice 746 or 1,492 is used, and for the 3 hp. line three times 746 or 2,238 is the dividend.

The general form of characteristic curve that may be expected from a series generator is shown at *o a* in Fig. 31. It is obtained

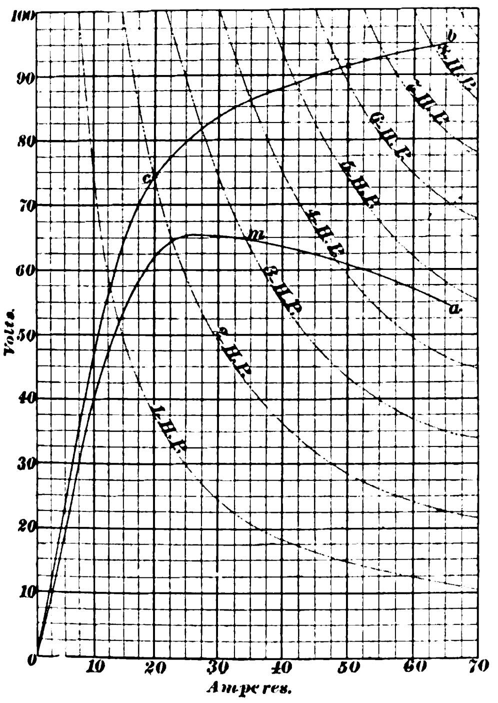

FIG. 31.

practically in the same manner as previously described for ascertaining the data for the shunt characteristic curve, except that no field rheostat is employed. Commencing with no load or amperes, that is, with the iron plate of the water rheostat raised out of the contents of the iron tank, there will probably be a small deflection noticeable on the voltmeter. At first thought, one would suppose that since the main circuit is open there would be no current through the field winding and therefore no voltage at this point, but if the reader bears in mind that there is always more or less residual magnetism in the magnet poles of a generator after once in service, he can readily account for the few volts noticeable. Whatever this reading may be, it should be recorded and plotted as in Fig. 31. Then the iron plate should be lowered so as to project slightly into the salt solution and the next set of readings taken and plotted, and so on as in the case of the shunt generator. The curve *o a*, Fig. 31, which represents this procedure for a certain series generator is practically a straight line at the beginning, representing thereby a proportional increase of voltage with increase of current, but after a certain current is reached (about 20 amperes for the machine here depicted) the curve flattens and takes a downward direction.

The turning point occurs in the characteristic curves of all series generators, and it denotes the stage at which the iron magnet cores become so saturated with lines of magnetic force that they will not readily allow more to pass through them; this turning point is technically known as the point of saturation, and the current corresponding (20 amperes in this case) is called the critical current of the generator. The point of saturation in any given series machine is governed by the amount of iron in the magnetic circuit; its position in the curve therefore varies according to the design of the generator as does also the critical current. The value of the latter is important inasmuch as the valuable features of a series generator assert themselves only when the machine is supplying a greater number of amperes than that of the critical current, for if the series generator be worked along that part *m a* of the curve to the right of the point of saturation it becomes nearly self-regulating as regards current, because as the current increases the voltage drops.

In Fig. 31 in addition to the characteristic curve *o a*, which may more definitely be called an external characteristic curve on account of representing the conditions external to the generator, there is shown a total characteristic curve, *o c b*. The latter curve represents the relation between the current and the total voltage developed in the armature, and may be plotted from the external characteristic curve if the resistance of the armature between brushes and the resistance of the series field winding be known. For example let us assume these combined resistances amount to .6 ohm. At 30 amperes there would be required $30 \times .6 = 18$ volts to force this current through the armature and field windings. At 30 amperes the external pressure is 65 volts, as shown by the curves *o a*; the total voltage developed for 30 amperes is, therefore, the external voltage plus the internal voltage or $65 + 18 = 83$ volts. Plotting 83 volts for 30 amperes will give one point for the external characteristic curve of this machine, and by determining in like manner the total voltages developed for six or eight different currents over the scale, sufficient data will be at hand for plotting and drawing in the curve *o c b*. Horse power lines have also been drawn in Fig. 31 according to the method already described. From these it is seen that the generator develops about 2 hp. at 20 amperes, about 4 hp. at 35 amperes, and about 7 hp. at 55 amperes.

The characteristic curve of a compound generator, if over-compounded, follows the general trend of that shown in Fig. 32 at *a b*, which curve was obtained from a machine over-compounded from 118 to 123 volts, and designed to give 203 amperes at full load. The preliminary arrangements for this test are similar to those for a shunt generator, and if the shunt across the series field winding is already made up and in position, the readings are taken precisely in the same manner. It is generally considered sufficient if observations are recorded at 0, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$ and full load. If it is desired to ascertain the effect which residual magnetism has upon the field magnets, the current is decreased after the full load point is reached without opening the circuit, and readings are taken in succession at $\frac{3}{4}$, $\frac{1}{2}$, $\frac{1}{4}$ and 0 load. This was done in the case illustrated in Fig. 32, and the readings plotted gave the curve *b c d e s*. It is thus seen that residual magnetism exerts no small effect upon the voltage obtained at the different loads, for had there been no residual magnetism in the field magnets the curve *b c d e s* would have coincided with the curve *a b*. The curve *a b*, and the straight line *a x* drawn through the points *a* and *b*, are almost identical, and as *a x* respresents the theoretical characteristic curve for the machine, it is seen the compounding is practically perfect. In order to insure such accurate results being obtained, providing the machinery is correctly designed, requires considerable care in taking the readings; for example, each step or load on the ascending curve should not be exceeded before the corresponding deflection is taken, else the residual magnetism will cause the reading to be higher than it actually should be, and the following readings will also be affected in the same manner.

In case the shunt to be employed across the series field has not been made up, it is advisable to perform a trial test before taking the readings for the curve as previously described. The trial test consists in taking two readings—one at no load and the other at full load—the shunt being so adjusted as to length and section that the desired amount of compounding will be obtained in the latter reading with normal voltage at no load. If the first trial fails to produce the desired result by

giving too low a voltage at full load, the length of the shunt across the series field should be increased, or its section should be reduced by employing a less number of strips in its makeup; on the other hand, if the voltage at full load is higher than that desired, there must be made a decrease of length or an increase of section in the shunt employed. After each full load reading in this trial test it is necessary to entirely remove the load and then open the shunt field circuit in order to eliminate both the effects of residual magnetism and obtain the rated or normal voltage at no load for the following test.

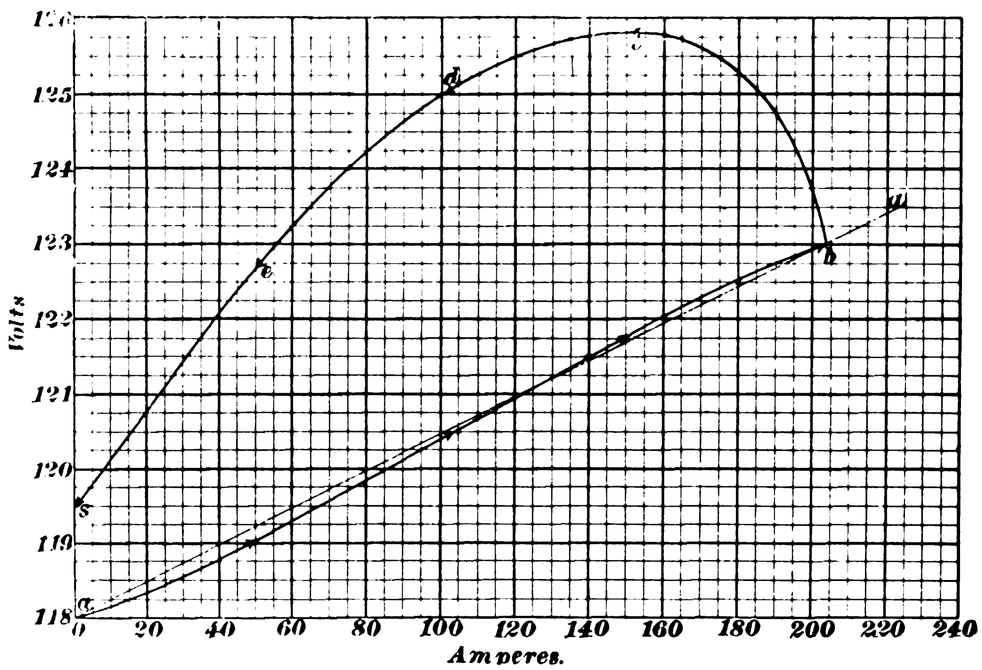

FIG. 32.

FURNISHING TIME BY TELEGRAPH.

One of the important functions of the United States Naval Observatory, located at Washington, D. C., is the furnishing of standard time to the country at large through the medium of the telegraph. During the last fiscal year the time service sent regularly daily telegraphic time signals at noon, 75th meridian time, with an average error for the year of only 0s.15. The widespread importance of this service is shown by the fact that it furnishes absolute standard time not only for navigators at all the principal seaports, but for the entire country except the Pacific coast, which gets a similar signal from the Naval Observatory at the Mare Island, Cal., Navy Yard. Moreover, all of this invaluable service is rendered the country at no expense whatever to the Government, inasmuch as it is merely incidental to the work, and the facilities required for the rating of chronometers for naval vessels.

To illustrate the wide distribution of this time signal, it is of interest to record the fact that it goes out daily over the wires of the Western Union, the Postal Telegraph, the American Telephone & Telegraph Company, the electrical department of the District of Columbia, and the National Electric Supply Company. There are now 18 Government time-balls and some 40,000 public and private clocks corrected daily by naval time signals. The wires of the American Telephone & Telegraph Company and of the electrical department of the District of Columbia were connected during the past fiscal year, and an arrangement has been made, by means of an electric sounder in the telephone room, to give the exact time by telephone any time of day or night to anyone who calls up the Observatory.

Shortly before New Year's Day a suggestion was made to the telegraph companies that they transmit the usual series of signals to end at midnight and thus announce the exact moment of the beginning of the new year. The Western Union took up the matter with great interest and energy, and the series of signals was sent out at midnight, 1, 2 and 3 A.M., so that each great section of the country might get its own midnight signal direct from the Naval Observatory at Washington. The plan was carried out very successfully and elicited so much general interest that it seems advisable to repeat it every New Year's eve hereafter, and officials of the Naval Observatory have further recommended that an effort be made, by eliciting the co-operation of other telegraph and cable companies, to send it all over North and South America, to our most distant colonies, and perhaps around the world, wherever telegraphs and cables extend and the necessary co-operation can be secured.

The receipt of the midnight signal was accurately timed at the Lick Observatory in California, and a report made to the Naval Observatory in Washington showed that it took but 0s.06 in transmission. The fact that this suggestion by the Observatory was taken up so willingly and the results greeted with such enthusiasm shows how strongly it appealed to the sentiment of the country, and if such sentiment be strong enough to enlist the co-operation of telegraph and cable companies to send similar signals around the world next New Year's eve, it seems well worthy of the slight trouble required on the part of the Observatory. Although such signals cannot be transmitted automatically from land lines to long cable lines, and vice versa, yet with expert manual transmission there need be little or no delay, and barring accidents, the midnight signal could doubtless be sent around the world and back to the Observatory in a very few seconds of time. Such a New Year's greeting from Washington to the entire civilized world, sent out officially, but carried everywhere by public-spirited co-operation of private companies, would have a powerful, even if only sentimental, influence.

A similar experiment was tried at 9 P.M. on June 15 last, upon the occasion of the visit of the executive board of the Observatory, in order to illustrate the possibilities of the time service as perfected by the Observatory in co-operation with the Western Union. The signals were sent all over the United States and even beyond its limits, to Toronto, the City of Mexico, Havana, and thence to San Juan and Kingston, Jamaica. A report from the Toronto Observatory the following day stated that it was timed there, and agreed within 0s.20 of their standard clocks. This experiment, together with the fact that our daily noon signals are now sent regularly to Havana over the short cable from Key West, shows that time balls can be established at all of our naval stations in the West Indies and dropped regularly by the noon signal from the Naval Observatory.

Wireless Telegraph With Port Arthur.

It is understood that negotiations are about to begin through Pekin for the purpose of arranging wireless telegraph communication with Port Arthur from a small rocky island off Cheefoo, which was acquired by France after the war of 1884-85, in which France, Great Britain and China were involved.

STANDARD PRACTICE IN THE USE OF ALTERNATING CURRENT ELECTRICAL APPARATUS.*

BY J. J. GIBSON.

(*Continued from page 179.*)

Let us now turn to the electric system. The alternators must run at absolutely the same velocity since they are in parallel, but the electric circuit by which they are connected has an elasticity similar to the elasticity which I spoke of in the shaft in Fig. 2. This permits of the two armatures differing slightly in angular position, but when in such a position currents flow from one machine to the other, which tend to pull the lagging machine up to the mean position, and we have the same process of transmission of load and the possibility of oscillation as we had in the mechanical analogy. A mechanical analogy has been used in order to show that the problem is purely a mechanical one, for the alternators create no power; they simply transform and transmit the power which they receive. If they give varying power to their circuits it is because they are receiving varying power from the engines which drive them.

Let us now consider the engine requirements which are necessary to prevent the troubles pointed out.

First—The engine governor should be so constructed that there is no tendency to cause this periodic transfer or surging of the load between one engine and another. All reciprocating engines have an angular variation of velocity in different parts of the revolution. Either this or a sudden variation of load will affect the governor, or other causes may lead to non-uniformity of speed. The engine governor should not be sensitive to such disturbances. It should not maintain or increase them. The effect of periodic transfer of load occasioned by hunting, caused by two engines running in parallel, is somewhat similar in effect to throwing the load on or off of a single engine at short, equal intervals measured by one or several pulsations in the combined turning efforts applied to an engine shaft. The point is that, in case of pulsating load, the engines must not tend to accentuate the pulsations in turning effort and speed.

Engine governors may be made to meet these requirements in some cases by the application of dash pots, so that there is resistance to any very sudden movement of the governor, although if the tendency to move is continued for a sufficient length of time the resistance of the dash pot is lessened and the movement rendered possible. On the other hand, under certain conditions, dash pots are not necessary. The period of the governor may be changed by changing the value of the adjusting weight and its distance on the lever, thus retaining the same moment but changing the moment of inertia and consequently the natural period of the governor.

In engines of large size governors are very frequently furnished with a simple reversing motor of the direct current type, which is arranged to screw up or down a spring attached to the governor weight, the motor being started, stopped or reversed from the switchboard by a simple switch. This permits bringing an unloaded unit up to speed so as to throw it in parallel with loaded units and afterwards enables the control of speed so that the unloaded unit can assume its share of the load after being put into speed. It also permits of relieving a unit of a load so that it may be put out of service.

On account of the impossibility of predicting the conditions in practice in any installation, the engine governor should be readily adjustable.

Second—The variation of the rotating part of the generator through a revolution at any constant load not exceeding 25 per cent. overload, should not exceed one-sixtieth of the pitch angle between any two consecutive poles from the position it would have if the motion were absolutely uniform at the same mean velocity. The maximum permissible variation, i. e., the amount the rotating part forges ahead plus that which it lags behind the position of uniform rotation is one-thirtieth of the pitch angle between two poles. In a 2-pole machine this variation is equivalent to 3 degrees as measured on the circumference of the rotating part. In the 4-pole it is 1½ degrees; in a 6-pole machine 1 degree. The greater the number of poles the smaller the permissible angular variation. Incidentally it follows that the lower the frequency of the machine the better the conditions for parallel operation. This requirement of uniform rotation is usually obtained by the use of a heavy fly-wheel. Too great weight in a fly-wheel is not a good thing, for it adds to the pendulum effect by causing the governor to act longer than it should. The engine fly-wheel, therefore, should be no heavier than is necessary. Multi-crank engines, by reason of the fact that there are more impulses per revolution, give more satisfactory conditions. Of two crank engines the twin engine, non-compound in parallel, operates most easily. A cross-compound engine cannot be made to accurately divide the load between the two cylinders over wide ranges. It is, therefore, more difficult to operate than the twin engine, but it is a type which does not require an excessive fly-wheel and is much better than the tandem compound. Vertical engines require larger fly-wheels than the horizontals on account of irregularity in the forces producing rotation introduced by the weights of reciprocating parts.

But as we go on to three crank engines steam distribution introduces complications, although we are increasing the impulses per revolution. An engine which is giving excellent results is the double horizontal vertical engine, giving eight impulses per revolution. This type of engine is used in the 5,000 kw. units in the power house of the Manhattan Railway, New York City.

Third—Similar characteristics of speed regulation are essential in the engines, so that their respective generators may properly divide the load. It is better, therefore, that the speed should drop from 3 to 5 per cent. from full load to no load than there should be very close regulation, such as 1 to 2 per cent. A diagram will illustrate this point. Referring to Fig. 3, let us lay off loads on

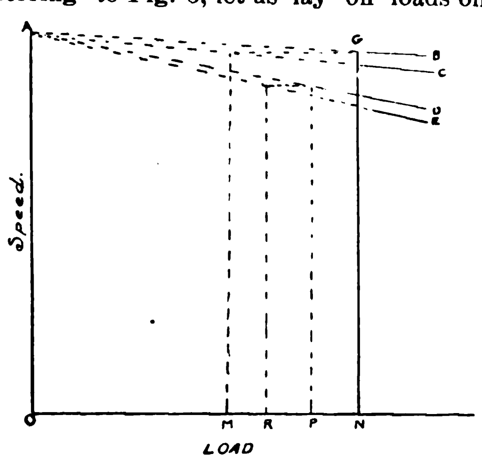

FIG. 3.

horizontal axis and speeds on a vertical axis. We will let the line A-B and the line A-C be the speed characteristics of two engines. We will say that at the load corresponding with the point N on each engine that the difference in speed corresponds to the vertical distances between the characteristic lines, as measured on the line G-N. Now the engines must run at the same speed since their alternators are in parallel; therefore, when the engine corresponding to the line A-B is carrying the load corresponding to O-N, the engine represented by the characteristic A-C is bound to be carrying the load corresponding to O-M.

Let us now suppose that both engines

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

have a greater drop in speed from no load to full load and that the new characteristics be the lines A-D and A-E. As before, one has a slightly greater drop than the other in speed for the same load, but since they must run at the same speed, the load in this case divides itself as shown, the engine corresponding to characteristic A-D carries a load corresponding to O-P; the engine corresponding to the characteristic A-E carries the load O-R.

This diagram, therefore, illustrates the fact that the distribution of load would be more even between the engines having the greater drop in speed than between the engines having the smaller drop in speed.

(*To be continued.*)

INTERNATIONAL ELECTRICAL CONGRESS RECEPTION COMMITTEE.

The first meeting of the International Electrical Congresss Reception Committee of the American Institute of Electrical Engineers was held at 12 West 31st street, Thursday evening, March 24. A large representation of the committee was presented, also Mr. George G. Ward, local honorary secretary of the Institution of Electrical Engineers, members of the board of directors, and members of the transportation committee, who had been invited to attend.

Chairman Lieb proposed the itinerary for the tour of the European visitors.

The details of the tour as suggested were thoroughly discussed, and while there was a feeling that it would be a severe tax upon the visitors, it was difficult to see how the trip could be curtailed without omitting some desirable and important features.

In the course of the discussion it was pointed out that possibly some arrangement could be made by which those who desired to extend their trips beyond St. Louis, or spend a longer period at the Exposition, would be able to return independently upon the regular excursion ticket that will be provided. It was accordingly voted that the committee be thanked for the programme as outlined, and that it be accepted with the recommendation that, if possible, the chairman of the transportation committee should arrange that there be some plan adopted by which as many sleeping cars as might be necessary would be provided for the special train on the return trip, and that such persons as desired have the privilege of alternative return routes on regular trains. In case this cannot be arranged, the plan to be adopted is as presented below.

The following executive committee was appointed: John W. Lieb, Jr., chairman; Frank J. Sprague, vice-chairman; J. C. Barclay, J. J. Carty, F. W. Jones, H. Ward Leonard, E. H. Mullin, L. B. Stillwell, H. G. Stott, Calvert Townley, Gerge G. Ward, J. G. White.

Local committees at the various points to be visited will be subsequently announced by the chairman.

THE ITINERARY.

The foreign guests of the Institute, including the British Institution of Electrical Engineers, who are the official guests of the American Institute of Electrical Engineers, the representatives of the Associazione Elettrotecnica Italiana and representatives of other foreign technical bodies and unattached delegates, are expected to arrive in New York previous to September 3. After this date the itinerary will be as follows:

Sunday, September 4, New York City—This day will be spent in a steamer ride up the Hudson River, possibly as far as West Point, giving the visitors an opportunity of seeing the beauties of the river and the surroundings of New York City.

Monday, September 5—The visitors will be entertained by the corporations representing the electrical industries of New York City, including a visit to the power houses of the Rapid Transit Subway Company, the Manhattan Railway Company, the Metropolitan Street Railway Company, the New York Edison Company, the exchanges of the New York Telephone Company and other points of engineering interest. In the evening there will be a formal reception of the foreign visitors under the auspices of the American Institute of Electrical Engineers.

Tuesday, September 6, Schenectady, N. Y.—The party will leave New York on Tuesday morning for Schenectady, where they will be received and entertained by the General Electric Company, leaving for Albany in the afternoon; leave Albany in the evening for all-night trip to Montreal.

Wednesday, September 7, and Thursday, September 8, Montreal, Canada—Reception at McGill University, and visits to the important power transmission plants in the vicinity, leaving Montreal Thursday evening by boat or train for Niagara Falls.

Friday, September 9, Niagara Falls, N. Y.—Visit to the Falls and the important power houses and electrical industries of the locality. Leave Niagara Falls Friday evening for Chicago, arriving Saturday morning,

Saturday, September 10, Chicago, Ill.—Visits to important power houses and local points of interest. Leave Chicago Saturday evening for St. Louis, traveling all night.

Sunday, September 11, St. Louis, Mo.—To be spent in St. Louis resting, etc.

Monday, September 12—Opening of the International Electrical Congress at 10 o'clock A.M., with joint sessions of all of the sections.

Wednesday, September 14—Special joint session between the American Institute of Electrical Engineers and the British Institution of Electrical Engineers, to which all foreign guests are invited.

September, 13, 14, 15 and 16.—Sessions of the various sections of the Congress with sessions each day from 9 to 12 A.M., and from 1:30 to 4:30 P.M,

Saturday, September 17—Closing general sessions in the afternoon of all sections of the International Electrical Congress. Leave St. Louis during night for Pittsburg, arriving late Sunday afternoon.

Monday, September 19, Pittsburg, Pa.—Reception and entertainment by the Westinghouse Company, and visits to important and interesting local industries. Leave Pittsburg Monday night and arrive at Washington Tuesday morning.

Tuesday, September 20, Washington, D. C.—Inauguration of the National Bureau of Standards at Washington and visits to places of local interest.

Wednesday, September 21, Philadelphia, Pa.—Visits to important power houses and points of interest. Leave Philadelphia for Boston in the afternoon via boat, Fall River Line.

Thursday, September 22, Boston, Mass.—Visits to power houses, Harvard University, Massachusetts Institute of Technology and places of local interest. Leave Boston Thursday night for New York, by boat.

Friday, September 23—Unassigned.

Saturday, September 24—Return home by some of the party.

False Report About a Municipal Plant.

Editor ELECTRICITY.

SIR: We notice in the issue of your valuable publication of March 23, under "Lighting" on page 167, an item in reference to Hancock, Mich., as follows: "The citizens voted favorably on the proposition to build a municipal electric light plant next month." Of course, we do not know the source of your information, but the information given in the

item referred to is a long way from the truth. There was, some time ago, a petition presented to the city council of Hancock, which was signed by a local labor union to put the question to a vote of the people on April 4, which is the annual election. No action was taken on this petition and the election warrants, already posted, do not contain anything referring to a municipal plant.

Yours very truly,

HOUGHTON COUNTY ELECTRIC LIGHT CO.

Houghton, Mich., March 29, 1904.

American Institute Officers.

The board of directors of the American Institute of Electrical Engineers, at the last meeting in this city, placed in nomination the following ticket containing the names of the proposed officers to be voted on at the annual meeting in May:

For president—John W. Lieb, Jr., New York.

For vice-presidents—W. E. Goldsborough, St. Louis; John J. Carty, New York; Samuel Reber, Washington, D. C.

For managers—Henry G. Stott, New York; Louis A. Ferguson, Chicago; J. G. White, New York; S. S. Wheeler, Ampere, N. J.

For treasurer—George A. Hamilton, New York.

For secretary—Ralph W. Pope, New York.

The directors' nominations are usually equivalent to an election.

Standard Underground Company's St. Louis Office.

The Standard Underground Cable Company announces the recent opening of a branch office or headquarters in the security Building, St. Louis, Mo., in charge of Mr. W. A. Caldwell, who was formerly connected with the Chicago office of the company, but more recently with the home office at Pittsburg. Mr. Caldwell had a number of years' experience with the company in both the construction and sales departments.

This enterprising company has now seven district or branch offices throughout the country, covering the whole of it from Maine to California, namely: Northeastern sales department, Delta Building, Boston; Eastern sales department, 56 Liberty street, New York City; Southeastern sales department, Betz Building, Philadelphia; Central sales department, Westinghouse Building, Pittsburg; Western sales department, Rookery Building, Chicago; Southwestern sales department, Security Building, St. Louis, and the Pacific Coast sales department, Crossley Building, San Francisco.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MARCH 29, 1904.

Electric Railways and Appliances.

755,770. Traction-Engine Wheel. Amos Harrold, Newark, O. Filed Nov. 11, 1903.

755,788. Car-Fender. Albert E. McLean, Toronto, Can. Filed Dec. 30, 1903.

755,794. Fender. Charles H. Root, Cleveland, O. Filed Aug. 3, 1903.

755,822. Train-Control System. George P. Whittlesey, Washington, D. C., assignor to the General Electric Company. Filed Sept. 26, 1902.

755,825. Railway-Brake Apparatus. Granville T. Woods and Lyates Woods, New York City, assignors, by direct and mesne assignments, to the Westinghouse Electric & Manufacturing Company, Filed Dec. 31, 1902.

755,872. Car-Fender. James T. Heron and John J. Crowley, New Bedford, Mass. Filed Jan. 6, 1904.

755,899. Electric-Railway System. Timothy Mahoney, San Francisco, Cal. Filed April 20, 1903.

755,905. Electric-Traction System for Railways. August Meuschel, Montreal, Can. Filed May 4, 1903.

755,999. Electric-Trolley Head. John T. Cherry, Plymouth, and Edward H. Clive, Devonport, Eng. Filed Nov. 3, 1902.

756,060. Car-Fender. Frank A. Schaaf, Cleveland, O. Filed March 14, 1903.

756,156. Signal Apparatus for Trolley-Railways. Almo L. Cheatham, Louisville, Ky., assignor of three-fourths to Robert V. Cheatham, same place. Filed Aug. 8, 1903.

Electric Lights and Appliances.

755,697. Electric-Incandescent-Lamp Socket. Guy H. Proctor and John B. Daley, Somerville, Mass., assignors to the New England Electric Manufacturing Company, same place. Filed July 30, 1903.

755,797. Arc-Lamp Hanger. Howard R. Sargent, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 2, 1902.

755,815. Electric-Arc Lamp. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed Aug. 19, 1901.

755,855. Globe-Holder for Arc-Lamps. Samuel E. Doane, Cleveland, O., assignor to the Fostoria Bulb & Bottle Company, Fostoria, O. Filed June 24, 1903.

755,914. Means for Adjusting Lamps. Walter G. Morse, Waterbury, Conn. Filed Nov. 7, 1903.

755,954. Electric Lamp and Socket. Albert N. Soden, Trenton, N. J. Filed Dec. 10, 1902.

756,025. Electric-Light-Circuit Protector. Stanley Kalbach, Wildwood, N. J. Filed May 12, 1902.

756,049. Switch for Incandescent Electric Lamps. Conrad M. Pitel, Meriden, Conn. Filed Nov. 23, 1903.

756,050. Coupling for Incandescent Electric Hanging or Suspension Lamps. Conrad M. Pitel, Meriden, Conn. Filed Nov. 23, 1903.

756,117. Electric-Lamp Support for Convertible Signal-Lanterns. Louis H. W. Kerber, Chicago, Ill., assignor to the Adams & Westlake Company of Illinois. Filed May 13, 1903.

Electrical Machinery and Apparatus.

755,635. Transmission Mechanism. George Dillig and Henry P. Dillig, Millvale, Pa. Filed May 8, 1903.

755,731. Controller for Electric Motors. Magnus W. Alexander, Lynn, Mass., assignor to the General Electric Company. Filed June 13, 1903.

755,732. Electric Motor. Ralph E. Barker, Lynn, Mass., assignor to the General Electric Company. Filed Aug. 7, 1903.

755,733. Motor. Thomas Barrow, Plainfield, N. J., assignor to the Pedrick & Ayer Company, same place. Filed Jan. 8, 1903.

755,739. Maximum-Demand Indicator. Harry W. Brown, Boston, Mass., assignor to the General Electric Company. Filed Aug. 2, 1902.

755,744. Controller. Frank E. Case, Schenectady, N.Y., assignor to the General Electric Company. Filed Oct. 1, 1902.

755,750. Emergency-Brake. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed July 16, 1903.

755,751. Motorman's or Engineer's Valve. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 13, 1903.

755,757. Multiple-Rate Meter. Alexander J. R. Fiego, Lynn, Mass., assignor to the General Electric Company. Filed July 21, 1903.

755,766. Transformer. Walter A. Hall, Lynn, Mass., assignor to the General Electric Company. Filed Sept. 29, 1902.

755,771. Electric Switch or Circuit-Breaker. Edward M Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Filed Jan. 29, 1900. Renewed May 7, 1902.

755,791. Means for Closing Field-Circuits of Rotary Converters. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 17, 1903.

755,817. Electrical Igniting Mechanism for Explosive-Engines. Daniel M. Tuttle, William H. Lindley and William H. Tuttle, Canastota, N. Y. Filed Oct. 27, 1902.

755,819. Induction Motor. Pendleton G. Watmough, Jr., Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 2, 1902.

755,824. Means for Starting Alternating-Current Dynamo Electric Machines. Jonathan E. Woodbridge, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 11, 1901.

755,827. Rheostat. William C. Yates and Paul Zimmer, Schenectady, N. Y., assignors to the General Electric Company. Filed July 25, 1903.

755,828. Rheostat. William C. Yates, Schenectady, N. Y., assignor to the General Electric Company, Filed Aug. 22, 1903.

755,829. Controlling Induction Motors. Arnaldo P. Zani, Milan, Italy, assignor to the General Electric Company. Filed June 30, 1900.

755,845. Electric Time Switch. Frank W. Cherry and Henry F. Radke, San Francisco, Cal. Filed Jan. 25, 1902.

756,026. Insulator. William S. Kinsley and Stewart S. Bell, Reading, Mass. Filed Aug. 10, 1903.

756,045. Shunt Controller for Electric Machines. Nels O. Nelson, Chicago, Ill. Filed July 13, 1903.

756,167. Controlling Electric Boosters. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Original application filed Aug. 31, 1900. Divided and this application filed Oct. 20, 1902.

756,181. Insulator. Louis McCarthy, Boston, Mass. Filed Feb. 11, 1904.

Telephones and Telephone Apparatus.

755,691. Telephone Selective System. Noble S. McKinsey and Anton R. Nelson, Susanville, Cal. Filed June 15, 1903.

755,868. Telephone System. Robert Hamilton, Milton, Mass. Filed Feb. 7, 1903.

756,091. Telephone Cabinet. William B. Altick, Lancaster, Pa. Filed May 16, 1902.

756,183. Telephone Call Attachment. Jason J. Nye, Brookfield, Vt. Filed March 31, 1903.

Miscellaneous.

755,642. Electric Accumulator Plate. Chaimsonovitz P. Elieson, Paris, France. Filed Oct. 16, 1903.

755,646-755,647. Multiplex Telegraphy. Stephen D. Field, Stockbridge, Mass. Filed March 5, 1903; March 24, 1903.

755,659. Electric Water Heater. James F. Hathaway, San Francisco, Cal., assignor of two-thirds to Felix B. Mulgrew and Julius M. Alexander, same place. Filed Aug. 10, 1903.

755,669. Current Selector for Charging Secondary Batteries. Miller R. Hutchison, New York City, assignor, by mesne assignments, to the Hutchison Acoustic Company. Filed May 5, 1903.

755,740. System of Electrical Distribution. Harold W. Buck, Niagara Falls, N. Y., assignor to the General Electric Company. Filed Sept. 4. 1902.

755,774. Electric Clock. Frank Holden, London, Eng., assignor to the General Electric Company. Filed April 16, 1900.

755,775. System of Electrical Distribution. Lewis L. Holladay, Lynn, Mass., assignor to the General Electric Company. Filed Aug. 21, 1902.

755,782. Electrical Contact Device. John Lindall, Boston, Mass, Filed Oct. 8, 1903.

755,783. Electric Fire Alarm. August Lueckert, St. Louis, Mo. Filed Dec. 10, 1902.

755,830. Tub for Electric Baths. Josef Zwiebel, Neu-Ulm, Germany. Filed Nov. 24, 1903.

755,840. Detector for Electrical Disturbances. Jagadis C. Bose, Calcutta, India, assignor of one-half to Sara Chapman Bull, Cambridge, Mass. Filed Sept. 30, 1901.

755,853. Electric Power Transmission System. Max Deri, Vienna, Austria-Hungary, assignor to the Stanley Electric Manufacturing Company. Filed May 28, 1902.

755,890. Electric Signaling Device. Thomas C. Laney, Toledo, and Charles S. Longnecker, Delta, O. Filed Nov. 24, 1902.

755,897. Electric Lock. Frank Lombardi, Brooklyn, N. Y. Filed Dec. 19, 1903.

756,119. Electric Resistance. Hans von Kramer, Bath, Eng. Filed Sept. 1, 1903.

756,176. Protective Sheath or Envelop for Storage Battery Plates. Achille Meygret, Paris, France. Original application filed June 29, 1903. Divided and this application filed July 27, 1903.

THE TELEPHONE WORLD.

Cut In Bell Rates Will Not Affect Cuyahoga Company.

The announcement made by the Cleveland, O., Telephone Company, that it contemplates a reduction of the rates on the measured service, did not create any excitement in Independent telephone circles; however, it is taken that the Cleveland Telephone Company has, by this arrangement, made a bid for telephone service and change of rates with equanimity. President Dickson, of the Cuyahoga Company, says:

"This lowering of rates will not affect our recently issued schedule in the least. We expect to do an increased business steadily, regardless of the cut in traffic on the part of the opposition. The evidences are that the Cuyahoga Company is now in position with its improved equipment to afford strong competition to the Bell people here and they are getting scared. They have, however, begun at the wrong place to do us any damage. The only concessions they have made is on measured service. On their unlimited service the rates are the same as they have been for years past. Our limited service rates are still lower than theirs and our unlimited service rates are much lower than those offered by our competitors. Of course, under the circumstances, this will not necessitate that we make any change in our rates to meet the competition."

The new schedule of rates is as follows: To business houses one party rate of $15 per quarter for 300 calls, with a rebate of $1.50 for prompt payment; two-party line for $12, with a rebate of $1.50 for prompt payment, including 225 calls. For residences, one-party rate of $11.25 for 200 calls, with a rebate of $1.50 for prompt payment; a two-party line for $9 per quarter for 150 calls, with a rebate of $1.50 for prompt payment.

Each telephone company in St. Louis, Mo., has a World's Fair exchange. The Kinloch has eight trunk lines from the World's Fair to the city, and the Bell has ten. There are 68 telephones on the Bell exchange and 87 on the Kinloch, all the telephones being located in the Administration Building and on the grounds. Communication between different offices of the Fair is without the use of trunk lines, and the congestion on these is due solely to business from without.

The board of public works of Kansas City, Mo., has issued orders to the city treasurer to refund to the Home Telephone Company the $40,000 deposited by it as a guaranty that it would build and operate a telephone system in accordance with the terms of its franchise. City Electrician Haldeman and City Engineer Pike, who inspected the plant of the company, reported that the terms of the franchise had been complied with.

We are requested to publish the election of officers of the Adamsville, O., Telephone Company, as follows: President and manager, J. B. Rhodes; vice-president, C. H. Hanks; secretary, F. P, Winn; treasurer, M. F. Tomlinson; counsel, S. M. Winn.

The Carney Automatic Telephone Company of Carney, Okla., has been incorporated with a capitalization of $10,000.

Telephone Magnates Hold Meeting in Syracuse, N. Y.

Representatives of nearly all of the largest operating telephone companies in New York State were present at the annual meeting of the executive committee of the New York State Telephone Association held recently in Syracuse. The officers of the association are George R. Fuller, of Rochester, president; Howard Hendrickson, of Albany, vice-president; J. H. Scofield, of New York, second vice-president; Joseph B. Ware, of Buffalo, secretary and treasurer.

The meeting was called for the purpose of taking up the report of the special tariff committee appointed for establishing a general plan of handling the toll business of the State.

T. S. Lane, of Jamestown, was elected secretary and treasurer to fill the vacancy caused by the resignation of Joseph B. Ware, who has accepted a position in the West.

It was decided to hold the next annual meeting at Buffalo under the auspices of the Frontier, the Interocean and the Consolidated Telephone Companies. A special committee was named to look after the telephone toll service of the State, the idea being the establishment of a State clearing house. The meeting adjourned to convene in Syracuse within a month.

The annual meeting of the Woodsfield O., Telephone Company was lately held. The following directors were elected: J. B. Rhodes, W. E. Mallory, P. E. Fraley, L. E. Stegner and F. C. Huth. J. B. Rhodes was chosen president; W. E. Mallory, vice-president; P. E. Fraley, secretary and treasurer; F. C. Huth, general manager. The capital stock will be increased from $15,000 to $25,000, and a number of extensions and improvements made the coming summer.

A telephone system is to be inaugurated between Redding and Wengler, Cal., on the Big Bend of the Pit River. The line will run by way of Bella Vista and Ingot. A company has been formed with a capital stock of $10,000, with the following directors: Herbert Bass, of Montgomery Creek; Matthew Wengler, of Wengler; W. G. Scott, of Redding, and R. A. Ward and A. Berg, of Round Mountain.

The Wisconsin Telephone Company has submitted to the Milwaukee council a proposition to establish in the city hall a public telephone station. This company is installing telephones on the street corners of Milwaukee.

There are already more than 12,000 stations or telephones in the territory of the Providence, R. I., Telephone Company, and under the new efforts now being made to extend the service the number is increasing rapidly.

The Scotchtown, N. Y., Telephone Company, is a new concern, capitalized at $2,000. The directors are M. H, Santle, of Circleville, and W. R. Rockefellow and A. C. Santee, of Scotchtown.

Contracts for the Hudson River Telephone Company to extend its lines to White Church, N. Y., have been signed.

A telephone company is now established at Mio, Mich., capitalized at $2,000.

Old Rates for Michigan State Company.

William A. Jackson, president of the Michigan State Telephone Company of Detroit, states that it is not the intention of the reorganized concern to raise the rates of service in that city, nor is it the intention to take away from subscribers the privilege of using the old Blake transmitter, which costs but $54 a year if they choose to use it.

"We are merchants," said he, "and are anxious to please our customers. Like the grocer who wants to keep his trade, we much prefer to sell a man fresh eggs that we can guarantee, rather than old eggs which we cannot guarantee. That is why we recommend to everybody that he get the metallic service. It would be better for our subscribers. There would be more uniformity and less criticism of the telephone service. If a person cannot afford to pay the $72 rate, he can still use the so-called message rate, which gives him a certain number of calls per quarter, or he can get the two-party service. In this way he can reduce his telephone expenses to as low as $30 a year."

Western Rural Line.

A meeting of those interested in the extension of the telephone line from Huntsville, Wash., up Sorghum Hollow, was recently held, and they decided to at once construct the link, which will be about four miles north from Huntsville, and will accommodate several farmers. The cost of these lines, including wires, 'phones and labor, will not be over $150. The present line has connection with Waitsburg, Prescott and Alto, and the plan is to make connection with Dixie, where there is already a rural line to Walla Walla. There is also a line connecting with the Whisky Creek section. When the projected connections are made the whole section from Dayton to Walla Walla will be covered with these rural lines.

The Blue Earth County Telephone Company of Lake Crystal, Minn., has filed articles with $25,000 capital stock. Elliott Upson, of Judson, is president, and David E. Bowen, of Cambria, secretary.

Fred Windisch, of Port Clinton, O., has purchased the telephone exchange at Prairie Depot in that State and will remodel it at once.

The Delaware & Madison County Telephone Company has purchased the telephone exchange at Summitville, Ind.

Cornersville, Tenn., is to have a telephone exchange at an early date, a company having been organized at that place.

Telephone Incorporations.

The Conway Rural Telephone Company, Conway, Mo. Capital stock, $10,000.

The Tremont Independent Telephone Exchange, Tremont, Ill. Capital stock, $20,000. Incorporators: Aquilla J. Davis, Frank J. Davis and Walter H. Ames.

The Reading & Rock Stream Telephone & Telegraph Company, Watkins, N. Y. Capital stock, $10,000. Directors: Charles Chapman H. M. Smith and H. S. Howard, of Watkins.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Anderson, Ind.—The city electric light board has negotiated its first loan to pay on the cost of constructing the new electric light plant.

Ann Arbor, Mich.—The Michigan Milling Company has asked for an electric lighting and power franchise. It wants to develop power for commercial lighting.

Bryan, Tex.—The city council has granted to H. B. Dorsay a franchise to erect electric light wires and poles on Main street for the purpose of furnishing to the citizens lights, fans or other electrical appliances.

Chicago, Ill.—E. B. Ellicott, city electrician, asks for $200,000 appropriation for the extension of the municipal electric lighting plant. Many arc lamps would be replaced by city lamps.

Cicero, Ind.—The town board has granted a 25-year electric light franchise to John Plain.

Fairfax. S. D.—C. A. Johnson, president of the Fairfax State Bank, is making arrangements for furnishing the town with electric lights.

Fillmore, Utah.—It is reported that Mr. Winberg, of Milford, will erect an electric light plant here.

Fleetwood, Pa.—The borough council is talking of lighting the village with electric lights.

Fort Wayne, Ind.—The organization of the Fort Wayne Electric Light & Power Company has now been effected and the company will soon begin the reconstruction of the plant.

Ft. Worth, Tex.—Sam Rosen has asked the council for an electric light franchise here.

Glenns Ferry, Ida.—B. G. Mullins and others, of Napa, will erect an electric light and water plant here to cost $25,000.

Grand Rapids, Mich.—The municipal electric lighting plant will probably be enlarged to supply additional light in city buildings. Barney Meyer, superintendent, is interested.

Hamilton, O.—The city council has passed an ordinance for the issuance of $15,000 for a water plant, and $5,000 for electric light bonds.

Harvey, Ill.—The city council has closed a contract for electric lighting with the Calumet Lighting Company of Chicago for five years.

Harmon, Ill.—The electric light plant project is favored by the citizens.

London, Ky.—The London Electric Light Company has been incorporated with R. M. Jackson, president; J. B. Ederline, secretary, and W. F. Remer, general manager.

Minneapolis, Minn.—The Minneapolis Retailers' Association will establish an electric light plant of its own. W. L. Harris is one of the parties interested.

Monterey, Mex.—The Electric Light & Power Company will install machinery so as to double the number of incandescent lights for the city, and add many more arc lights and power for operating innumerable electric fans.

Ontario, Wis.—Herman Timmerman will put in an electric light plant here this summer.

Otsego, Mich.—The proposition to raise $2,500 to purchase the electric light plant was lately carried by a fair majority.

Philo, O.—Hon. C. U. Shryock, of Zanesville, has secured a franchise from this place for an electric lighting plant.

Pinckneyville, Ill.—The electric lighting plant, recently destroyed by fire, may be rebuilt. J. H. Ward is a local stockholder.

Presque Isle, Me.—The electric lighting and heating station owned by the Presque Isle Electric Light Company was lately burned.

Richmond, Cal.—The Richmond Electric Light Company will install a dynamo, also direct generator and motor combined.

San Diego, Cal.—An additional $7,000 has been allowed for the installation of an electric light plant at Fort Rosecrans.

Saybrook, Ill.—The town board has granted a 20-year franchise to Saylor Dres to operate an electric light and heating plant here.

Tallula, Ill.—A new electric light plant is to be installed soon.

Upper Alton, Ill.—An electric lighting plant may be jointly erected by the towns of Upper and North Alton.

Vacaville, Cal.—The matter of erecting an electric light plant is being talked of. F. A. Seiger, city engineer; S. G. Creighton, city clerk.

Victor, Col.—A number of merchants and property owners here have formed a company, which is already backed by nearly $3,000 of pledged capital, and will install an independent electric plant in this city.

Woodbury, Conn.—Work will soon begin on an electric light plant for this city and Pomperaug Valley. The capital stock of the company is $15,000, and the promoters, Judge Warner and E. S. Boyd, are confident that the company will be prepared to install lights early in the autumn of the present year.

Yankton, S. D.—The citizens will soon hold a meeting to discuss the question of lighting.

STREET RAILWAYS.

Anamosa, Ia.—The Chicago, Anamosa & Northern Railway Company will build a new electric line.

Colorado Springs, Col.—The management of the Pike's Peak Cog Road intends to operate the system with electricity in the near future and utilize the natural electrical force that is constantly around the summit of the peak.

Dunkirk, N. Y.—The Buffalo-Dunkirk Electric Company will soon start work on its line.

Escanaba, Mich.—The Escanaba Electric Railway Company is considering the matter of extending its line to Gladstone.

Faribault, Minn.—Donald Grant has plans under way to build an electric car line in this city.

Farmington, Mo.—The St. Francois County Railway Company has absorbed the St. Francois County Electric Railway Company, and will complete the line from Delassus to Flat River via this place.

Ft. Wayne, Ind.—The Ft. Wayne & Wabash Valley Traction Company is making arrangements to establish a line between here and Logansport.

Gulfport, Miss.—Capt. Jones, of the Gulfport & Ship Island Railroad, will build an electric trolley line between here and Biloxi.

Imlay City, Mich.—The proposition is again being discussed here for the extension of the electric car system from Romeo to this place. An effort will be made to secure the $15,000 of stock in the vicinity, which it will be necessary to raise in addition to the right of way and a franchise

Indianapolis, Ind.—Charles H. Henry has asked permission of the county commissioners to build a double-track electric railway along the Churchman Pike.—The Indianapolis & Cincinnati Traction Company is thinking of making extensive improvements here.

Kittanning, Pa.—The Kittanning & Ford City Trolley Railway is to be extended 16 miles from the latter place to Leechburg, where it will connect with the proposed line to Arnold on the Valley road.

Lead, S. D.—A plan for an electric railway between here and the Sundance, Wyo., coal fields, has been projected. It is proposed to build about 40 miles of road passing through Welcome, Wyo., thence to Cyanide. S. D., and this place The promoters are interested in the Economic Power Company, which was mentioned in last week's issue of ELECTRICITY.

Peoria, Ill.—The Illinois Electric Railroad Company, of which U. G. Orendorff, of Canton, is president, proposes to construct an electric line from here to Canton.

Philadelphia, Pa.—The Interstate Street Electric Company, capitalized at $200,000, has been chartered to build a line 20 miles from Port Allegany to Coudersport.

Scranton, Pa.—It is reported here that the Delaware & Hudson Company has decided to equip its line between Carbondale and Wilkes-Barre, a distance of 34 miles, with a third-rail electric system.

Temple, Tex.—Mr. Ahrens, of Reading, Pa., is interested in the proposed trolley line between here and Belton.

Woodbury, N. J.—From recent developments it is believed that the much talked of trolley line from here to Paulsboro will be built this summer.

POWER PLANTS.

Boise, Ida.—The Shoshone Falls Power & Lighting Company will be incorporated with $2,500,000 capital by McDonald & McCoy, of Chicago; Judge Samuel Hughes, of this city, and others. Three plants will be erected, one at Augur Falls, Twin Falls and Shoshone Falls. The plant at the latter place is in course of construction. About 100,000 hp. will be developed by the plants.

Grand Rapids, Mich.—The Cascade Electric Company has been organized, with E. C. Follmer, president. A power plant will be erected on Thornapple River.

Orono, Me.—Preliminary work has commenced at Marshrips on the Penobscot River here for two large concrete dams for a corporation in which William Engel, F. W. Ayers, the Websters and other prominent Bangor lumbermen are interested. It is proposed to utilize this water power formerly used for lumber mills in the generation of electricity for transmission purposes.

Philadelphia, Pa.—Estimates are invited by Dr. Edward Martin, director of the Department of Public Health and Charities, for the erection of a power plant at the new Municipal Hospital on the Macalster farm. Bids will be received until April 11.

San Francisco, Cal.—The Eureka Lighting Company of this city has concluded to begin at once the development of its power water rights on the Trinity River for the purpose of generating electricity for power and light. The rights are sufficient for the production of 6,000 hp., which is at present fully double the amount that can be utilized.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 12⅞@13⅛c.; Lake 12⅞@13⅛c.; casting, 12¾@12⅞c.

Exports of copper aggregated in March over 23,000 tons.

It is reported that the General Electric and Westinghouse Companies will increase the price of lamps 2 cents per lamp.

The New York & New Jersey Telephone Company has declared the regular quarterly dividend of 1½ per cent., payable April 15.

Those best informed on affairs of the Chicago Union Traction Company say dividends on the leased lines will in all likelihood be passed again.

It is claimed by Brooklyn Rapid Transit officials that since last fall the net revenue of the road has increased from 19 cents to 26 cents per car per mile.

The annual meeting of the stockholders of the Nassau Electric Railroad Company will be held in Brooklyn on April 12 to elect nine directors for the ensuing year.

The reorganization committee of the Lake Street Elevated Railroad Company of Chicago has agreed to extend the time for payment of the assessment until April 20.

A conference of the Inter-State Independent Telephone Association has been held in Chicago for the purpose of organizing a telephone supply company with a capital of $1,500,000.

An expert is looking over the property of the Syracuse (N. Y.) Rapid Transit Railway and the Syracuse Lighting Company, which may be sold to a syndicate including J. & W. Seligman & Co., P. A. B. Widener and others.

The Baker City (Ore.) Wonder Electric Railway & Improvement Company has filed a mortgage to secure $5,000,000 six per cent. 15-year bonds, covering a proposed 80-mile railroad from Baker City to Prairie City and 60 mining claims.

The Philadelphia Company has laid claim to the charters for Pittsburg street railway lines secured a month ago by the Verner syndicate. The members of the syndicate regard them as their personal property, and a lawsuit of great importance seems inevitable.

The property of the Lincoln (Neb.) Traction Company must be sold at auction again. Judge Holmes has decided that the company's bid of $1,025,000 for its own property did not comply with the terms of the sale. The other bid for $1,500,000, made by Lincoln and foreign capitalists, was pronounced defective. The sale is for municipal taxes.

The Norfolk, Portsmouth & Newport News Company, capital $9,000,000, of which R. Lancaster Williams is president, and which includes nearly every electric line, heating and lighting concern in southeastern Virginia, is to dissolve. The merger has not paid and the properties will be operated separately.

The New Jersey Short Line Railroad Company, with $3,000,000 capital, has been incorporated to build an electric line from Milltown to Elizabeth, 15½ miles. The new corporation is controlled by the Public Service Corporation and its line is the completing link from New York to Philadelphia.

It is understood that in addition to the new issue of General Electric stock, amounting to $3,325,000, the directors propose to issue the stock remaining unissued in the treasury amounting to $1,062,600, which will make a total issue at this time of $4,387,600. The stockholders will have the right to take a new share for every ten shares of stock now held.

EDITORIAL NOTES.

Chicago Wants Municipal Ownership.

Chicago, Ill., is about to try an experiment. At a recent election its citizens voted by an overwhelming majority to acquire and operate its street railways as municipal enterprises.

Now that the die is cast some of the deeper thinkers of the Windy City have doubts as to the outcome and claim that this radical proposition was carried at the polls because a large body of the voters were ignorant and did not know what it meant.

In this the few wise ones are undoubtedly right. Municipal ownership—not of street railways but of other things—has been tried in Boston and some of our other leading cities with anything but satisfactory results.

As has invariably happened when municipal ownership has been advocated, Glasgow in Scotland is pointed to as the *great example* in this case. But because the thrifty Scot has succeeded it is no sign that municipal ownership in Chicago will prove a success. In fact a few years ago Mr. Robert Crawford of Glasgow, a strong advocate of municipal ownership in that city, visited Chicago and in that very locality made the following remarks:

"Before I came to this country I saw no reason why American cities should not adopt municipal ownership of waterworks, traction lines and other large semi-public concerns, and wondered why they had not done so. But now that I have obtained an insight into the conditions that prevail in your cities I have entirely changed my views. As things are now in your cities municipal ownership is an impossibility. Success in that great undertaking is out of the question so long as party politics figures in municipal elections, and so long as city offices are used to reward political work. This is no derogation of the principle of municipal ownership, for that has been tried with amazing success in Glasgow. There, however, the city government has long been conducted solely for the good of the city, and I do not hesitate to make the statement that during a long term of years no public servant in Glasgow has derived directly or indirectly a single penny of profit improperly from the conduct of the city's affairs. Nor has any place under the city government been given to reward a friend of any official.

"With the conditions that exist in American cities to-day, municipal ownership is utterly impracticable. It can never be a success until the system of political rewards is entirely divorced from city government—a condition of affairs which is not claimed to exist, so far as I can learn, in any large American city at the present time. Unless the municipal government is conducted with an eye single to the welfare of the city, and unless the city officials are prompted by the same unselfish patriotism that impels a man to volunteer in time of war, municipal ownership is bound to be a disastrous failure."

This may not prove agreeable reading to city officials in general, but it indicates that the Scottish gentleman from Glasgow had a very fair insight into the methods of "playing politics" in vogue in many of our cities.

The reason given for the advocacy of municipal ownership of street railways in Chicago is that the service afforded by the local companies was poor. This may very probably be the case, but it would seem as though suitable measures might have been taken by the city officials to force the railway companies to better their service without having to have recourse to municipal ownership.

Apparently the only redeeming feature

of the whole proceeding, so far as Chicago is concerned, is the fact that the will of the people cannot be carried out until the debt incurring privileges of the city are enlarged by the Illinois Legislature.

The Incandescent Lamp Situation. In the future there will be no more shaving of prices on incandescent lamps, if the General Electric Company has its way.

At a recent meeting in this city of incandescent lamp manufacturers the Edison Electric Light Company and the General Electric Company agreed to discontinue some thirty infringement suits which had been instituted against various manufacturers, dealers and consumers, and the majority of the incandescent lamp manufacturers in the country agreed on their part to pay to the Edison Electric Light Company and the General Electric Company a royalty on every lamp sold. The two companies owning the patents style themselves the licensors, while the other companies, of which there are about twenty-six, are known as the licensees, and the whole arrangement is not a combination or trust—so the parties interested state—but is a friendly working agreement to prevent expensive litigation and the cutting of prices on lamps.

Several lamp concerns are not parties to the arrangement, among others, that of the Sawyer-Man Electric Company.

The licensors and licensees have fixed the price of lamps to be sold to dealers and consumers, and there is to be no cutting of the prices. On the other hand, it is stated that the price of lamps will not be raised. Let us hope that this will prove to be the case, but where a number of companies have matters entirely in their own hands, as have the licensors and licensees in this lamp question, it is a temptation sooner or later to boost the price up a cent or two. A cent or two a lamp does not at first sight seem much, but where some 45,000,000 lamps a year are consumed, as at present in this country, two cents a lamp means $900,000 a year. This would prove a nice extra dividend, and is a temptation that will require considerable will power to resist.

Production of Mica in 1902. In view of the fact that mica is so extensively used in the manufacture of electrical apparatus at the present day, a report on the production of this mineral in 1902 by Dr. Joseph A. Holmes for the United States Geological Survey should prove interesting.

The total quantity of mica produced in the United States during the year 1902, was as follows: Plate mica, 373,266 pounds, valued at $83,843; scrap mica, 1,028 short tons, valued at $13,081; and mica-rough as mined, or unmanufactured, 372 short tons, valued at $21,925; making a total value of $118,849.

The increase in the production of plate mica during the last three years is due to the increasing quantity of small-sized mica disks and rectangular sheets that have been cut for electrical purposes. Some of the small clear pieces obtained in cutting up the large sheets are now split very thin, rearranged, and cemented closely together, forming large sheets called micanite, which are then cut into the shapes and sizes desired. For some purposes these sheets of micanite answer as well as the natural sheets and have the advantage of being much cheaper. In recent years, scrap mica has been manufactured into a covering for boiler tubes and steam pipes to take the place of the more expensive asbestos coverings. Waste mica not available for other purposes is used in the manufacture of wall papers and lubricants. During 1902, there was, however, a large falling off in the production of scrap mica, which in 1902 amounted to 1,150 short tons, valued at $14,606, as against 2,171 short tons, valued at $19,719 in 1901.

The tables which show the great increase in the importation of mica during 1902 are significant. This increase valued at $131,278, is larger than the total value of the product of mica in the United States during 1902. It illustrates the increasing demand for mica in this country, but also suggests the sad fact that mica can be mined in India and landed in this country at a lower price than it can be mined in some places in the United States. Canada is also a large contributor to our mica supply.

Although mica is widely distributed in the United States, actual mining has been limited during the last few years to North Carolina, New Hampshire, South Dakota, New Mexico, Idaho, Virginia, and Colorado. Some development work has also been carried on in California, Nevada, Maine, Alabama, and Georgia. In several of these States good deposits of mica are known to exist that are not now available on account of their distance from railroads or other means of transportation.

We would call the attention of electrical manufacturers and engineers to the "Proposals Invited" to be found on page 207 of this issue.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The Iowa Electrical Association, which was called to hold its annual meeting in Des Moines April 13 and 14, has postponed the gathering for one week, April 20 and 21, according to announcements sent out by Secretary W. S. Porter, of Eldora. The headquarters of the meeting will be at the Savery.

Dr. Charles Baskerville, professor of chemistry and director of the laboratory in the University of North Carolina, announced Friday night before the Chemists' Club in this city his discovery that thorium, hitherto known as one of the 70 primary elements, is complex in its nature. Dr. Baskerville has resolved thorium into two new elements. He has named one of these carolinium, after the State; the other berzelium, in honor of the great Swedish chemist who nearly a hundred years ago discovered thorium. It has never before been the good fortune of an American chemist to discover a chemical element. Dr. Baskerville's discovery of two elements is the result of ten years of persistent labor.

At a meeting of the executive committee of the International Association of Municipal Electricians, held at Brooklyn, N. Y., April 2, the following papers were selected and assigned to be read at the ninth annual convention to be held at St. Louis, September 13-14: "Street Lighting, Principles Involved and Systems Used," A. S. Hatch, Detroit, Mich.; "The Limitations of the Telephone for Fire Alarm Purposes," Adam Bosch, Newark, N. J.; "The Inspection of Theaters from an Electrical Standpoint," William H. Thompson, Richmond, Va., "Methods of Testing," Walter M. Petty, Rutherford, N. J.

The Crocker-Wheeler Company of Ampere, N. J., has arranged to insure the lives of all of its workingmen for the benefit of the men's families. The plan is practically complete, and its prime object is to further the interests of the men employed. It is planned that the Crocker-Wheeler Company, will assume the expense of the insurance and create a reserve fund to cover losses. Families of the workmen will be the beneficiaries, and the plan will be probably that known as straight life insurance. It has been suggested that a form of endowment insurance be established, and that idea is being held under advisement.

THE LIVERPOOL-SOUTHPORT ELECTRIC RAILWAY.

(From our London Correspondent.)

(Concluded from page 187)

The sub-station equipment, save as regards amount of plant, is identical, and to describe one in detail will give an adequate idea of the whole of them. The three largest, Seaforth, Sand Hills and Formby, have each four rotary converters, whilst Birkdale has three, provision being made in each case for extensions. Each rotary converter is arranged with its corresponding groups of statics alongside, the high tension oil switches being placed underground.

The rotary converters are in appearance similar, in general design, to the standard direct current machines. They are 8-pole developing 600 kw. at 600 to 650 volts at 375 revolutions per minute. The core disks are segmental and dovetailed into machined grooves on a cast-iron spider, the rim of which following standard practice is sectional to avoid shrinkage strains.

On the alternating current side of the machine are six gun-metal slip rings, which tap the armature windings at equidistant points, connection between the radials and the outer rings being effected by insulated bolts carried through the intervening rings.

Each slip ring carries three laminated copper brushes.

On the direct current side carbon brushes are used, which slide in radial brackets under the pressure of compensating spring levers. The average finished weights of this rotary are armatures 10,380 lbs, magnets 21,100 lbs., complete machines 40,940 lbs.

The transformers are of the air-blast type, and have each a capacity of 200 kw.

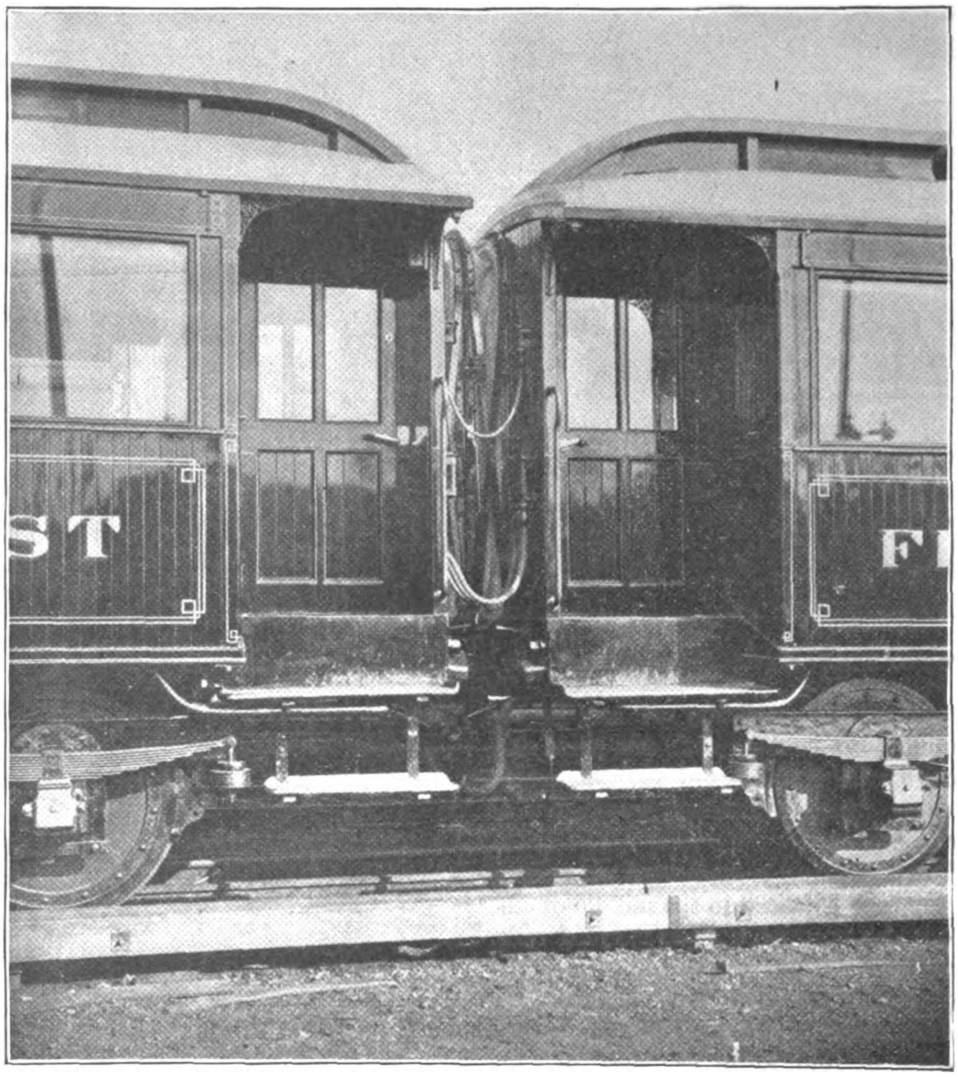
The blowers, of which there are two in each sub-station, consist of a standard Dick, Kerr 5 hp. motor, coupled on a combined base to a Davidson Sirocco fan, which is keyed direct on the motor shaft. The capacity of each fan is 8,000 cubic feet of air per minute, at a pressure of 2 inches to 3 inches of water.

The sub-station switchboads consist of a high tension and low tension side, the latter having been supplied by Elliott Bros., the switches and circuit-breakers being of the standard Dick, Kerr pattern.

The high tension cables leading from the power house are arranged in each case in triplicate. Under ordinary working conditions all three cables are used, but in case of breakdown of any one of the cables, the two remaining ones can do the work without the drop or current density exceeding the permissible limit. The cables were made by W. T. Glover & Co. The extra high tension cables are of the triple triangular type, diatrine paper insulated, lead covered and armored, laid on the solid system.

Turning now to the permanent way, two additional rails have been laid. One of these is brought alongside each track on insulators, while the other is placed between the running rails, uninsulated on shoe is provided on the train for this fourth rail, the current being delivered through the wheels to the running rails, and thence through the cross-bonds to the fourth rail. The third and fourth rails are both of equal section, mild steel, 70 lbs. per yard, and laid in 60 foot lengths.

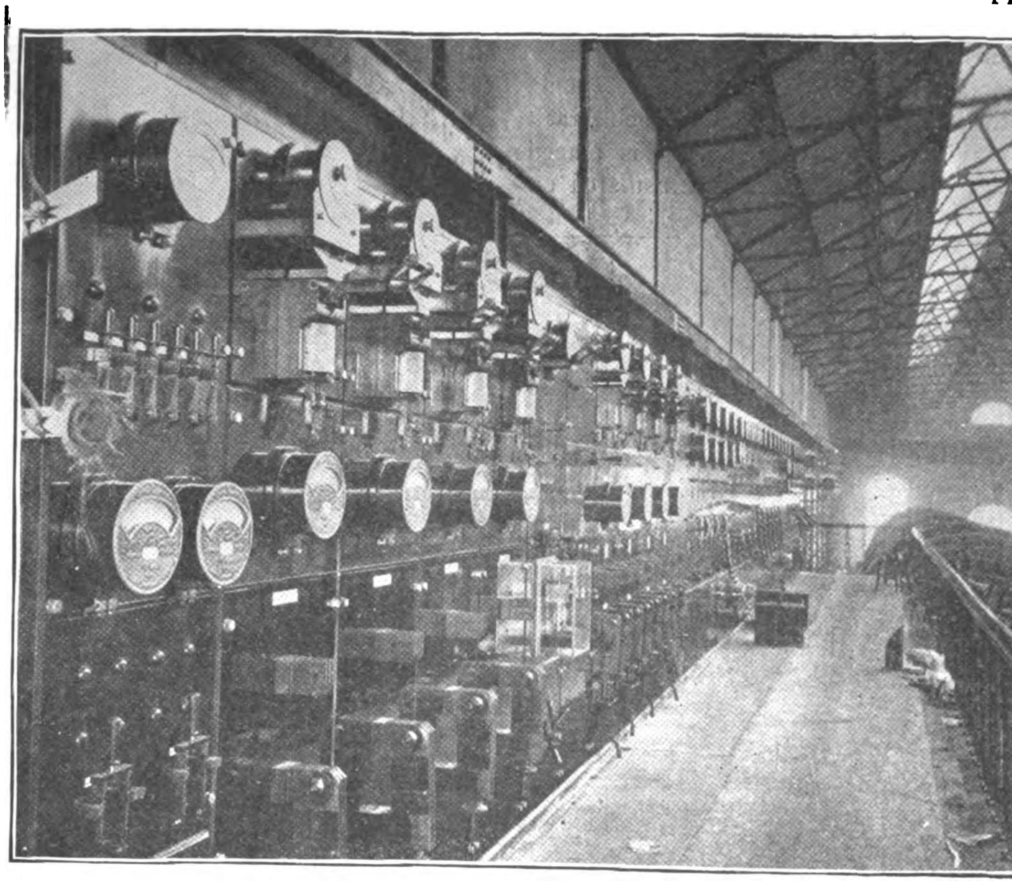
The third rail is supported at intervals of about 10 feet on insulators of reconstructed granite, held in position by two



Cars Coupled on the Liverpool-Southport Electric Railway.

the sleepers, this forming the principal part of the return circuit, while the joints of both the third and fourth rails are bonded in the ordinary way; the fourth rail is also cross bonded to the running rails, the ends of each running rail being connected by such a bond to the fourth rail. While by this arrangement the troublesome bonding of the running rails is avoided, as also the complications involved by using an insulated fourth rail for the return, the further advantage is obtained that the running rails participate to a marked degree in conducting the return current, thus increasing the conductivity of the return circuit, with consequent reduction of drop. No collector clips, the center of the rail being exactly 3 feet 11½ inches from the center line of the track, and the top of the rail 3 inches above the surface of the track rails. This dimension being that agreed upon by all the main line railway companies in order to obtain uniformity, in case of extensions of third rail system. It is of ample section to convey the full amount of current required by the trains, when between two sub-stations, without causing any appreciable loss in voltage. Generally the third rail is placed in the 6-foot way between the tracks, but occasionally it is brought outside the track, to suit special conditions. At all level crossings gaps in this rail have been provided of such a

length that there can be no risk whatever to the public; where these gaps occur the third rails are bonded with cable underground. Timber guarding has been provided at all the busy places on the line,



Power Station Switchboard on the Liverpool-Southport Electric Railway.

to prevent the possibility of any person coming into contact with the third rail, though even if they did so, the consequences, while unpleasant, would not be serious.

The fourth rail is supported on wooden blocks, and is placed in the middle of the 4-foot way between the two running rails.

At most stations the third rail is interrupted and the ends are connected by cables to section switches. This apparatus consists of four knife switches, one for each end of the up and down line, which, in the ordinary way of working, are connected in parallel. By cutting out one of these switches in two adjacent boxes, any part of the up or down line may be made currentless.

In providing for expansion and contraction, due to change of temperatures in the rails, they are divided into sections of 300 feet, and the joints between the rails making up this section are known as "fixed joints." The joints connecting the sections themselves are known as "expansion joints." At the fixed joints no provision is made for expansion or contraction, this being concentrated at the expansion joints. The fish plates at the fixed joints are made as rigid as possible, and the bonds are four in number, two bonds being fixed in the web of the rail, and two bonds in the flange of the rail.

It was deemed advisable to use bonds of semi-flexible type, which have a conductor built up of parallel strands of copper ribbon or "flat wire" with solid copper terminals. They are thus sufficiently flexible to provide for any movement which may take place at the joints, and are more easily adjusted in case of any variation in distance between the bond holes at the time of construction. The bonds at the expansion joints are four in number of the same cross section as those at the fixed joints, but all four are fixed in the flange of the rail. These bonds are also made of "flat wire."

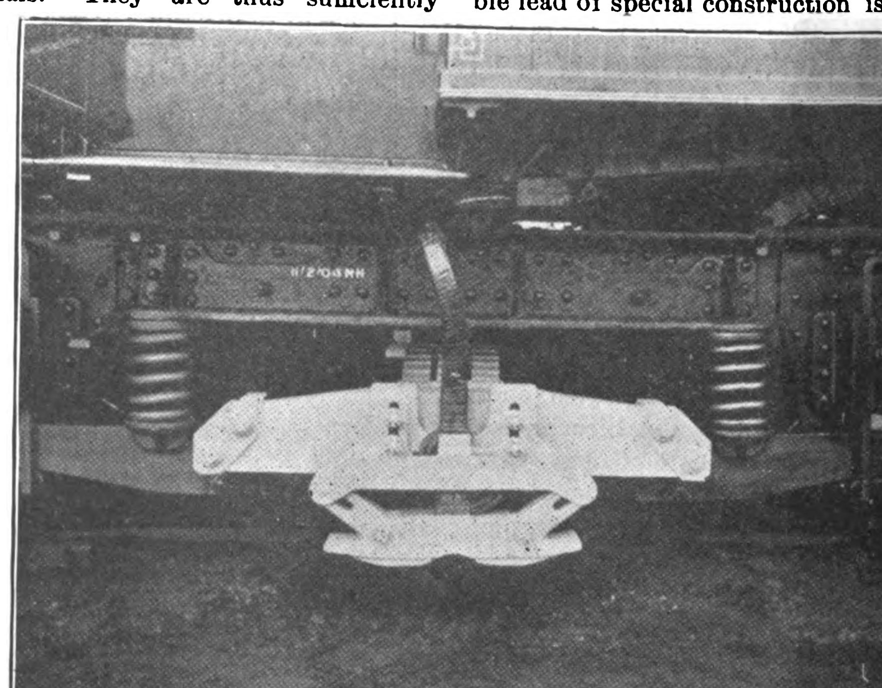
The fish plates at the expansion joints are of special design, and properly slotted to provide for any change of length which may take place in the 300 feet section. This system of bonding is carried out on both the third and fourth rails. The terminals of all the bonds are of solid copper and are expanded in the bond holes by means of screw or hydraulic compressors.

Each track rail is bonded to the fourth or negative rail by means of flexible cable bonds. The bonds were supplied by the Forest City Electric Company.

The trains consist of two first and two third-class cars as a rule. The thirds are at either end and are equipped with two motor bogies, each bogie carrying two Dick, Kerr 150 hp. motors, there being eight motors per train. A cast-steel slipper attached to a beam on each side of the motor bogie, rubs on the third rail.

The motor bogies are built entirely of steel and have 8 feet wheel base. The wheels are an exceptional size in electric traction, being 3 feet 6 inches.

The slippers weigh about 90 lbs. each. On straight runs there are four shoes collecting at one time. From these slippers, which are suspended by forged slotted links from a wooden beam carried on extensions on the bogie, a highly flexible lead of special construction is carried



Brake on the Liverpool-Southport Electric Railway.

to a fixed terminal from which the main cables pass to the controller.

A large motor car horn containing a reversed reed of special construction is used in place of a whistle, a connection to the vacuum reservoirs enabling the air

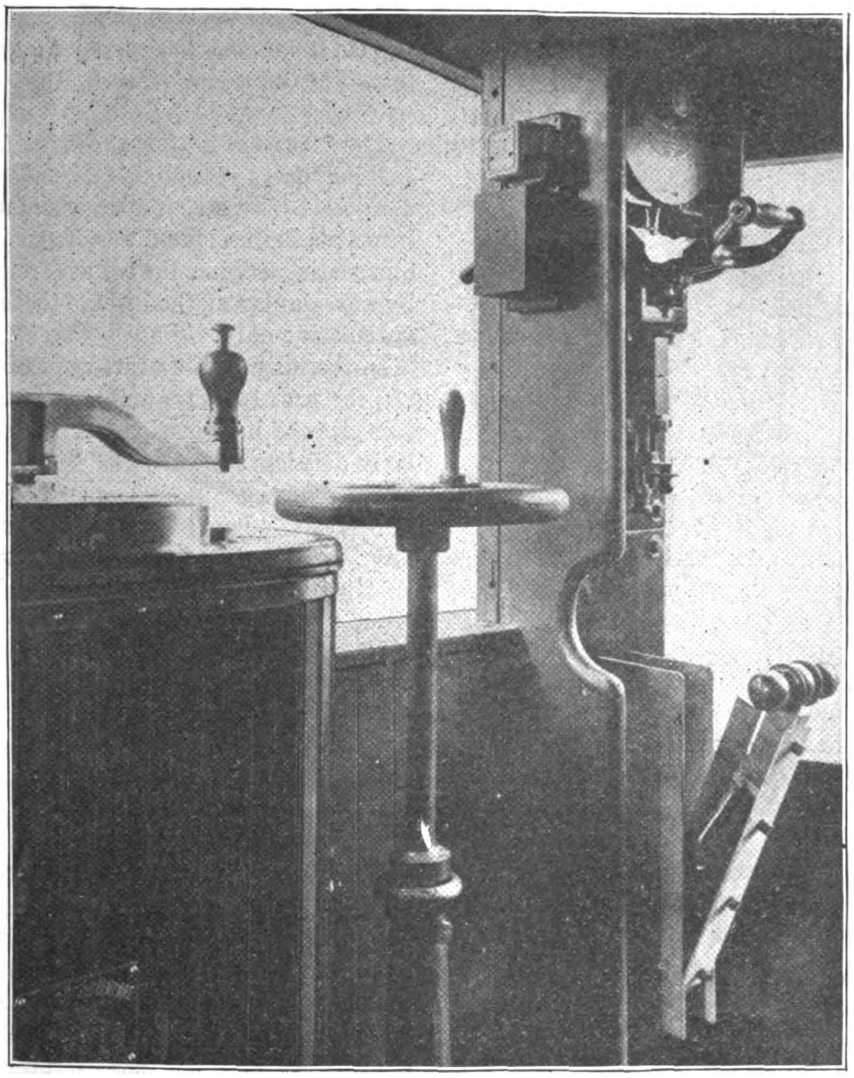
for blowing it to be supplied from the atmosphere.

The motorman's compartment, in addition to the controller and switches for the main motors, contains a motorman's brake valve, a vacuum gauge, a single pole switch for starting the brake motors and fuses for the pump motor and brake control circuits.

The motor compartments have, with the exception of the roof, which is covered with sheet steel plates, been lined with uralite, a fireproof material, the floor also being fireproof. In addition to the cable troughs, in which the cables are placed for conveying current to the motors and equipment, being lined with uralite, the whole of the floor over the motors is covered with the same material and thin steel plates. All the trains carry fire appliances, and ample steps have been taken to insure safety in this respect.

The motors are of the Dick, Kerr 4 A railway type and they drive on to the axles through single reduction gear. They are rated to develop 150 hp. at an armature speed of 470 revolutions. The complete motor weighs 6,050 lbs.

One of the most interesting features of the equipment is the method of control, which is known as the direct multiple control system, in contradistinction to the multiple unit, the main difference in the systems being that in the case of the former it is possible to control the whole equipment of the train by means of two main cables. Previously, the great difficulty in the way of such a simple arrangement lay in the construction of the controller, it being practically impossible to carry the whole of the current through one controller. In the Dick, Kerr system this is rendered possible by the use on the controller of the metallic shield blow-out, which is part of the standard design of their tramway and railway controllers. They contain two power cylinders, each controlling one-half of the train, that is, one motor car is actuated from one cylinder and the rear motor car controlled from the other. Without, therefore, interfering in any degree with the completeness of the train, it would be possible to divide one of the present trains into two distinct units. In other words, the system is claimed to embrace the whole of the advantages of the multiple unit control without the necessity of employing numerous connections involved by a contractor system.



Interior of Cab (right side) on the Liverpool-Southport Electric Railway.

The train is entirely operated by the motorman in his cab at the front.

In the cab is a Dick, Kerr D. M. 4 controller capable, in conjunction with eight reversers, which are bolted up adjacent to their various motors under the floor, of operating the eight motors on the pair of motor cars.

The two power cylinders of the controller are geared together and operated from a crank handle, each cylinder barrel being flanked by a powerful metallic shield blow-out solenoid. These may be swung open on hinge pins, such action automatically cutting the winding out of circuit, or, if necessary, lifted off and removed for inspecting the cylinders and contact fingers.

There is also provided two sets of a single-pole quick-break knife switches, and metallic shield blow-out circuit breakers, each of these designed for an overload with a calibration of 500 to 1,600 amperes.

The reversal of direction of the motors is effected by means of a special apparatus operated by the controller reversing barrel. This reversing apparatus carries contacts which are normally left open by gravity, but can be closed by an electromagnet, which becomes operative through the agency of the controller reversing barrel. There are eight reversers per train, one per motor, which are arranged in four parallels of two in series across the system. In series with each reverser pair are the contacts of two magnetic overload releases, the coils of which are each in the main circuit of one of the motors, its reverser contacts and solenoids. Consequently, whether a pair of motors be in series or in parallel, the overload current in either one will cause both releases to open and cut out the pair. These releases are inclosed in small neat cast-iron boxes mounted on the sides of the car near the truck facing outwards. When open, a flap falls down exhibiting "open" in raised white letters on a scarlet ground, which catches the eye immediately. The releases may also be tripped by hand to cut out any pair of motors that may become disabled.

Powerful and certain action of the reversers is secured by a compact magnetic circuit and a free and balanced suspension of a heavy clapper, while uniform and reliable contact is insured by the use of several independent spring contacts, so hung as to render sticking impossible.

In circuit with each pair of reversers is

a cartridge fuse and hand knock-out switch in the cab. The latter is for opening the relay circuits of the reversers, in order to cut off the motors should the controller cylinders stick in any way, or an accident be imminent.

In accordance with the usual practice, the power cylinder is locked when the reversing is in an "off" position, and only then can the handle be removed, while the reversing is locked when on "reversed" or "ahead" and the power on one of the notches.

The power couplings between two cars simply consist of stationary male plug contacts in insulating tubes screwed to the ends of the coaches, with dummies facing them on the coaches opposite, into which female plugs, buried in insulating handles at the end of long flexible leads, click home, according to whether connection or disconnection is required.

The heat, light and reverser couplings are mechanically in one and similar in arrangement to the power.

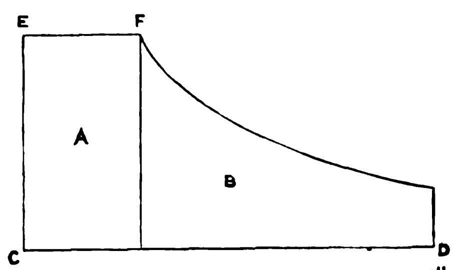
They are all mounted about half-way up the car wall comfortably in reach from the platform, thus obviating all risk of getting on the track and shocks from the third rail.

INDICATOR DIAGRAMS FROM STEAM TURBINES.*

BY W. H. BOOTH.

It is so often stated that the steam turbine cannot be indicated that there is a tendency to accept such statement as true. It is by no means true, but has been made by those whose ideas of indication are drawn from the instrument employed by the reciprocating engine. The steam turbine can be "indicated" with a very considerable degree of precision, and though the writer in not prepared to suggest at the moment an autographic recorder of the "indication," there is very little doubt that such a record could be contrived. An indicator diagram, as usually obtained from the reciprocating steam engine, is a record of the steam pressure at every point of the piston stroke. It is employed as a means of finding the power exerted on the piston. It does not directly tell us the power exerted by the working steam. The power exerted in a steam engine is made up of two parts. First, during the admission of the steam into the cylinder, the heat of the fire under the boiler is directly converted into work, a certain portion of the steam being pushed into the cylinder by the direct action of fire causing evaporation in the boiler. If the steam pipes are small, the full boiler pressure may not be carried through to the cylinder, and during the steam admission period the steam which is pushed out of the boiler by the direct furnace heat may act partially by expansion, and do some work during admission. Admitting a level admission line, however, the initial steam does no work by expansion. When the admission valve closes, the inclosed steam expands behind the piston, and does work. In the diagram, Fig. 1, the two portions of work are shown by the areas A and B. A is the work done directly by the furnace, and B represents that done by the expanding steam. The line C D is the line of absolute vacuum. The gross work done is represented by the area D C E F. On the opposite side of the piston, however, there is work done by the atmosphere, or by

Fig. 1.



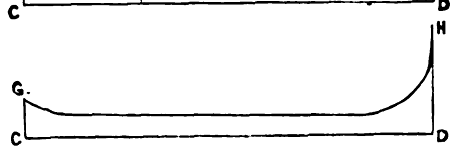


Fig. 2.

the steam in the exhaust pipes and condenser, and this is shown by the diagram Fig. 2, the work done being represented by the area D C G H. The actual indicator diagram as secured from an indicator does not show the two diagrams which represent one stroke upon the same card, but shows the condition of things on one face of the piston only during two strokes. The actual so-called indicated power of an engine is the difference between the gross forward pressure of all the cards for Fig. 1, and the gross backward work of all the cards for Fig. 2. The best of two engines may be made to appear the worst if care be not taken to keep to a minimum all the Fig. 2 cards.

Such cards as this cannot be gotten from the steam turbine, but, nevertheless, the pressure in the turbine can be gotten at any part of the length, and from this something can be learned of the behavior of steam in the turbine, and particularly of the effects of superheated steam. Where saturated steam is employed in the turbine, its temperature at any point can be ascertained by means of a mercury pocket of thin brass let into the body of the outer casing. A series of these pockets fitted along the length of the turbine, and fitted with thermometers, will give a series of temperature readings at such points which can be plotted as a curve of pressures by aid of a steam table, or the thermometers may be graduated in pounds to avoid translation. A series of pressure gauges may also be used, and will correspond with the thermometer readings at the same section. The rate of expansion can be found in this manner as an aid in fixing upon the dimensions and proportions of the several parts. Where superheated steam is employed the difference of the readings of the pressure gauges and of the thermometers will show the extent to which the superheat is retained as the steam travels through the turbine.

The constancy of the conditions in a turbine on a steady load renders such methods of investigation easy and reliable, in which the turbine differs from the reciprocating engine, the results from which by any similar method would be at least speculative only.

In the flood of literature appearing during the past 10 years on steam turbines, this class of information has been singularly deficient.

Tests giving steam consumption per kilowatt hour may induce purchasers to buy turbines, but they are comparatively as valueless as the photographs of high-speed boats for any information they afford on the principles underlying the turbine, and the action in it of the working fluid.

The B.H.P. for a turbine is so easily gotten that the I.H.P. as obtained from the reciprocating engine may be dispensed with. The chief value of an ordinary indicator diagram is to show the action of the steam in the cylinder, and it is the action of the steam, especially in the long variety of the turbine, that is now of more serious interest. As already surmised, the effect of superheat is probably obtained at an earlier temperature than is necessary in reciprocating engines, but better assurance of this would be gained by a series of positive records of temperatures and pressures taken in the course of the length of a turbine. There are many who think that turbines have grown too long, and that the larger ends are mere churns; that the claims for extended expansion are somewhat overdrawn and that more modest dimensions would serve. Such questions would be better answered were information forthcoming in the direction indicated. With the growing number of makers it is hardly likely longer be to neglected.

*From the "Electrical Review," London.

If already obtained and not published, it may account to some extent for the slow progress made by this most interesting of steam motors.

ELECTRICAL STATION PRACTICE.

ARTICLE XXXII.

BY W. H. RADCLIFFE.

The amount of electrical power provided by a generator, its percentage of efficiency, and the values of the various losses occurring in its operation are matters that must be determined from time to time in the management of an electrical station. The determination of these values in the ordinary case of a direct current generator will be considered in the present article.

The power which is furnished by a generator for use in the main circuit is that generally implied when the term "electrical power" or "output" is mentioned. This quantity is measured in watts or in kilowatts according to its size; if the output is less than 1,000 watts it is expressed in watts, otherwise it is expressed in kilowatts, 1 kilowatt being equal to 1,000 watts, and 1 watt being equal to 1 volt multiplied by 1 ampere. In order therefore to obtain the value of the output of a generator it is merely necessary to measure its pressure on a voltmeter, its corresponding current in the main circuit on an ammeter, and multiply together the values thus found. The total electrical power developed by a generator is some value greater than this, being in addition to that supplied to the main external circuit, the power used in the armature and field windings. The value of the total electrical power does not, however, enter into the output of the generator, as this term is commonly interpreted, but in the design and construction of a machine it must necessarily be considered.

The efficiency of a generator in its commercial sense is the ratio of the electrical power supplied by a generator for use in the main circuit to the mechanical power which must necessarily be used to produce it; in other words, it is the output of the generator divided by the input of the generator, both these quantities being expressed in the same terms. The commercial efficiency is expressed as a percentage of 100, 100 per cent. representing the efficiency of an ideal generator converting the entire mechanical power applied to its shaft into useful electrical power in the main circuit. In practice only about 90 per cent. of the mechanical power is converted into useful electrical power, the remaining 10 per cent. being used in overcoming the losses, which will later be considered.

There is in addition to commercial efficiency another term, "electrical efficiency," which must not be confounded with it. The electrical efficiency is the ratio of the electrical power supplied to the main external circuit to the total electrical power developed in the generator; obviously, its value is governed entirely by the internal resistance of the machine, that is, the resistances of the armature and field windings. In modern generators the internal resistance is generally such as to cause a loss of about 4 per cent.; the average electrical efficiency of a generator is therefore approximately 96 per cent. As both the total electrical power and the electrical efficiency of a generator are matters that can be calculated directly from the losses, that will later be discussed, we will turn our attention now to the testing of a generator for obtaining its commercial efficiency.

The commercial efficiency of a machine is usually taken at different loads so that an efficiency curve may be drawn. To illustrate the method employed, however, it will merely be necessary to find its value at one point, and for this purpose let the full load point be selected. The problem then resolves itself into finding the mechanical input at full load, and the electrical output at full load. In order to determine the former of these values it will generally be found advisable to run the generator as a motor at its rated speed, and to load it by means of a Prony brake. The generator must be stripped of all belting or other mechanical connections, supplied with its normal voltage and full load current, and the pressure of the Prony brake upon its armature shaft or pulley adjusted until the rated speed of the armature is obtained. The number of foot-pounds developed by the armature and measured on the Prony brake under these conditions should be substituted for T in the formula

$$P = \frac{T\,(2 \times 3.1416 \times S).}{33{,}000}$$

In this formula P represents the number of horse power that must be applied to the machine in order to cause it to develop its rated full load at normal speed, T denotes the value in foot-pounds determined by the Prony brake, and S represents the speed of the armature in revolutions per minute. The substitution of these respective values in the formula just given, and the solving of the right-hand side of the equation will give the value in horse power of the mechanical input at full load. The electrical output in horse power at full load is easily calculated by multiplying the normal voltage by the full load current and dividing by 746. Now, since we have both the input and the output at full load expressed in horse power, dividing the former value by the latter will give the percentage of commercial efficiency of the generator at full load.

A simpler method of obtaining the commercial efficiency of a generator, if there be available an electric motor for which there has been drawn a calibration curve giving the various horse powers developed when this motor is supplied with a given number of volts and amperes, consists in running the generator with this motor and measuring the number of watts generated for the corresponding power applied. By simply converting these two quantities into the same units, and dividing the former by the latter, will give the percentage of efficiency of the generator.

Having ascertained the commercial efficiency, or briefly the efficiency of the generator, by either of the methods previously described, the difference between the ideal 100 per cent. and the efficiency found will be due to certain losses in the generator about to be discussed. These losses may be classified as mechanical losses and electrical losses; of the former are the friction of the belt, the friction of the brushes, and the resistance or friction of the air; of the latter are the eddy current loss, the hysteresis loss, the armature resistance loss, and the field resistance loss. The usual methods employed for determining these various losses in the order named will now be taken up.

First of all, the generator to be thus tested should be belted to a calibrated motor which latter machine should preferably be of the constant potential, shunt wound type. By the term "calibrated motor" is meant one for which a calibration curve has been drawn, as described in the second preceding paragraph. The friction of the bearings and belt of the generator are determined together by raising the brushes off its commutator and running it at the rated speed by means of the calibrated motor. The amount of power as ascertained from the calibration curve of the motor for the voltage and current used therein when driving the generator, as just explained, is a measure of these two losses. The power thus used is practically constant at all loads and is about 2 per cent. of that necessary to drive the generator at full load. The friction of the brushes can very conveniently be determined next by simply

lowering them on the commutator and giving them the proper tension. The increase of power resulting from the greater current that will now be taken by the motor to run the generator at the rated speed, will be a measure of this loss. In general, its value will be about .5 per cent of the total power required to drive the generator at full load, and this also will remain constant at all loads. The friction of the air upon the moving armature of the generator cannot be determined experimentally, but theoretically this loss is small and may be estimated as .5 per cent.; it is also constant at all loads.

Coming now to the electrical losses, the eddy current loss and the hysteresis loss are next in order. In practice, these two losses are generally combined and called the core loss of the generator. As such, it may be determined experimentally by exciting the field magnets of the generator with the normal full load field current through the magnet coils, and noting the increase of power required by the motor to maintain the rated speed of the generator thus excited under no load. The value of the core loss is approximately 3 per cent. of the power required to operate the generator at full load, and it is constant at varying loads. If it be desired to divide the core loss into its component parts, it is necessary to also run the generator under the same conditions as before but at half its rated speed. If, then,

h = the power lost in hysteresis at rated speed,

e = the power lost in eddy currents at rated speed,

t = the power lost in hysteresis and eddy currents at rated speed,

s = the power lost in hysteresis and eddy currents at half speed,

there may be formed the two following equations:

$$t = h + e, \text{ and } s = \frac{h}{2} + \frac{e}{2},$$

from which the elimination of h will give $e = 2t - 4s$. By referring to the notation previously given the letters in the last equation, the interpretation thereof is that the power lost in eddy currents at rated speed is equal to twice the power lost in hysteresis and eddy currents (core loss) at rated speed minus four times the power lost in hysteresis and eddy currents at half speed. The value of the eddy current loss thus found will be about 1.5 per cent. and constant at all loads.

Having previously ascertained the power lost in both eddy currents and hysteresis, and knowing now the power lost in eddy currents alone, it is easy to find that lost in hysteresis by simply subtracting the latter known value from the former. The value of the hysteresis loss is therefore approximately 1.5 per cent., and it is constant at different loads.

There yet remains to be determined the armature resistance loss and the field resistance loss, but as for the calibrated motor this may be disconnected from the generator as it need not be used further in the test. The armature resistance loss necessitates that the resistance of the armature winding between the commutator bars upon which press the positive and negative brushes, be measured. The method of measuring this resistance will be described in the next article, wherein will also be taken up other measurements that are at times required in electrical station practice. Let us assume, therefore, for the present, that the value of the armature resistance be known. This value, which we will call R ohms, together with that of the full load armature current, which is also known and which we will call C amperes, are sufficient data for calculating the armature resistance loss at full load. It is evident that to force the full load current C through the armature resistance R will require a pressure of CR volts, and that the watts lost in doing so will be the voltage multiplied by the current or $CR \times C = C^2R$ watts. Expressed in horse power, this loss will be $\frac{C^2R}{746}$, and at full load it usually will be about 2 per cent. of the total power required to drive the generator fully loaded. The armature resistance loss varies in proportion to the load, in fact, as the last expression shows, it increases as the square of the armature current.

The field resistance loss is calculated in precisely the same manner as just explained for the armature resistance loss, it being equal in horse power to the square of the full load field current multiplied by the resistance of the field winding and divided by 746. In a shunt generator it is practically constant at 2 per cent. of the total power applied at full load, but in a series or in a compound generator it will vary in proportion to the load.

The electric system that was recently installed in the Lehigh Valley Coal Company's Centralia, Pa., colliery has proven so satisfactory that the question of installing it at other collieries is now being considered, and it is also proposed to make it the motive power for pumping machinery, a new innovation recently introduced with success at the Enterprise colliery.

STANDARD PRACTICE IN THE USE OF ALTERNATING CURRENT ELECTRICAL APPARATUS.*

BY J. J. GIBSON.

(*Concluded from page 192.*)

Were the speed of the engines practically constant at all loads, the distribution between the loads of the engines would be indeterminate. Where the speed characteristics are identical the load is evenly divided if we have units of same size and equal armature reactions.

Were the speed characteristics not straight lines and were they to fall off more rapidly at the higher loads than at the lighter loads, then there would be more even distribution at the higher loads than at the lighter for the reason that the horizontal distance between the speed characteristics is less the more rapidly the curves fall off to the horizontal.

Engine manufacturers thoroughly appreciate this situation. They recognize all of these requirements, and they are meeting them.

The steam turbine affords absolutely uniform angular velocity. The water wheel does also. In the case of the water when the momentum of the column of water has a similar effect to that of a flywheel and may cause the water wheel governor to continue to act after the time when it should stop acting.

While the problem of properly driving alternators in parallel is a mechanical problem, still, there are conditions in an electrical circuit which give rise to chances of hunting or surging of the load. If a load on a system is entirely uniform, or what you may call a dead load, then such chances are not present. If, however, the generators are serving a load made of synchronous motors or rotary converters, which we might call a synchronous load, the load is a pulsating one and we have a condition where a prime mover delivering its power by impulses is feeding a pulsating load. There is a reaction back on the generator from the load because the power is taken intermittently and this reaction may cause the generator to vary in its angular position. This action is prevented by placing what are known as dampers on field poles of synchronous motors, rotary converters and on the generators themselves. These dampers consist of copper grids set into pole faces, which are in reality nothing but paths of low resistance in which currents flow, which are induced by any tendency of the magnetic

*Paper read at the twelfth annual convention of the Northwestern Electrical Association, held at Milwaukee, Wis., Jan. 20-22, 1904.

flux through any pole to change in intensity or position. Electric dampers are nothing but electrical dash pots. Referring to Fig. 1, previously discussed, if the load is a synchronous load in which the synchronous machinery is furnished with dampers, we can find a mechanical analogy in Fig. 2 by seeing that the shaft is equipped with a dash pot, which resists sudden angular flexure.

With all the past difficulties, and it might be said that they are practically overcome, parallel operation of alternating current generators may be said to be standard practice except in cases where extreme nicety of regulation on lighting circuits is essential. In such cases generators in the station carrying such loads are separated from generators carrying power factor loads, but this separation is more on account of regulation than on account of any difficulties from surging of load arising from parallel operation.

The operation of connecting in parallel alternating current generators requires that the machines shall be in phase, at the same frequency, and also giving the same voltage. If thrown together under other conditions large currents will flow between the machines. A slight phase difference does not matter so much as the machines will pull each other into step, but at the cost of large cross currents. A slight voltage difference is also not a very serious matter.

In order to determine whether machines are in synchronism, the common method is to use lamps connected as in Fig. 4, which illustrates the principal of this method. A and B represent two single-phase generators, the leads of which are connected at a switch, through two series of incandescent lamps, D and E. It is evident that as the relative positions of the phases of the EMF.'s change from that of exact coincidence to that of exact opposition the flow of current through the lamps varies from a minimum to a maximum. If the EMF.'s of the two machines are exactly equal and in phase the current through the lamps will be zero, and as the difference in phase increases, the lamps will light up and will increase in brilliancy until the maximum is reached, when the phases are in exact opposition. From this condition they will decrease in brilliancy until completely dark, indicating that the machines are again in phase. The rate of pulsation of the lamps depends upon the difference in frequency, i. e., in the speeds of the machines, and by adjustment of the governor of the engine or water-wheel, or the tension of the belt, the rate can generally be reduced to as low as one pulsation in ten seconds, which affords ample time for throwing the switch connecting the generators in multiple.

Fig. 4 shows connections for paralleling low-voltage single-phase generators. For high-voltage single-phase generators con-

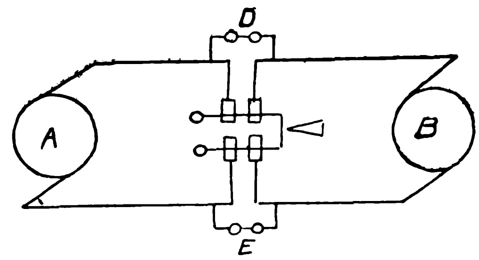

FIG. 4.

nections are as shown in Fig. 5. For synchronizing polyphase generators, the method is practically the same, when lamps are used, one phase of one machine being synchronized with the same phase of the other machine.

Although lamps are quite generally used for synchronizing, still the most satisfactory method is to use a synchroscope. A synchroscope is an instrument designed for this purpose and has the advantage of the lamp method because it shows the slightest difference in phase or frequency, whereas lamps do not. Since the ordinary incandescent lamp will not glow unless 40 per cent. or more of its rated voltage is applied, the dark period of the lamps when being used in synchronizing is quite long. The operator has to interpolate a succession of lamp brightness when using lamps for synchronizing, and if he throws the machine together at the wrong period of the dark interval, he may do so when there is a considerable difference in phase between the respective circuits.

The synchroscope indicates whether the incoming machine is running too slow or too fast; it indicates also the amount

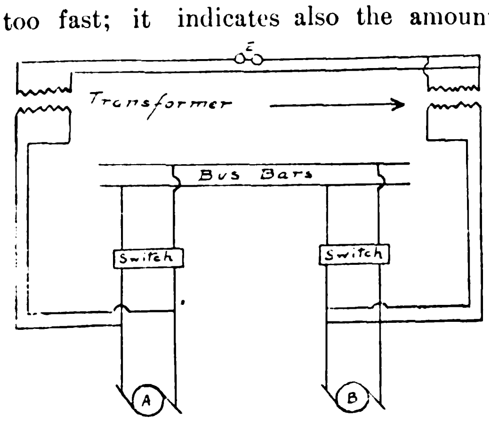

FIG. 5.

by which it is too slow or too fast, and it indicates the exact instant of synchronism.

The characteristics of the winding of an a. c. generator depend on the nature of its load. Characteristics of systems of distribution depend also upon the load which they supply. Practice has about settled into these lines.

As to frequency: For lighting only, 60 cycles per second, 7,200 alternations per minute; for lighting and power, 60 cycles; for power alone, 25 cycles, 3 alternations per minute; for incandescent lighting alone we may expect to find for some time to come high frequency plants, such as 133 cycles, 16,000 alternations, although these are rapidly passing away due to the fact that arc lights can not be operated at that high frequency with unqualified success, and due also to the fact that high frequency is not suitable for power work. It does, however, permit of transformers being built with less weight for the same core loss than lower frequencies. Then, too, a high frequency machine is not adapted for direct connection to engines of low speed, for example, a 16,000 alternation machine would require 160 poles if run at Corliss speed of 100 r.p.m. This would be a monstrosity.

One hundred and thirty-three cycles, 125 cycles, and other high frequencies were first used in central stations which carried only an incandescent load on a single-phase system, using high speed, belted generators and cheap air cooled transformers. As before stated plants of this character are rapidly passing away. Central stations nowadays look for a motor load so that they may run during the daytime, and the alternating current series inclosed arc system is being installed everywhere, so that what the central station man wants now is a generator which is suitable for supplying current for any class of service he has, arcs, incandescents or motors. This he can find in the 60 cycle generator, for this frequency is not too high for power either in motors or rotary converters, and it is about the lowest allowable frequency for successful operation of arcs and incandescents. Incandescent lights on lower frequencies show a fluctuation in light intensity, which, if not exactly visible, is nevertheless felt by the eye. An arc lamp to work on 25 cycles or thereabouts has not yet been perfected. The lower frequencies, such as 25 cycles, greatly shorten the life of Nernst lamps. There have been polyphase incandescents brought out in which there was a film in each phase, thus overcoming the light fluctuation by virtue of "heat inertia." No great success, however, has attended the exploitation of such wares.

For a pure and simple power proposition, 25 cycles has come to be standard. It gives low speeds for motors, and al-

though rotaries are successfully built and operated on 60 cycle systems, still the design of the 25 cycle rotary is less difficult and expensive. In generators, synchronous motors, rotary converters, low frequency means fewer poles for the same speed, consequently cheaper construction. All this tends toward simplicity. On the other hand, however, low frequency means larger and more simply designed static transformers in order to keep core losses down.

It is possible that future developments in traction work may call for a lower frequency than 25 cycles. The Washington, Baltimore & Annapolis road, using single phase motors on its cars, will have a system operating at 2,000 alternations, 16⅔ per second, but a line of single-phase street car motors for 25 cycles is now on the market. Frequencies such as 40 and 50 cycles have been exploited and abandoned. There is quite a good deal of 30 cycle apparatus and some 26⅔ cycle. Everything considered, however, 25 and 60 cycles have won out in their respective fields so far.

As to the choice of number of phases: All lighting work is single phase, whether circuits be taken from single or polyphase generators. Stations carrying an incandescent lighting load with no prospect of ever having a power load should use single phase apparatus. As long as there are such stations, we may expect to find standard lines of single phase generators. As single phase distribution is not suitable for the operation of motors it is necessary in a station carrying a mixed load to use polyphase generators, which supply different systems of feeders, polyphase feeders for power circuits and single phase feeders for lighting circuits. The balancing of the load on the different phases of such a machine is a question of some moment. It is therefore a problem to be considered in each installation whether or not two or three-phase shall be used. Three-phase distribution for power calls for about three-quarters of the copper which would be used in two phase distribution. On the other hand it is easier on a lighting load to keep two phases balanced than it it is to keep three phases balanced, and the lowering transformer equipment is more expensive in three-phase distribution. For a station, therefore operating a mixed load where the lighting load predominates, two-phase is far better than three-phase. When the power load increases to a point where 25 per cent. of the copper in that branch of the service becomes a considerable item, and amounts to more than the saving in transformers, then three-phase distribution is the proper thing to use. The extreme of this case is a plant carrying power alone and only a few incidental lights, as in an industrial plant.

For transmission lines three-phase is universally adopted, although in stepping down for distribution from transmission lines the current is very often changed to two-phase in order to obtain the benefits of better regulation. This change from two-phase to three-phase, or vice versa, is obtained by what is known as the "Scott system of connecting transformers."

In switchboard work the oil type switch has come to stay. The tendency in low voltage power work is to do away as much as possible with circuit breakers or even fuses, tying everything in tight, the self-induction of the machinery itself saving it from damage by short circuit. Where circuit breakers are needed in alternating current work, the tendency is to equip them with time elements so that they do not act unnecessarily. The limit of the hand operated switch is about 3,000 to 4,000 kw. at 2,200 volts. When generating units or feeders go beyond that capacity or that voltage, power operated switches are necessary. Pneumatic control was first used and now electrically operated distant control switches are the proper thing to use. Switchboard practice, however, is a subject inexhaustible in itself.

In the field of very high voltages there is much yet to be learned. Thorough protection from lighting and static discharge has been worked out, but that is a subject large enough for separate treatment.

Modern practice dictates that all small service transformers shall be of the oil insulated type because of its better ability to stand static strains in lightning storms, which used to play havoc with the old dry transformer. The oil type transformer also runs cooler than the dry transformer.

Although there are a great many core type transformers in use and although they are still being offered for sale, the preponderance of opinion, both in the trade and among consumers, seems to be that the shell type is the better, having less magnetic leakage, hence better regulation, having a further separation of points in the windings, differing greatly in the potential than the core type because there are less turns per layer in its coils. The shell type is more easily repaired in case of break down.

We can undoubtedly say that the single-phase transformer is best and that the three-phase transformers will never be more than a specialty. For a slight saving in the case and core the user of a three-phase transformer has sacrificed the advantage of universal application. In case of break down of one winding all must be taken out of service. In case of the loss of a power customer, the three-phase transformer is of use only in a similar service, whereas three single-phase transformers withdrawn from service in this manner can be used singly elsewhere on the system.

Large transformers for transmission lines are built in three different types. One type is the oil-insulated, self-cooling. This transformer has a corrugated case to increase radiating surface. It is made in sizes up to 500 kilowatts. In larger sizes such transformers are oil insulated, but they are cooled by water which is circulated through a coil of pipes immersed in the insulating oil. The third type is the air blast transformer which is made in all sizes. This transformer is built with air ducts through the core, a blower being used to force air through them to carry off the heat losses. So far as it goes in range of size, up to 500 kilowatts, the oil-insulated self-cooling transformer is best, for there is no cooling agent to depend on. If the heat losses are too great to be carried away by simple radiation, it would seem that water cooling is better than air cooling.

While there may be mooted questions as to the comparative merits of other alternating apparatus, we all agree that the induction motor is the ideal motor. Nothing could be more simple. For constant speed it has no equal.

The induction motor is essentially a constant speed motor just as the shunt wound direct current motor. Nevertheless it is being applied to variable speed work. It answers every purpose for hoisting work, for crane service, elevators, transfer and turn tables. When the load does not continue for a very long time, full load torque and much greater torque at very low speeds can be maintained. There are two methods of securing such speed control. One is to vary the voltage at the primary terminals of a motor having a secondary closed on itself, but having a somewhat higher resistance than the "squirrel cage" winding. This resistance is so proportioned as to give maximum torque at zero speed. Since the torque exerted by such a motor is proportional to the square of the voltage applied, any speed at any torque can be secured by applying the proper voltage, which is secured through a controller from taps brought out from auto converters. The efficiency of the motor at any speed is approximately equal to the ratio of that speed to synchronous speed.

It will be, in fact, a little less. The other method of speed control is to put a winding in the secondary of the motor with collector rings and brushes, which carry off the induced currents to resistances which are varied in value to a controller. This method is slightly more efficient at low speeds, but no more efficient at or near full speed where such motors are usually run in service for any length of time. It has the disadvantage of complicating the motor, turning a rough and ready piece of machinery into a delicate piece of electrical apparatus.

A third method of obtaining speed variation in an induction motor is to change the number of poles in the primary winding by a suitable controlling switch. The fewer the poles the higher the speed. This is the most efficient method, but it introduces too many complications and costs so much in construction that it cannot be said to be standard practice.

Synchronous motors are the exception, not the rule. Even in large units, where their only possible utility lies, they are being discarded for large induction motors. Simplicity is again winning. The synchronous motor has one virtue—constant speed (if generator speed is constant)—but many faults; inability to start under load; inability to vary speed; lack of flexibility; lack of stability under overload. Auxiliary apparatus is necessary, an exciter, a starting motor or compensator. A valuable feature claimed for the synchronous motor is the ability to control its power factor by varying the field excitation. Thus the power factor of a system may be brought to unity, but at a cost no less than that which would have been entailed by the power factor so improved. This feature is of questionable value where the power factor of the circuit varies or where the synchronous motor is controlled by some one other than the operator of the central power house.

Alternating current arc lamps are standard practice to-day in street lighting, because their use enables the central station to use one system for all classes of service, the same generators furnishing current for arc lights, incandescent lights and motors, whereas the old central station had a generator for each kind of load. High generating efficiency is here secured also as compared with the very low efficiency of the direct current series arc machine.

The induction wattmeter deserves mention. This instrument for recording power generated and power furnished is essential in every power plant and for public service corporations and in every customer's house or building. The induction wattmeter has been brought to a high state of perfection and has superseded all the other types.

It has been the purpose of this paper to point out some of those things in which common experience has shown what is the best kind of apparatus to use to meet ordinary requirements in different classes of service. When I say "common experience" I mean the experience not only of the manufacturers but of the users, and such experience is not to be disregarded.

Proposals Invited.

Sealed proposals are being invited until April 19 for furnishing the navy yards at Portsmouth, N. H., and Boston, Mass., with a quantity of arc lamps, rubber-covered wire, conduit and fittings, switch box and other electrical supplies. Bids must be made on Government blanks, which may be obtained upon application to the navy pay offices in Portsmouth and Boston, or the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.

The Secretary of the Interior is inviting sealed proposals until May 5 for furnishing such electrical supplies as may be required by the Government Hospital for Insane, the Geological Survey, Howard University and the United States Capitol, during the next year. Blank forms will be furnished by the Secretary of the Interior, Washington, D. C.

Sealed proposals are being invited until May 5 for furnishing the Government Printing Office with electrical supplies during the next fiscal year. Schedules may be obtained from the Public Printer, Washington, D. C.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 5, 1904.

Electric Railways and Appliances.

756,316. Electromagnetic Railway Switch. Rollin A. Baldwin, South Norwalk, Conn., assignor to the Baldwin & Rowland Switch Company. Filed Dec. 18, 1902. Renewed July 24, 1903.

756,392-756,393. Wheel Guard or Fender. David McCausland, Detroit, Mich., assignor to the Briscoe Manufacturing Company, same place. Filed Oct. 5, 1903, and Dec. 1, 1903.

756,395. Traction-Wheel. James P. McEwing, Drayton, Canada. Filed May 8, 1903.

756,411. Car-Fender. Albert G. Roberts, Peterborough, Canada. Filed Aug. 17, 1903.

756,511. Electric Railway. Thomas D. Lovell, Beverly, Mass., assignor of one-half to Joseph F. Flanagan, Boston, Mass. Filed Nov. 3, 1903.

756,523. Automatic Power Cut-out for Electric Railways. Harry F. Pieper, New York City. Filed Jan. 5, 1904.

756,547. Trolley-Pole. Edwin A. Wakefield and George W. Morse, Mechanic Falls, Me. Filed Dec. 18, 1903.

756,550. Trolley. Charles M. Wilson, St. Louis, Mo. Filed Feb. 18, 1904.

756,757. Third-Rail Electric-Railway System. John D. Wilkens, Chicago, Ill. Filed July 24, 1903.

Electric Lights and Appliances.

756,516. Automatic Electric Cut-out. Guy Milburn, Baltimore, Md. Filed March 31, 1903.

Electrical Machinery and Apparatus

756,335. Current-Motor. Felix H. Crago, Billings, Mont. Filed Oct. 28, 1903.

756,344-756,782. Circuit-Breaker. Leonard L. Elden, Boston, Mass., assignor of one-half to Sears B. Condit, Jr., Somerville, Mass. Original application filed June 20, 1901. Divided and last application filed Dec. 10, 1903.

756,349. Transmission-Gear. Lee A. Frayer, Columbus, O., assignor, by mesne assignments, to the Oscar Lear Automobile Company, same place. Filed Aug. 17, 1903.

756,445. Rheostat. Henry J. Wiegand, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company, same place. Filed June 1, 1903.

756,502. Mechanism for Removing Ice from Electric Conductors. Benjamin J. Jewett, Brooklyn, N. Y., assignor of one-half to Frederick H. Bartlett, same place. Filed Oct. 29, 1903.

756,513. Multiple Motor. Herman W. Martin, Ilion, N. Y. Filed March 2, 1903.

756,534. Circuit-Controller. Jacob L. Schureman, Jr., Chicago, Ill. Filed Jan. 11, 1904.

756,541. Electric Switch Peter Sorensen, Brooklyn, N. Y. Filed Nov. 23, 1900.

756,605. Current-Regulator. Emil Dysterud, Monterey, Mex. Filed June 9, 1903.

756,627. Insulator. John A. Hanson and Albert F. Lambert, Davenport, Wash. Filed June 14, 1902.

756,665. Apparatus for Testing the Insulation of the Coils of Electromagnets. James Livesey, Fall River, Mass., assignor to himself and Robert Healy, same place. Filed Feb. 1, 1904.

756,711. Electric Controller for Alternating Currents. Robert P. Rukenbrod, Turtlecreek, Pa. Filed Jan. 26, 1903.

756,724. Insulator. John C. Snodgrass, Steubenville, O. Filed Aug. 26, 1903.

756,793. Electrical Induction-Machine Hans Lippelt, New York City. Filed Jan. 13, 1903

Telephones and Telephone Apparatus

756,296. Selective Signaling for Polystation Telephone-Circuits. Burdett Stryker, Washington, D. C., assignor to the American Telephone & Telegraph Company. Filed April 30, 1903.

756,331. Spring-Jack for Telephone Switchboards. Merritt S. Conner, Chicago, Ill Filed Jan. 5, 1903.

756,424. Secrecy System for Telephone Switchboards. Edwin H. Smythe, Freeport, Ill., assignor to the Western Electric Company. Filed Dec. 14, 1901.

756,436. Telephony. John Trowbridge, Cambridge, Mass. Filed May 18, 1903.

756,437. Telephone. John Trowbridge, Cambridge, Mass. Filed May 18, 1903.

756,508. Telephone Attachment. Gabor Konigstein, San Francisco, Cal., assignor of one-half to Joseph Silverman, same place. Filed Sept. 8, 1903.

756,608. Annunciator. Franklin H. Elwell, Chicago, Ill. Filed July 9, 1902.

756,777. Electrical Annunciator. Albert Carliss, Chicago, Ill., assignor to the American Electric Telephone Company. Filed Oct. 5, 1901.

Miscellaneous.

756,219. Wireless-Telegraph Receiving System. Eugene Ducretet, Paris, France. Filed Aug. 14, 1903.

756,223. Process of Treating Low-Grade Ores and Tailings by Electrolysis. Ernst Fahrig, Philadelphia, Pa. Filed May 9, 1903.

756,242. Electric Heater. Robert Kuhn, Detroit, Mich., assignor to the United Electric Heating Company, same place. Filed Oct. 7, 1902.

756,275. Electric Signaling Device for Elevators. Fred S. Payne, Boston, Mass. Filed Aug. 11, 1903.

756,408. Call or Alarm Device for Hotels or Other Buildings. Harvey Reed, Minneapolis, Minn., assignor of one-third to William M. Stone, same place. Filed Sept. 4, 1902.

756,441. Massage Apparatus. Arthur Ward, Philadelphia, Pa., assignor to the Electric Thermo-Vibra Company, same place. Filed July 20, 1903.

756,444. Electric Elevator. Harold R. Wellman, New York City, assignor of one-third to Edward S. Isham, same place. Filed June 30, 1903.

756,468. Code-Index. Charles G. Burke, Brooklyn, N. Y., assignor of seven-tenths to John Q. A. Whittemore, Boston, Mass. Filed May 26, 1902. Renewed Aug. 4, 1903.

756,718. Wireless Signaling System. Harry Shoemaker, Philadelphia, Pa., assignor, by direct and mesne assignments, to the International Wireless Telegraph Company and Marie V. Gehring, same place. Filed Aug. 9, 1902.

756,719. Signaling System. Harry Shoemaker, Philadelphia, Pa., assignor, by direct and mesne assignments to the International Wireless Telegraph Company and Marie V. Gehring, same place. Filed Aug. 19, 1902.

THE TELEPHONE WORLD.

Independent Telephone Supply Plant.

A conference of the Interstate Independent Telephone Association has been held in Chicago for the purpose of organizing a telephone supply company with a capital of $1,500,000. The Interstate Association controls several hundred of the smaller Independent companies throughout Illinois, Indiana, Ohio, Michigan and the surrounding States. The plan, so it is stated, is to merge two small concerns at Indiana Harbor, and use them as a nucleus around which to build a big plant that can supply material to all the Independent telephone companies throughout the country.

Officials of the Chicago & Alton Railroad have decided to install telephone lines at all the principal side tracks along the main line between Chicago and St. Louis. These lines will be the length of the siding and will enable a freight conductor at one end of the siding, perhaps two miles distant, to talk to the operator at the station at the other end, and ask for instructions about proceeding. It will save a vast amount of delay, which has occurred in the past and which was caused by conductors walking from one end of the long siding to another. The telephones are to be installed in heavy boxes attached to telegraph poles, and which will be protected by switch locks to keep mischievous persons from tampering with them. The conductors will be able to converse with the agents or operator upon any matter of importance, which will save a long walk.

J. C. Hume, secretary of the Mutual Telephone Company of Des Moines, Ia., has purchased a new multiple switchboard and closed the deal for financing the company. J. H. Hill, of the directory board, stated the Ninth and Locust street location for the building undoubtedly will be chosen. Architects are figuring on plans for the building, the cost of which will be in the neighborhood of $30,000.

The American Telephone & Telegraph Company now has accountants at work preparing a statement to determine the benefits to accrue to the Western Union Company under the decision whereby the United States Circuit Court of Appeals of Massachusetts decreed that the Western Union was entitled to an accounting for shares of stock in the companies licensed by the Bell Company under the contract made in November, 1879.

A number of Independent telephone men of the United States Telephone Company and branch stations between Dayton and Richmond, O., have recently been in the former city in conference for the purpose of constructing a line between the two places. This will give Independent telephone service to Indianapolis and St. Louis.

The Ulysses Co-operative Telephone Company of Jacksonville, N. Y., has the following directors: R. A. Miller, A. H. Wood and Walter Mekeel, all of Jacksonville.

The People's Rural Telephone Company will build its first line from Swedesboro to Mullica Hill, N. J., as soon as contracts can be awarded and material procured.

Steady Growth of Keystone Company.

According to a report from Philadelphia, Pa., the Keystone Telephone Company's earnings for the quarter which closed with March were the largest it has had. The figures were $78,910, against $41,315, for the same quarter last year. The first quarter of the company's existence, the earnings were $19,390, and there has been a gradual advance ever since.

Gainesboro Company's Extensions.

The Gainesboro Telephone Company of Carrollton, Ga., has recently made great extensions in its property. The absorption of the Commercial Telephone Company of Atlanta, with its 90 miles of wire from Atlanta to Jackson and from Atlanta to Senoia, together with links and branches constructed in other parts of the adjacent counties, and the installation of several large exchanges in the towns and cities on its line, made necessary a large office force at the headquarters in Carrollton, and two large apartments have been added to the general office and an assistant secretary and a general auditor employed.

Articles of incorporation have been filed with the Secretary of State for the Renville, Minn., Rural Telephone Company with a capital stock of $20,000, and with authority to connect a number of towns under 2,000 in population by means of rural telephone lines. The towns to be connected are Fairfax, Franklin, Morton, Renville, Olivia, Bird Island, Hector and Buffalo Lake. The incorporators are A. E. Carver, A. E. Rieke, S. W. Smith, Paul Albrecht and C. W. Parsons, of Fairfax, and O. W. Harris and R. E. O'Keefe, of Franklin.

The Whitesboro branch of the Utica, N. Y., Home Telephone Company was put into operation a short time ago, and soon New York Mills and Yorkville will be included in the system. The line is being carried on to Oriskany and will be ready for operation probably by the last of the month. This additional service will be greatly appreciated and is the source of considerable gratification.

Corporation Counsel Duvall has given an opinion to the commissioners of Washington, D. C., to the effect that the Chesapeake & Potomac Telephone Company may charge whatever rate for messages it pleases at the toll stations in that city and in the suburbs. The subject, he says, is uncontrolled by legislation.

The rates of the Franklinville, N. Y., Telephone Company have been advanced from 33⅓ to 50 per cent. The company claims not to have made expenses during the past five years, though the officers have served gratuitously. The new rate is $12 per year for business places, and $9 for residences.

The Seneca Telephone Company of Gibsonburg, O., will operate a telephone system in the counties of Seneca and Sandusky on $20,000 stock.

The Naples Telephone Company has been organized at Naples, Me. Its capital stock is $10,000. J. P. Fickett is president and treasurer.

New Mexico Indians to Have Telephones.

Superintendent Allen, of the Indian School at Albuquerque, has a telephone system for the Indians of the Laguna and Acoma pueblos, situated in Valencia County, under advisement, and that some 46 miles of wire will be strung, and the Indians provided with the greatest of all American conveniences—the telephone. He suggested the plan to them and they were delighted and will do all the work of installing the line, and the Government will be put to but the small expense of furnishing the wire and instruments.

The line will run from Laguna to McCartys, 18 miles; from McCartys to Acoma, 12 miles; Laguna to Pahate, a side line, 10 miles, and Laguna to Mesite, another side line, 6 miles. It will be exclusively for the use of the people of the pueblos. The Indians have always marveled at the telephone and they have already started the work, so enthusiastic are they, and as soon as Mr. Allen can hear from Washington he will start building the line in earnest. It will be the first Indian telephone line in the United States.

There are plenty of telephone lines in the Indian Territory used by the so-called civilized tribes, but this is the first system installed for the use of the bona fide reservation redskins.

The Pleasant Valley, N. Y., Telephone Company has been incorporated to connect Earlville, East Hamilton, Hamilton Village and other points in Chenango, Madison and Oneida Counties. The directors are C. Frank Foster and L. W. Knapp, of Earlville; George W. Berry, of Poolville; C. S. Munson, of East Hamilton; H. C. Williamson and S. A. Fitch, of Hamilton.

At a mass meeting of citizens of Nuckolls County, held recently at Nelson, Neb., the Nuckolls County Telephone Company was organized with a capital stock of $50,000. The company will establish a system of rural telephones throughout the county.

The Pelican Telephone Company, organized to operate a telephone exchange in Pelican Rapids, Minn., and other adjacent territory in Otter Tail County, has a capital stock of $25,000, and its officers are: J. P. Wallace, president; C. M. Carr, vice-president; N. P. Meen, secretary, C. L. Ward, treasurer.

Telephone Incorporations.

The New York Automatic Telephone Company, Passaic, N. J. Capital stock, $1,000. Incorporators: Charles R. Newman, George Roegner and Adolph C. Gilgen.

The Utica Telephone Company, Utica, Wis. Capital stock, $5,000. Incorporators: J. G. Pickett, A. Parks, R. W. Mackie and W. F. Muncil.

The Mondovi Telephone Company, Mondovi, Wis.—to construct and own telephone lines. Capital stock, $240,000. Incorporators: B. S. Lockwood, George A. Duetscher. S. D. Hubbard and C. W. Gilman.

The Dundee & Crystal Springs Telephone Company, Dundee, N. Y. Capital stock, $5,000. Incorporators. Delmar J. Knapp, L. Pitcher, Ed. J. Bailey, all of Dundee.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Anadarko, Okla.—The election held here recently to vote on the proposition to issue bonds to the amount of $30,000 for a sewer system and electric light plant was carried.

Baltimore, Md. M. Solmson & Co., of this city, are erecting a woodworking plant and are in the market for woodworking machinery, a 50 hp. engine, electric light plant, etc.

Bartlett, Tex.—It is reported that the council will be petitioned for an electric light plant franchise. Power would also be supplied to Granger and Holland.

Bedford, O.—The People's Electric Light Company has been acquired by E. A. Mandeville and Edward Roberts, who represent a Philadelphia syndicate. The plant will be enlarged.

Breckenridge, Mo.—O. J. Chapman, mayor, says that a vote will be taken on the construction of a $10,000 electric light plant.

Buchanan, Mich.—Electric lighting is favored by the recently elected town officials, of which B. R. Desenberg is president.

Dayton, O.—The board of public service has ordered additional arc lights placed at various street corners.

Farmington, Mo.—George M. Wilson, mayor, states that an electric light plant will be constructed. Samuel L. Asbury is city engineer.

Greenville, Mich.—Several councilmen favor a plan to issue $26,000 bonds for a municipal electric lighting plant.

Guadalajara, Mex.—The municipal authorities have made a new contract with the local electric light company to very largely increase the public lighting of the city, which has become absolutely necessary.

Hannibal, Mo.—The Electrical Supply Company of St. Louis will erect an electric light and power plant here.

Harvard, Neb.—J. J. Keefe has been granted a 20-year electric lighting franchise.

Henning, Ill.—Robert Wilson, of this city, has purchased the Potomac electric light plant. He will at once make preparations to light this city with electric lights.

Hutchinson, Kan.—The Street Railway Company may install an electric lighting plant. Local business men are also considering a project to erect a plant.

Kendallville, Ind.—A new system of electric street lighting is under consideration. James Graves, mayor,

Lawrenceburg, Tenn.—An electric lighting proposition is under consideration by the town board.

Limestone, Me.—Active steps will soon be taken to have an electric light plant installed here.

Naples, N. Y.—W. H. Tobey, a business man of this place, has obtained from the village fathers a franchise for the erection of poles and the stringing of wires for the purpose of supplying electric light.

Neenah, Wis.—The Wisconsin Traction, Heat, Light & Power Company, of which John I. Beggs, of Milwaukee, is the head, has secured 10-year franchises for lighting this city and Menasha, each paying $5,000 apiece a year for lighting.

New Haven, Ind.—A municipal electric lighting plant is under consideration. J. M. Jackson, town clerk, may be addressed.

Omaha, Neb.—The Omaha Electric Light & Power Company will expend $75,000 in improving its plant. New machinery will be installed.

Roswell, N. M.—Maynard Gunsul, of Albuquerque, representing a company of New Mexico capitalists, of which he is a member, recently secured from the council of this city a 30-year franchise for an electric light and power plant here with a liberal 10 year contract from the city for all street lights needed.

Rulo, Neb.—This city has voted for waterworks and electric light bonds.

Shenandoah, Ia.—The Shenandoah Ice Company has been granted a 25-year franchise for a heating, electric lighting and power plant. Boilers will be required and other apparatus. Address W. F. Hand, manager.

St. Louis, Mo.—The Ada Electric Light & Power Company, lately incorporated with a capital of $40.000 by Allen B. Patterson, William F. Klanke and others, will operate light, power and traction plants.

Suttons Bay, Mich.—This town has a petition before it for granting a 25-year franchise to an electric light company.

Tannnersville, N. Y.—The electric light question is under discussion here. J. D. Hasbrouck, vice-president of the Otis & Catskill Mountain Railway, and Messrs. A. Atkinson and A. Anderson, electrical experts, are interested in the movement.

Topeka, Kan.—The council committee reports that $18,548 will be needed to enlarge the electric light plant to provide power for 75 new lamps. The plan is under consideration.

Yorkville, N. Y.—The issuance of bonds to the amount of $150 for additional electric street lights has been favorably voted upon.

Zacatlan, Mex.—An electric light and power plant is to be installed in this city, located in the State of Puebla. The plans have been submitted by the city council to the State Department for formal approval.

STREET RAILWAYS.

Almont, Mich.—Q. A. Thomas is interested in an electric railway to be erected here.

Anderson, Ind.—The survey of the proposed Anderson-Lebanon electric line, promoted by Wallace B. Campbell, will soon be made by the chief engineer for a New York firm, which has promised to back the project should the survey be satisfactory. The report will be passed upon by the Municipal Bond & Securities Company of Cincinnati.

Bangor, Me.—William D. Smith, of this city, will soon commence work on the construction in Rock Island of the Providence & Newport Electric Railroad.

Chester, Pa.—The Chester Traction Company will greatly improve its system.

Flint, Mich.—The council has given an electric street railway franchise to T. E. Tarsney, T. Nester and J. Russell, of Detroit, for the Detroit, Flint and Saginaw Line, to connect with the Detroit United in this city.

Fresno, Cal.—The Fresno Traction Company will vote May 18 on the issuing of $5,000,000 for extensions.

Geneva, Ind.—The Geneva Traction Company has been organized by fifty residents of this place with a capital stock of $2,000. The company intends to construct an electric railroad, running from here through the counties of Wells and Blackford, terminating on the west at Montpelier. On the east the line will be extended to Celina. O. The directors of the company are Charles D. Porter, J. H. Hordison, D. M. Shively, A. G. Briggs, E. F. Walsh, S. W. Hale and W. J. Heenter.

Glens Falls, N. Y.—The Keeseville, Ausable Chasm & Lake Champlain Steam Railroad is to be converted into a third-rail electric road. The plans have been completed and work is to begin soon. Power will be obtained from a dam across the Ausable River. A new turbine wheel will be installed and 1,200 hp. will be developed.

Indianapolis, Ind.—Fifty feet of the tracks of the Northwestern Traction Company were washed away by the recent flood.

Jackson, Miss.—The interurban electric railroad between Jackson and Vicksburg is going to be built by the Mississippi Land & Investment Company.

Kansas City, Mo.—G. M. Walker and W. B. Strang are promoting a new electric railway here.

New Haven, Conn.—President C. S. Mellen, of the New York & New Haven road, in outlining his plans for developing the electric system in this city, which the road that he represents has just acquired at a cost of $7,000,000, announced last week that through trolley service between this city and Waterbury without change of cars would be established soon.

Palo Alto, Cal.—This city is to have a new electric railway. J. F. Parkinson is the holder of the franchise.

Platteville, Wis.—Patrick Flynn states that a new electric road will be built here this summer.

Smyrna, Pa.—Superintendent Letherbury, of the Middletown & Odessa Electric Railway Company, and E. R. Cochrane, Jr., are engaged in securing the options on the land for the right of way for the extension of that line from Middletown to this place.

Springfield, Ill.—A. G. Kingman is interested in the electric road to be built from this city to Peoria.

POWER PLANTS.

Defiance, O.—M. W. Steinberger, engineer, states that a plant for developing water power on the Auglaize River will be erected soon.

Fremont, O.—The Fremont Power & Light Company, with capital stock of $350,000, has been incorporated by Henry Boozer, of Waterloo, who will establish a water power electrical plant in Belleville, one mile south of Fremont on the Sandusky River.

BIDS WANTED.

Hillsboro, O.—Sealed proposals will be received by J. C. Sprague, chairman of the light committee of the village, until April 30, for the furnishing of electric arc lights for the public lighting; also incandescent lights for private consumers for a period of 10 years. H. P. Morrow, president of council; C. D. Doggett, clerk.

NOTES FCR INVESTCRS.

Latest quotations for copper are: Electrolytic, $13\frac{1}{8}$@$13\frac{1}{4}$c.; Lake $13\frac{1}{4}$@$13\frac{3}{8}$c.; casting, 13@$13\frac{1}{8}$c.

Electric Storage Battery advanced $1\frac{3}{4}$ points in Philadelphia on Monday, later receding $\frac{3}{4}$ on the sale of an odd lot.

The Brooklyn City Railroad Company has declared the regular quarterly dividend of $2\frac{1}{2}$ per cent., payable April 15.

The capital stock of the Crocker-Wheeler Company, of Ampere, N. J., is to be increased from $1,000,000 to $2,000,000.

The New Jersey Short Line Railroad has let a contract for 36 miles of double track electric railway on the short line from Philadelphia to New York for $2,225,000.

From July 1 to March 31 the gross earnings of the Brooklyn Rapid Transit Company show an increase of about $900,000, as compared with the same period last year.

The United Traction Company of Albany, N. Y., has declared the regular quarterly dividend of $1\frac{1}{4}$ per cent., payable May 1. Books close April 20 and reopen May 2.

It is understood that Judges Grosscup and Jenkins of Chicago now have the full case of the ninety-nine year franchise arguments under review. A decision in the case is expected next week.

The United Electric Securities Company of Boston has declared its regular semi-annual dividend of $3.50 per share, payable May 2 to stock of record April 20. The books do not close.

The Milwaukee (Wis) Electric Railway & Light Company has declared the regular quarterly dividend of $1\frac{1}{2}$ per cent. on its preferred stock, payable May 2. Books close April 20 and reopen May 3.

Owing to the sharp advance just before the close of the market in Wall Street on Monday Brooklyn Rapid Transit advanced to $48\frac{1}{8}$, where it closed with a net gain for the day of two points.

The United Traction Company of Albany, Troy and Cohoes, has made application to the New York Railroad Commission for permission to issue the mortgage of $6,500,000 approved by the stockholders.

The Northern Electric Company of New York was incorporated at Albany on Monday with a capital stock of $10,000. The directors are T. J. Ryan, Lucien Barnes, Jr., and G. A. Schriefer, of New York.

The Union Traction Company of Columbus, O., has amended its charter so as to increase its capital stock from $10,000 to $700,000. It is to operate electric lines from Cincinnati to Toledo, Columbus and Zanesville.

The Hudson River Telephone Company, Albany, N. Y., has declared the regular quarterly dividend of $1\frac{1}{2}$ per cent., payable April 15. Hereafter dividends will be paid on January 15, April 15, July 15 and October 15.

While there is less active buying of copper on either domestic or foreign account, the market continues strong at full prices; in fact it is difficult to buy even small lots at inside quotations, while a round lot of any kind would be difficult to purchase this side of June.

The directors of the American Telephone Company have not reached a conclusion with respect to their financial plans. For some time they have been "sounding" important financial interests with respect to an issue of bonds, but to date they are not in a position to make a definite proposition to bankers.

ELECTRICITY.

VOL. XXVI. NEW YORK, APRIL 20, 1904. NO. 16.

ELECTRICITY.

Published every Wednesday by the ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.

Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:

United States, Canada and Mexico..$1.00
Foreign Countries.......................... 3.00
Single Copies.........................10 cents

Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.

Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

An Article Worthy of Study. It is seldom that we refer in these columns to articles in the body of the paper. We do not as a rule believe in it because it takes up space which might advantageously be utilized for other matter. There are exceptions to every rule however. We therefore call our readers' attention to the first installment of a most interesting series of articles on the systematic classification of the underlying principles of wireless telegraphy, which will be found elsewhere in this issue of ELECTRICITY.

This resume, by the well-known writer Emile Guarini, from the noted address of the French scientist, M. Ferrie, is from the standpoint of simplicity, clearness and scope the best, we believe, of its kind ever published in our language, and it is well adapted to meet the desires of those of our readers who wish to keep posted in the development of this interesting and rapidly growing department of electricity, and it will undoubtedly "furnish food for thought" for many of our inventors who may have been somewhat blindly groping after a clear, well-defined base of operation.

* * *

Letter-Press Printing by Electrolysis. While investigating a process for letter-press printing by electrolysis without the use of ink (an extension of Bain's telegraphic printing) Mr. Charles R. Darling, of London, found that the final results of electrolysis—when the electrolyte forms only a thin film—often differ materially from those observed in an ordinary cell. In the course of his experiments, which he has lately brought before the Faraday Society for discussion, Mr. Darling used a carbon or metal plate (it was immaterial), which formed the anode; on this was placed an impression pad, consisting of some sheets of moist blotting paper; upon this was the trial sheet, carrying the electrolytic film, and on this the cathode type or coin. Voltages from 6 to 200 were employed. It was requisite, in order to obtain a clear image of the type, to use a certain minimum strength of solution. The first experiments were made with saline solutions; silver nitrates gave a clear, permanent black image of the type, but the paper of course darkened on exposure; copper sulphate and nitrate yielded images that faded after a time; the same unexpected result occurred with lead, mercury salts and bismuth. The best images were obtained with manganese salts. These consisted of the oxides or hydrates, and were thus quite permanent; all purely metallic deposits, excepting silver, disappeared after a time.

In the case of non-saline solutions, the paper, which might consist of asbestos or pure Swedish filter-paper soaked in distilled water, acquired the properties of an exposed photographic plate, and on treating with a silver salt and developer a perfect image of the cathode was obtained, even after a long interval. Mr. Darling showed productions of such electrographs to his audience. The latent images are not due to hydrogen peroxide, nor to metallic compounds as they occur with carbon electrodes, but they reside in the surface of the paper in contact with or towards the cathode. They are ascribed by Mr. Darling to a class of phenomena that have been investigated by Bose, and termed "the response of inert matter to electrical stimulus." He is of opinion that they are probably the result of some state of strain set up in the film by the current. It was remarked that the fading of the metallic images may be simply due to recombination, but that explanation

was not regarded as entirely satisfactory. A number of questions of interest were asked in the course of the discussion. Mr. H. J. Bluman said that in some experiments which he had carried out with electrolytic printing he had used some organic solutions with good results, but Mr. Darling replied that they eventually discolored the paper. In replying to other speakers he did not think hydrogen was the cause of the latent images, and certainly hydrogen peroxide does not destroy the image.

* * *

Growth of Electric Railways. Some idea of the wonderful growth of street railways in this country during the past decade, due principally to the introduction of electricity, may be had from some statistics published in Poor's Manual. In 1894, according to this authority, there were 13,176 miles of street railways in operation, whereas in 1903 there were 24,561 miles, or an increase in ten years of 11,384 miles.

This growth would not have occurred had electrical inventors not been constantly at work perfecting every detail of street railway apparatus. To what extent electric traction has increased during the years between 1894 and 1903 may be had from the following figures: In 1894 there were 1,950 miles of street railway operated by animal power, while in 1903 the mileage had been reduced to 281. In 1894 there were 578 miles of cable road while in 1903 there were but 267. In 1894 there were 10,238 miles of electrically operated roads, whereas last year there were 23,869 miles, an increase in ten years of 13,631 miles or more than double the mileage the country boasted of previous to 1894.

The distribution of traction mileage shows that more than half of it is confined to seven States. New York leads with 2,879 miles, while Ohio is a close second with 2,872 miles, followed by Massachusetts with 2,649, Pennsylvania with 2,487, Illinois with 1,901, California with 1,110 and Missouri with 835 miles. Of the horse traction remaining 124 miles are in New York, 43 in California, 34 in Pennsylvania, 14 in Illinois, 11 in Missouri, 8 in Massachusetts and none in Ohio. In fact, outside of a few centers where electrification is in rapid progress, horse traction has become obsolete. On January 1 of this year there were 267 miles of cable traction still in use but there was not a mile of it in this State. There is more of it in California, 82 miles, while important systems remain in Chicago, Philadelphia and St. Louis. Electricity having been demonstrated to be more economical than cables, it is fair to assume that it will rapidly replace the latter, except in cases where peculiar conditions make the cables more desirable.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

It costs the Brooklyn Rapid Transit Company more than $1,000,000 a year to pay the claims for damages which are made against it.

Signor Marconi, who is at present in London, says that, as soon as the agreement with the British Post Office is signed, the wireless service for Canada and the United States will be started.

The various organizations of employes of the elevated railroads in New York have voted to reject the pension plan proposed by the Interborough Rapid Transit Company.

The city of Alexandria, Va., is now arranging to sell its electric lighting plant to private parties. It owns an electric plant which supplies only arc lights and an old gas plant which furnishes gas for domestic lighting. The authorities will in a short time advertise for sale the exclusive franchise for using the streets for electric lighting and power.

The Chicago Telephone Company was dealt a stunning blow by Judge J. W. Mack on Friday last when the court held that the corporation was a tenant of the city as the city exists to-day and not as the city existed in area in 1889 when the company was given its franchise. The ruling was in the suit brought by the Alton Grain Company contesting for the telephone company's right to charge more than $150 for its service within the present limits of Chicago. The decision, if sustained, will also mean increased compensation to the city as the company is paying only on its earnings within the old limits of the city.

The Electric Railway Test Commission, which is composed of J. G. White, New York, chairman; H. H. Vreeland, W. J. Wilgus, and J. H. McGraw, New York, and G. F. McCulloch, Indianapolis, has announced the plans for the elaborate series of electric railway tests to be made during the St. Louis Exposition. On the grounds of the exposition the authorities will provide special tracks having an almost level grade and well ballasted, for the operation and testing of railway car and locomotive equipments. These special tracks consist of one section 1,400 feet in length, and one section 2,000 feet in length, the two sections being parallel. Upon these tracks it is proposed to carry on the greater part of the operating, acceleration, braking, coasting and motor-heating tests, as well as tests to determine car and train friction.

An English paper states that specimens of a new thorium ore have been discovered in Ceylon and forwarded by the Government of that colony to the Imperial Institute. The specimens received were small black cubical crystals, and it was at first thought that they were uraninite or pitchblende. The specific gravity of the mineral was found to be 9.32, and analysis showed that it was not pitchblende, since it contained only about 12 per cent. of uranium oxide and 75 per cent. of thoria.

It is stated that nine persons out of every ten who use the telephone hold the receiver to the left ear, and many find it impossible to hear over the telephone with the right ear. The fact that the majority of men and women are right-handed and that the constructors of the first telepones took due notice of this is responsible for this new condition of left-eared people.

Consul C. R. Slocum at Warsaw, Russia, reports to the Department of Commerce and Labor that the proposed electrical exhibition has been cancelled, owing to the belief of the promotors that pending the duration of the Russo-Japanese conflict such an exposition would not pay.

Another patent on a marine compass has recently been taken out by Lord Kelvin. According to the *Electrical Engineer*, London, the patent covers an improvement in the method of suspension to secure a steady card in spite of greater vibration due to higher speed in steamships. Another feature is the illumination of the compass at night entirely from the underside. This can be done either with electric light or by means of oil lamps. In either case adjustment in the intensity of the light is provided, as this has been found particularly useful when taking bearings from stars or other faint lights. A new form of helmet is now introduced having rifle sights upon the top. This helmet moves around freely in any direction, and bearings of the sun, lights, buoys or other objects are taken instantaneously and read directly upon the compass card.

THE LATEST PROGRESS IN WIRELESS TELEGRAPHY.*

BY EMILE GUARINI.

Translated for "Electricity" by Jean A. Wetmore, M. S., E. E.

A leading French authority, M. Ferrie, a member of the Central Commission of Wireless Telegraphy of the same country, and who is known as an author of very interesting works pertaining to this class of telegraphy, has just submitted to the Parisian International Society of Electricians a very remarkable paper under the above title, which is very worthy of attention in several respects. It is pre-eminently a very able resume of the present state of the subject and furthermore, we find among the observations and criticisms, the descriptions of new devices, those which may be of great practical and theoretical utility. But the most remarkable portion of M. Ferrie's paper pertains to the comparative study of the various systems and of the various methods, which are grouped around those systems, and what makes this dissertation more remarkable, and still more worthy of attention, is that it is not based solely on theoretical data, but upon results obtained from the comparative experiments made by the author with the various systems.

The progress made in wireless telegraphy during the last two years has been, according to M. Ferrie, of little importance, for, in spite of the numerous investigations and installations, made in various countries, the difficulties in its use have persistently remained the same as before.

In his opinion the numerous experiments made with the various devices have at least resulted in fixing in a concise way the present status for the possible conditions to be met in the practical development of tele-communication. Theoretical ideas are likewise well defined.

M. Ferrie has passed in review the various hypotheses regarding the propation of waves, but he rounds off the theory submitted by M. Blondel in 1898. In accordance with the latter, the antenna-earth system is the equivalent of a double length Hertz oscillator, obtained by the prolongation of the antenna O A, by a symmetrical part O A', which is considered as an "electrostatic image," in respect to the surface of the earth, while the latter plays the role of a surface conductor. The field created by this rectilinear oscillator is formed in all respects like the field investigated by Hertz, which surrounds a small rectilinear electric oscillator, forming and giving out a series of rings, which become detached and are carried perpendicularly to the wire of the oscillator, at the same time increasing in size (Figs. 1, 2, 3).

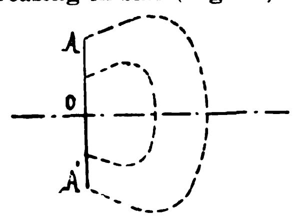

FIG. 1.

Several English and American writers have admitted that these rings are reduced to halves, the presence of the earth only permitting of the existence of the upper halves, which are carried along by a simple translational movement, maintaining meantime their relative contours (Fig. 4). According to M. Blondel this cannot be admitted, because the lines of force tend to extend in all directions; they consequently increase in height at

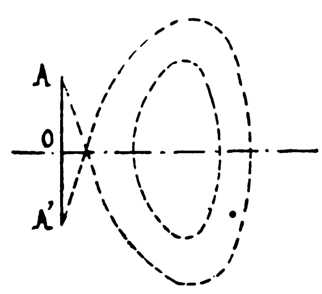

FIG. 2.

the same time as they move along the surface of the earth, on which they are normally supported (so to speak), at the same time they curve inward toward the vertical axis (Fig. 5), similar to the results obtained from the study, within short distances, of the Hertzian field.

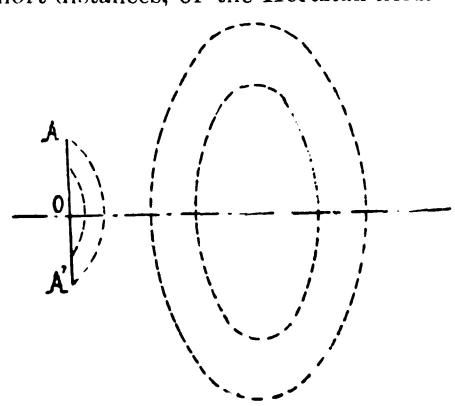

FIG. 3.

We should consequently represent the propagation of the lines of force in a diagrammatic manner, as shown by Fig. 5.

We will here remark that this theory must be considered as somewhat novel, rather than as a complement of the preceding theory, as stated by M. Blondel; whichever it may be there is a considerble difference between them. Although M. Blondel in his first theory admits of an electric perturbation, "an electric mist or fog," brought to a maximum at the height of the transmitting antenna, it actually admits of a propagation above the transmitting antenna, which hypothesis agrees in other respects with the experiments made by M. Ferrie in a liberated balloon and also with the investigations of others.

We would have liked very much to have had M. Ferrie discuss further the other proposed theories. Being certain of our more recent experiments, substantiating in effect the other belief, which is

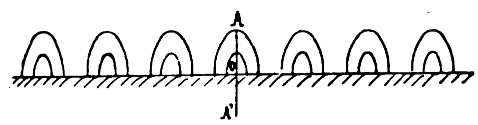

FIG. 4.

that contrary to the opinion, which he has held to for several years, the conductivity of the earth or of water on one side, and that of the atmosphere on the other, and that each plays its part at least over long distances. Concisely stated, it really is a circuit, composed of two conductors, water or the earth, and the atmosphere, which are in imperfect contact, similar, for example, to the rails of a railroad in the track circuit. The atmospheric layer, as it pertains to the phenomenon is, as M. Blondel states, in his first theory, limited to the heights of the antennæ.

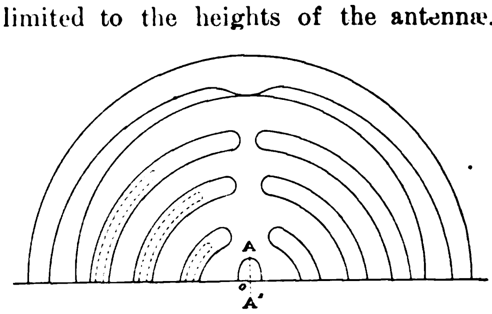

FIG. 5.

This does not prevent a propagation in all directions through an electrostatic and an electrodynamic induction. This induction is appreciable at relatively short distances, and it easily explains the effects produced in the free balloon experiments. Whatever it may be due to, M. Ferrie deduces, as a result of M. Blondel's new theory, that the energy transmission per unit of surface, varies proportionally to the factor

$$\frac{1}{\alpha^2}\;\frac{\cos^2\left(\frac{\pi}{2}\cos\theta\right)}{\sin^2\theta}$$

in which θ represents the angle of propagation with the vertical, and α the dis-

*Resume of a paper by M. Ferrie.

tance (Fig. 6). From this we find that the energy varies in inverse proportion to the square of the distance, and furthermore that it should decrease rapidly with the height above the horizon, but the effect produced upon the coherer is proportional to the energy produced in the receiving antenna and consequently to the energy per unit of surface. Furthermore, according to M. Ferrie, M. Blondel's new theory appears to be quite

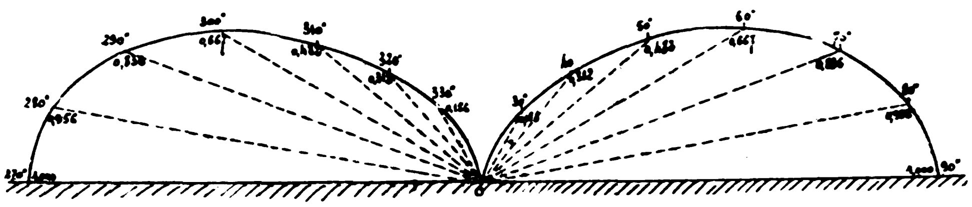

Fig. 6.

rational and in accordance with observed facts. Theoretical investigations have likewise been made for the purpose of determining the solution of the problem of syntonization in a scientific manner. The first attempts were made to accurately measure the period of the oscillations produced at the transmission end. The direct methods requiring delicate and complicated devices, being practically of little use, it is preferable to have recourse to indirect methods, which consist in employing an auxiliary circuit, which is placed in resonance with the discharging circuit, as has been done by Lecher and Hertz.

M. Drude made up the auxiliary circuit by using two parallel wires connected by a movable bridge, the Hertz resonator being then replaced by an empty tube in connection with the bridge. A different method was employed by M. Ferrie. It is known that every conductor connected in an oscillating circuit itself partakes of the vibration; the oscillations of which it forms a part, have their maximum amplitude when its electric elements

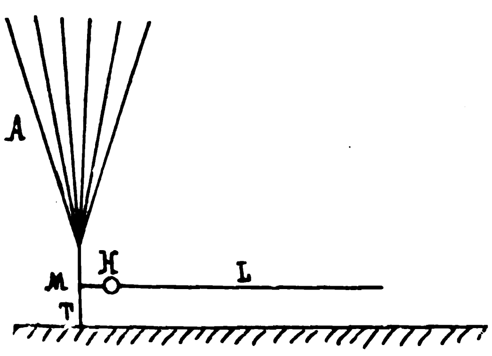

Fig. 7.

are such that its own period becomes equal to the period of the exciting circuit.

More specifically, if we connect a well insulated horizontal wire, L, to an antenna, A (Fig. 7), at a point, M, near the grounding point and a thermic amperemeter, H, be inserted in the horizontal wire near the point of derivation, and the antenna be put into a state of vibration, by any available means, the following facts will be observed: On progressively increasing the length of the wire, L, the intensity, as indicated by the amperemeter, will likewise progressively increase up to a very well defined maximum, afterwards it decreases to a value approaching zero, to afterwards again increase, and so on. The consecutive maximums and minimums are equally spaced and the absolute value of the maximum continues to rapidly decrease.

The effective intensities, as measured by the ampere-meter, are evidently those of the stationary waves which are produced in the horizontal wire.

The length of the wire, which corresponds to the first maximum, consequently represents a quarter of a vibratory wave movement of the antenna, since the horizontal wire and the antenna at this moment are in unison with each other. By employing at all of the stations and for all forms of antenna a horizontal wire identically the same, placed at the same distance from the ground, the quadruple of the lengths of the horizontal wire, corresponding to the first maximum, may be considered as the wave length.

This method, which M. Ferrie has employed for two years past, has been recently modified, and, we remark in passing, by M. Slaby, who replaced the auxiliary rectilinear wire by a solenoid. M. Ferrie believes that the results thus obtained are not in all cases comparable; at any rate M. Ferrie has proven by his method, using a captive balloon, that the rule of the quarter wave for antennæ, connected to a single wire, which are directly excited, are very appreciably exact, up to a distance of 800 meters. With antennæ of 800 meters length the frequency of the oscillations are not greater than 100,000. It is interesting to note that the properties of these waves are identical with those having a period of one hundred times greater. M. Ferrie believes that it is allowable to admit that it is the same for oscillations having a period much less. This was demonstrated by the writer of this article elsewhere several years ago.

According to his idea this provides an explanation for certain ruptures in alternating current transmission cables, which is explained by the formation of stationary waves, originating from the high harmonics.

M. Ferrie has also observed that the length of the wave noticeably increases with the number of wires composing the antenna, and especially with their separation.

If indirect excitations are employed in the transmitting instruments, i. e., the inductive method, it will be observed that the antenna vibrates in unison with the period of the exciter circuit, and it does not have a constant period but one of its own. This, in the writer's opinion, is of importance for the purpose of securing secrecy of transmission and explains the ineffectiveness of syntonization in the greater number of cases, since the same thing occurs between the transmitting antenna and the receiving antenna. The energy of the oscillations are evidently at a maximum when they are in unison and this unison may be found by adjusting the elements of the exciter circuit until the thermic ampere-meter, which is this time placed in the antenna circuit, near the

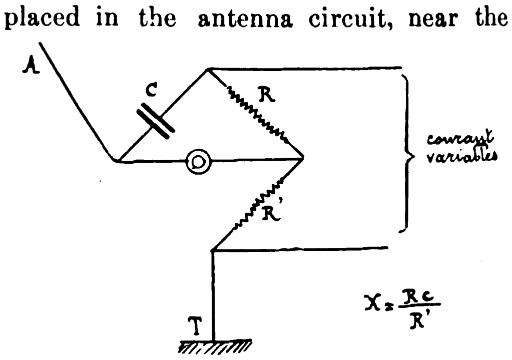

Fig. 8.

ground, indicates a maximum. We will also observe that the "intensity" is capable of attaining three or four effective amperes, by making use of induction coils, the maximum intensity of the oscillation is then in the vicinity of the 100 amperes.

It would be equally interesting, as M. Ferrie has observed, to compare the variation in capacity with the variation in the length of the wave, due to modification in the forms of antennæ, all of the same length. These capacities are easily measured in a sufficiently accurate manner by the Thomson or the De Santy methods, in which a telephone is employed as a zero device, using variable currents (Fig. 8), the latter being received in derivation from the terminals of a Rhumkorff coil primary, care being taken to insert into the shunt circuit some low capacity condensers or some strong self-induction.

It is thus observed that the capacities of ordinary antennæ are several 1,000th of a microfarad. For example, a single wire

antenna, 30 meters long, has a capacity of 25-100,000 of a microfarad. By varying the number and the separation of the wires, composing an antenna of given length, and by measuring the capacity in each instance, and the length of the wave, we observe, by applying the Thomson formula—if, however, it can be applied—that the self-induction varies but very little whatever may be the number of the wires.

(To be continued.)

ELECTRIC TIMIMG ARRANGEMENT ON THE "CRESTA" AT ST. MORITZ*.

Most people have heard of the celebrated "Cresta" toboggan run at St. Moritz, Switzerland, and many have seen it, but not so many are familiar with the electric arrangement by which the racing is timed accurately to the tenth of a second. Having regard to the unique character of this

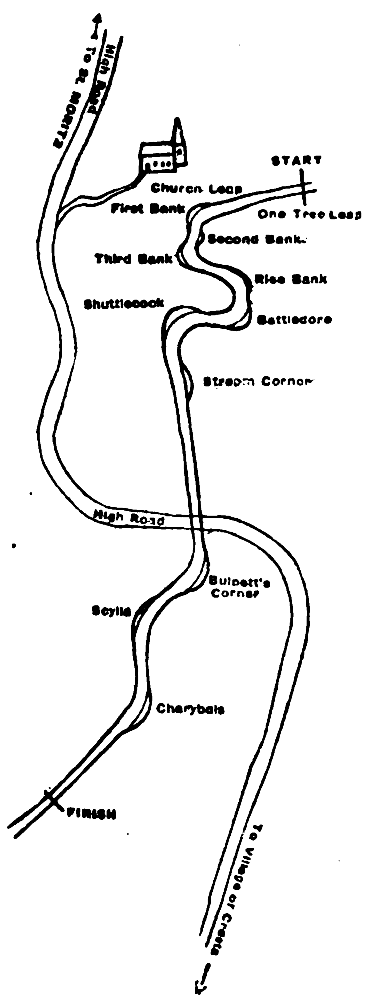

Fig. 1.

little installation, a description of the apparatus may be of interest to electricians.

St. Moritz is one of the highest villages in the Engadine, having an altitude of about 6,000 feet, and is a great center of winter sports; it is consequently much frequented by English and other nationalities who enjoy the sports of skating. curling, tobogganing, ski-ing, bandy, etc., which can here be obtained under

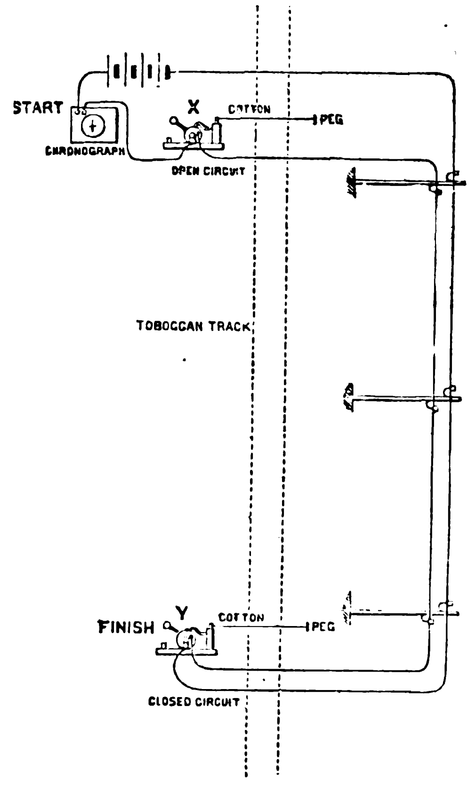

Fig. 2.

the best conditions. Good tobogganing may be had in other places, but at St. Moritz it is carried to a fine art, and only an expert can expect to compete successfully on the renowned "Cresta" toboggan run, with its wonderful curves and banks. The name Cresta is derived from a small village of that name near the finish of the course.

Fig. 1. gives a rough outline of the course, which is a little over three-quarters of a mile in length, with a difference of elevation from the start to finish of about 600 feet; the gradient varies at different points, being most steep at the church leap.

As only one toboggan can occupy the track at a time, the races are all decided by the time taken to complete the course. The record time from the start to the finish is at present $61\frac{6}{10}$ seconds, this entailing a speed of 60 miles an hour or more on the fastest parts. The curves of frozen snow are built up with high banks accurately shaped to allow the tobogganer to go round them at the greatest speed, the highest bank being about 25 feet in height. These different banks have well-known names, such as the Battledore and Shuttlecock, Scylla and Charybdis, Bulpett's Corner, etc. The whole track is practically of ice, and after passing the finish it has for a short distance a steep upward gradient, the great momentum obtained carrying the tobogganer up hill.

The toboggans used are of the "skeleton" pattern with steel runners, the tobogganer lying in a prone position and steering with his feet, by means of spikes attached to the toes of his boots. The principal race run on the Cresta is the "Grand National," which takes place at the end of February, or beginning of March, and might be called the "Derby" of tobogganing, competitors coming from Davos and other places to take part in this contest.

At the side of the course there are poles carrying four overhead wires on ordinary porcelain insulators; the two upper wires are connected to a telephone at each end to allow of communication between the officials in charge of the starting and finishing points. The two lower wires are connected to the timing apparatus, which is arranged as in Fig. 2.

At the starting point, one overhead wire is connected through a battery of 10 cells to one terminal of the chronograph, the other terminal being connected through the trigger switch X to the other overhead wire. The further ends of the overhead lines are connected at the finishing points to another trigger switch Y.

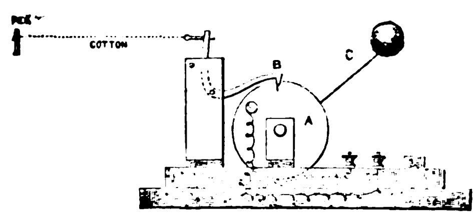

Fig. 3.
Switch with Trigger Set and Attached to Cotton.

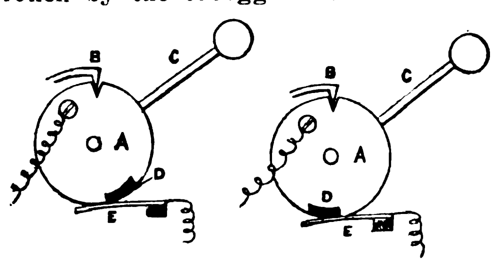
Both switches X and Y are firmly fixed at the side of the course, and have each a strong cotton line attached, with one end to the trigger of the switch; the line is stretched across the track about $2\frac{1}{2}$ inches from the ground, and the other end is tied to a peg driven into the ground on the further side.

The switches X and Y are nearly identical, and are represented in Fig. 3. A circular wheel of brass, A, is mounted on bearings and has a notch in its periphery in which the pawl B is placed when the trigger is set. To the wheel is fixed a radial arm, C, with heavy brass bob, which falls by gravity when the pawl is disengaged by the cotton being pulled. At the lower edge of the wheel, A, a piece of ebonite, D, is inserted in slightly different positions in the two switches (Fig. 4); also a metallic spring contact, E, is pressed against the under side of the edge of A.

As will be seen in Fig. 4, when the

*From the "Electrical Review." London

pawl is set in the notch in the two switches, the spring E in switch X will be pressing against the ebonite, D, and in switch, Y, the spring, E, is making contact with the wheel, A Before the tobogganer starts, both switches are set with the pawls, B, in the notches of the wheel, A, and the cotton stretched from the trigger across the track at start and finishing points. The signal is given and the tobogganer starts from a few yards behind the cotton; his toboggan striking the cotton pulls and breaks it, disengaging the pawl; the arm, C, drops at switch, X, closing the circuit, which allows the current to flow through the electro-magnet of the chronograph, the armature releasing the clockwork, which immediately starts and continues until the cotton attached to switch, Y, is pulled and broken by the toboggan at the finish of



Switch Y Circuit Closed. Switch X Circuit Open.

FIG. 4.

the course, when the arm of switch, Y, falling breaks the circuit and stops the chronograph; the time is then noted, and the apparatus reset for the next tobogganer. The chronograph has a stop for resetting the hand at zero, one complete revolution of the hand representing 30 seconds and these being subdivided into tenths.

It may be mentioned that with the switch at the starting point, the pawl, B, can be arranged so that a comparatively hard pull is required to disengage it, but at the finishing point, owing to the very great speed of the toboggan, the pawl must be arranged so that a light pull will disengage, or otherwise the cotton will break without releasing it.

ELECTRICAL STATION PRACTICE.

ARTICLE XXXIII.

BY W. H. RADCLIFFE.

The testing of the generators in an electrical station necessitates certain resistance measurements being taken among which are those of the armature winding and field winding mentioned in the preceding article. These measurements are best made upon a Wheatstone bridge, and for station work the portable form of this bridge will be found most convenient.

A diagram of a Wheatstone bridge is shown at W in Fig. 33. The current employed is that furnished by a battery, h, usually composed of two cells. The battery, h, together with a key, k, for opening and closing the battery circuit are joined in series with each other and con-

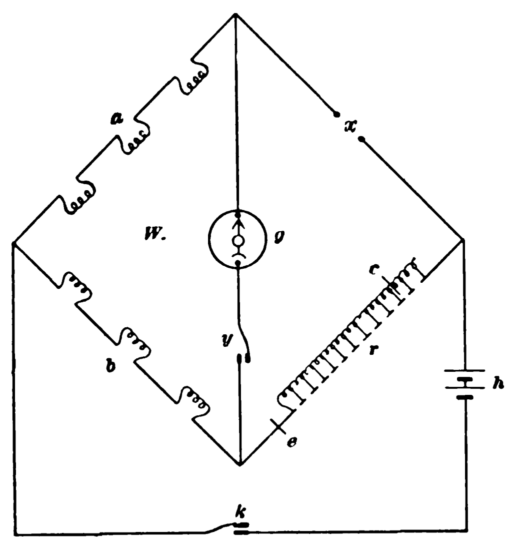


FIG. 33.

nected between the junction of a and b, and the junction of x and r. The parts a, b, x and r are called the arms of the bridge and represent resistances of which the three a, b and r have known values but x is the resistance it is desired to determine. The resistances a and b generally consist of three coils of 10, 100, and 1,000 ohms each and are known as the ratio arms of the bridge. The resistance, r, consists usually of about 16 coils ranging in value from 1 ohm to 4,000 ohms and is known as the adjustable resistance arm of the bridge. The resistance of each coil is, in every bridge, stamped immediately above the coil on the top of the bridge in full view of the tester. A galvanometer, g, and a key, y, for opening and closing the galvanometer circuit are joined in series between the junction of a and x, and the junction of b and r. In practice it is convenient to have the keys y and k close together so that they may be operated with the same hand. It is, however, advisable to close the battery key first, in order that the current through the arms of the bridge may become steady before the galvanometer is brought into circuit. This is particularly necessary when measuring the resistances of field magnet coils on account of the high inductance of the windings.

The resistance coils are formed of insulated german-silver wire and are wound non-inductively, that is, the wire is doubled before being coiled up, so that the magnetic field caused by one-half of the coil will be neutralized by the effect of the other half and thus exert no influence on the galvanometer. The resistance coils are brought into circuit at will by means of brass plugs, which when withdrawn from between the brass blocks to which the resistance coils are soldered, cause them to form a part of the arms of the bridge. Before commencing a test, it is necessary to have all the plugs in the respective holes short-circuiting the resistance coils. The plugs should fit firmly in position so as to reduce any error occurring in the measurements from contact resistances; for the same reason it is best to take advantage of the double terminals usually provided on the binding screws, by placing but one wire in each of the terminals. Another point worthy of mention is that of placing the wire to be connected, on that side of the screw so that when the binding nut is screwed down upon it, it will tend to draw the wire rather than push it; by so doing there will be less danger of the connection working loose and introducing undesirable resistance. It must also be remembered that a good electrical connection can be secured only when the contact surfaces are clean; it is therefore advisable to scrape the wires with a knife or with fine sandpaper before connecting them, and occasionally to clean the binding screws on the bridge.

The method of using the bridge for the measurement of resistance after being connected, as in Fig. 33, is as follows: The resistance whose value it is desired to determine is joined in circuit at x, and a certain known resistance, 100 ohms for example, is unplugged or introduced in each of the ratio arms a and b. In the arm, r, a resistance is unplugged which is as nearly equal in value to the unknown resistance x as can be guessed. The key, k, is then closed, following which the key y, is also closed. There should then be a deflection of the pointer in the galvanometer, g, and the direction of this deflection should be noted. If the value of the known resistance r introduced is too high the deflection will be in one direction, and if its value be too low the deflection will be in the opposite direction; a means is thus provided to guide one in determining the amount of resistance to introduce in r for any given case, the object being to so adjust it that there will be no deflection of the galvanometer pointer when both battery and galvanometer circuits are closed. When there is no deflection under the conditions mentioned, the arms of the bridge are said to be balanced, and the resistance x is then equal to the ratio of the resistances a to b multiplied by the resistance r, all resistances being expressed in

ohms. Expressed in a formula this becomes

$$x = \frac{a}{b} r.$$

When the resistance x is known to be low, as in the case of an armature winding, and it is desired to measure it within a fraction of an ohm unequal resistances should be used in the two ratio arms, that in the arm a being made the lower; on the other hand when the resistance x is known to be high, as in the case of insulation, the resistances in the ratio arms should also be made unequal but that in the arm a must be the higher. If a copy be made of the table here given which shows the best resistances to use in the ratio arms of the bridge for measuring different values in the x arm, and the copy be pasted on the bridge, no confusion need exist in making the various tests if some approximate idea be had of the unknown resistance. The values given in the table are intended for a bridge having a total adjustable resistance r of 1,110 ohms. If, however, the arm r has ten times this resistance then values of x ten times greater than those given in the table can be measured without altering the resistances in the ratio arms. The table is as follows:

Approximate value of x.	Resistance in a-arm.	Resistance in b-arm.
10 ohms or less.	1,000 ohms.	10 ohms.
110 " "	1,000 "	100 "
1,100 " "	1,000 "	1,000 "
11,000 " "	100 "	1,000 "
111,000 " "	10 "	1,000 "

In the operation of the Wheatstone bridge there are certain rules to be followed in addition to those already given, if the best results are to be obtained with the minimum amount of trouble. In Wheatstone bridges of standard form there will be found openings in the arm r at c and e which are marked inf. (infinite); under ordinary conditions these openings are bridged by brass plugs so that the circuit through them is normally closed. If the amount of resistance in the arm r is not found sufficient for making a given measurement, the plug at e is withdrawn and another box of resistance coils are connected to the binding posts provided on each side of the plug e. The test is then made in the same manner as before, the amount of additional resistance employed being of course taken into account in the value of r. In case the unknown resistance inserted at x is open-circuited, the plug at c becomes useful, for then a balance of the four arms of the bridge can only be obtained by removing this plug. Such being the case, the cause thereof is at once known. At times when the bridge is used merely as an adjustable resistance, the arm r only is employed, and these plugs may then be found useful as keys for connection and disconnection. In operating the galvanometer key it is advisable to tap it lightly until a balance is nearly obtained, else the galvanometer may be subjected to a strong current which will cause its needle to be deflected unnecessarily, and if the instrument is sensitive considerable time will be wasted in waiting for it to settle at rest. In addition to this, the needle is liable to be bent, and the resistance coils will become more or less heated, thereby increasing their resistance and introducing an error in the results if the current be left on too long or it be unnecessarily strong.

Measurements of insulation resistance may be made on the Wheatstone bridge in the manner previously described if the bridge be connected as in Fig. 33 and the insulation resistance be introduced in the x arm. Insulation resistances up 111,000 ohms may be measured on a Wheatstone bridge having in the arm r an adjustable resistance of 1,110 ohms, and insulation resistances up to 1,111,000 ohms may be measured if the adjustable resistance be 11,110 ohms. Beyond the value of 1,000,000 ohms or 1 megohm, however, it is usual to employ the equal deflection method for measuring insulation resistance.

The equal deflection method consists in comparing the galvanometer deflection produced by a current which passes through a known resistance with the deflection produced by the same current when passed through the unknown insulation resistance. The value of the latter is then equal to that of the known resistance multiplied by the ratio of the former deflection to the latter deflection. In making insulation resistance tests on generators, one of the lead wires should be connected to the armature or the field conductors as the case may be, and the other lead wire to the iron frame of the generator. In case the value of the insulation resistance between the armature winding and the field winding is desired, the two lead wires should be connected to these respective conductors. Care must be taken during the test that there be no other connections between the parts tested, and it is best to switch on the testing current about one minute before taking a measurement in order that the parts become well saturated. The testing current should be supplied at a pressure between 50 and 100 volts, and a shunt must be employed to vary the sensibility of the galvanometer. The galvanometer should preferably be of the D'Arsonval type, and the known resistance employed should have practically the same value as that of the insulation resistance undergoing test.

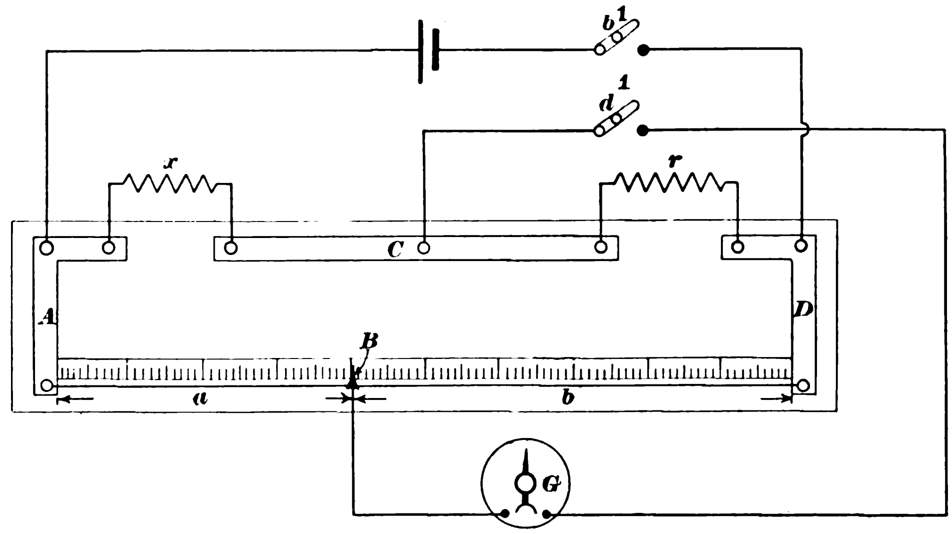

FIG. 34.

The ordinary magneto bell is sometimes used in a station to test the insulation of a machine. It is, however, a rough method at best only showing whether or not the insulation is up to a certain standard, which standard is that through which the magneto is designed to ring. This is usually between 10,000 and 30,000 ohms, so if the magneto be connected with one terminal to the winding of the generator, the other terminal to its frame, and the handle of the magneto rapidly revolved, it will be known if the bell rings that the insulation resistance is less than that amount; on the other hand if the bell does not ring, it will be known that the insulation resistance is greater than that amount. Inasmuch as the insulation resistance of a generator must usually be considerably greater than the figures previously mentioned, the magneto bell is seldom of much value in tests of this nature; it is, however, very convenient in testing the continuity of the circuit, that is, in ascertaining whether or not a cir-

cuit is complete. If it is complete, the bell will of course ring when the magneto is operated upon it, otherwise it will not. If a magneto bell be not at hand, a battery cell and an ordinary electric call bell may be used instead for testing the continuity of a circuit.

In addition to a resistance test of the insulation used on a generator, it should also be given a high potential test before the generator is placed in commission. For this purpose an alternating current of at least double the rated voltage of the generator should be used, the pressure being applied in succession between the armature winding and frame, between the field winding and frame, and between the shunt and series field windings. By means of an electrostatic voltmeter connected in the testing circuit, it is possible to measure the voltage applied and also to ascertain whether or not the insulation breaks down or becomes punctured thereby. If it does, the weak spot can usually be detected by a buzzing sound caused by the passage of a spark, and the defect must of course be remedied before the machine is put into service.

For the measurement of smaller resistances than those we have been considering, such for example as the resistance of contact between the brushes and commutator of a generator, which may perhaps be but a few hundredths or thousandths of an ohm, the slide wire bridge shown at A C D in Fig. 34 should be used. The bridge itself consists of three copper strips A, C and D, so arranged as to permit of the unknown resistance x being connected between A and C, and a known resistance r of approximately the same value as x being connected between C and D. Between the copper strips A and D, and resting upon a graduated scale, is stretched a german-silver or platinum-silver wire of considerable resistance so that there will be an appreciable fall of potential along it. Upon this wire slides a carriage B carrying some form of index for reading its position on the graduated scale. The carriage is joined in series with a low resistance, reflecting galvanometer G (provided with lamp, scale, and shunt) and a key d^1, and is electrically connected with the strip C. The current used in the test is obtained from a battery connected through a key b^1 to the strips A and D.

A comparison of the Wheatstone bridge in Fig. 33 with the slide wire bridge in Fig. 34 will show that the latter is but a modification of the former, and to render the comparison less difficult the corresponding resistance arms of the two bridges are lettered the same. The only difference here is that instead of varying the known resistance r, this resistance is maintained constant, and the resistances in the ratio arms a and b are varied by moving the carriage B along the silver wire beneath it until a balance is obtained; that is, by adding resistance to one of the ratio arms and subtracting it from the other ratio arm, a point is finally reached where no deflection occurs in the galvanometer G upon closing the battery and the galvanometer circuits. Under these conditions the unknown resistance

$$x = \frac{a}{b} r.$$

In this formula, r equals the value of the unknown resistance, and a and b are the respective distances as measured on the graduated scale between the index on the carriage B and the copper strips A and D. Theoretically, a represents the resistance of the silver wire between B and A, and b the resistance of the silver wire between B and D, but since the wire is of uniform area and composition its resistance is uniform, and so the ratio of the resistances is equal to the ratio of the lengths. In practice, the scale is graduated into 1,000 equal parts and it being therefore easy to read the lengths a and b, they are always used in preference to the corresponding resistances.

As in testing with the Wheatstone bridge, the key b^1 in the battery circuit of the slide wire bridge should be closed a few seconds before the key d^1 in the galvanometer circuit, for the reason previously stated. It is also necessary where particularly accurate results are desired, to interchange the positions on the bridge of the known and unknown resistances and take a second reading of the index on the carriage; the two values found for x should then be averaged. The result thus obtained will be practically free from errors due to the introduction of contact resistances at the extremities of the silver wire. In tests meriting the elimination of contact resistances, the position of the galvanometer should be considered; it should be placed at such a distance from the resistance coils that any magnetic effect developed by the latter will not influence the deflection in the galvanometer. A convenient method of testing for such a disturbance consists in disconnecting the galvanometer leads and watching for a deflection when the testing current is alternately applied to the rest of the apparatus.

The proper time for measuring armature or field resistances is immediately after shutting down the generator from a full load run, for then these windings are warm and consequently of a higher resistance than when they are cold. The results obtained at that time will therefore represent the actual working values which are usually those most desirable to obtain.

ELECTROLYTIC SEPARATION OF METALS.

(From our London Correspondent.)

Mr. M. Hollard contributed to the February meeting of the Faraday Society (London) a paper on "Some Applications of the Theory of Electrolysis to the Separation of Metals from One Another." He explained that the only principle hitherto involved in electrolytic separation has been based on the method of successive potentials, each metal depositing at the potential proper to that metal. In practice this principle has only been applied to metals (copper and silver, silver and bismuth, mercury and bismuth) whose polarization potentials are lower than that of hydrogen. Metals whose polarization potentials are higher, cannot be separated by gradual increase of the EMF. on account of the extremely small fraction of the current then used to precipitate the metal, hydrogen ions carrying most of current. Mr. Hollard therefore made use of three other applications of the theory of electrolysis as follows:

I.—Reduction of the Resistance of the Bath by Suppressing the Formation of the Gas at the Anode.—The current may thus be increased in two ways. (1) By suppressing the liberation of oxygen at the anode. To effect this a reducing agent such as sulphurous acid may be introduced. The same potential will then greatly augment the current and hasten precipitation. The method has been successfully applied to separate nickel from zinc. (2) By the use of soluble anodes. The anode must replace in the solution the metal that is to be separated, and that only, and it must be immersed in the solution of an indifferent salt, a membrane separating the anolyte and catholyte. Obviously an external source of electricity is unnecessary. The nickel zinc separation is again given as an example, the operation being described in detail. In this case there is a limit to the relative quantities of zinc and nickel that can be separated. For by Nernst's formula

$$e = \frac{k}{v} \log \frac{P}{C} - \frac{k}{v} \log \frac{P^1}{C^1}$$

where e is the EMF. between the metals, k a constant for a definite temperature, v and v^1 the valencies, and C and C^1, the

concentrations of the precipitating and precipitated metals. When the concentration C of the zinc in the inner cell increases, e will diminish. There must not, therefore, be too much nickel to deposit. The phenomenon is complicated by secondary reactions which must be taken into account in the cases of other separations, such as concentration EMF.'s, increase of EMF. due to local action, and migration. These were discussed fully in the paper.

II.—Influence of the Nature of the Cathode.—By suitably choosing the metal for the cathode, the liberation of hydrogen may be completely avoided, and the conductivity may be so much increased that the separation of the metals becomes possible. The division of metals into two groups which can and cannot be deposited from strongly acid solution, has for its basis the position occupied by hydrogen in the polarization potentials of the metals. But this, as Caspari has shown, varies with the metal of the cathode. Hence by suitably altering that metal, metals can be made to pass from one group to the other, and thus separations, impossible with a platinum cathode, may be effected. The separation of zinc and cadmium (impossible on a platinum cathode) is given as an example. Platinum gauze, covered electrolytically with tin and cadmium, forms the cathode.

III.—Formation of Complex Salts.—Metals may be prevented from precipitating by causing them to form complex salts, which dissociate to give not the metallic ions, but complex ions containing the metal. As an example, the separation of antimony and tin in a solution of sodium hydrogen and sulphide was described.

A FEW NOTES ON THE STEAM TURBINE.*

BY HON. G. L. PARSONS.

The early turbines were governed by a lantern type of throttle valve worked by the movement of a leather diaphragm, which the suction of a fan on the shaft tended to close against a spring. The admission of air to the diaphragm was controlled by an electrical governor. On the top of the magnet yoke there was a small iron bar pivoted on a vertical spindle and carefully balanced. This was moved round by the alteration of the magnet yoke against a spiral spring. A double finger or arm was keyed on the same vertical spindle; the end of each finger was flat, and when opposite to the inlet of the air-pipe, closed it. The spiral spring was so adjusted by a movable head that the greater the voltage the more was the air inlet closed by one of the fingers. When the inlet was open the air rushed along the pipe and partially neutralized the suction of the fan, allowed the diaphragm to extend, and thus opened the throttle valve. If the dynamo got demagnetized the needle turned the other way, and the safety finger closed the air inlet and thus cut off steam. This type of governor was very sensitive, and kept the voltage steady within 1 per cent. The steam consumption of a 32 kw. plant of this type running non-condensing was about 48 lbs. per electrical horse-power hour with a boiler pressure of 61 lbs., and about 42 lbs. per electrical horse-power hour with a boiler pressure of 92 lbs.

In 1899, owing to temporary loss of patents, the radial-flow type of turbine had to be adopted. This consisted of a series of fixed annular disks with rings of blades, between which another series of disks keyed to a shaft rotated. The guide blades were secured to the faces of the stationary disks, and nearly touched the rotating disks, while the moving blades, nearly touched the fixed disks. The steam passed outwards through the successive rings of blades, then inwards along the back of the first moving disk, and again outwards through the next ring of blades until it finally reached the exhaust. In 1892 this type of turbine was first tried condensing with a vacuum of 27 inches. With slightly superheated steam at a pressure of 100 lbs. the consumption at the normal full load of 100 kw, was 27 lbs. per kilowatt hour.

In 1894, however, the parallel flow-type was again adopted with considerable improvements. The turbine was made single-ended, with the steam passing in one direction only, the second series of rings being replaced by three rotating pistons, or dummies, by which the end pressure of the steam along the shaft was balanced. Each of the pistons corresponded in size to the part of the turbine it balanced, and to which it was connected by a pipe. Grooves were turned in these pistons, between which the corresponding fixed collars of the cylinder projected, and, being almost in contact, reduced the leakage of steam to less than 2 per cent.; the amount of clearance could also be regulated by the thrust bearing at the end of the turbine shaft.

The governor can be of the mechanical type, which keeps the speed constant, or of the electrical solenoid type, which maintains a constant pressure at the terminals of the dynamo by raising the speed of the turbine to meet the fall in voltage due to the increase of the load. The electrical governor is now seldom fitted except on the smaller continuous current plants. A small pump supplies oil under pressure to all the bearings, the oil being then returned to the tank to be used over and over again, resulting in a great saving as compared with reciprocating engines. Inside the cylinder itself no lubrication is required, since no parts are touching; the two end packing glands being of similar construction to the balancing pistons, also run clear, hence no oil can possibly find its way into the exhaust. Turbines are running in breweries and chemical works, where the exhaust is led straight into the vats or liquids which require to be heated, and at Heaton part of the turbine exhaust steam is especially condensed to be used as distilled water for delicate chemical processes. The cost of oil for a large turbine works out at about 0.002d. per kilowatt hour. The single-cylinder type of turbine has again been adopted for the large as well as for the smaller sizes, being found cheaper as well as more efficient, besides requiring a shorter engine room. Plants up to 10,000 I.H.P. are now being constructed with a single cylinder. As a high vacuum is most important for obtaining the best results in steam economy, ample space is allowed at the end of the turbine for the exhaust steam, and the condenser is generally placed in a pit straight under the turbine, so that the drop in vacuum may be as small as possible between the machine and the condenser, while the length of piping required is greatly reduced. The following table shows the effect of variation of vacuum on the consumption of steam in the case of a 1,500 kw. set. For the smaller sizes the variation is not so marked:

Vacuum bar = 30 in. Inches.	Difference in steam consumption per 1 in. of vacuum. Per cent.
29	6
28	5
27	4
26	3½
24	3
22	2¼
16	2

As regards the cost of obtaining these high vacua, a little investigation will show that the extra power required to maintain a higher vacuum in a given condenser (and the cooling surface need not be larger than usual) is very small in comparison with the saving of steam in the main turbine with a good vacuum. Three sets of 300 kw. each have just been completed for the Corporation of Derby. They run at 3,000 revs. per min., and

*Abstract of a paper read before the Newcastle (Eng.) Local Section of the Institution of Electrical Engineers, March 21, 1904.

are intended to supply current for traction and lighting. Curves were taken on a Horn tachograph showing the variation of speed when the main circuit was made and broken on a load of 350 kw. The temporary variation did not exceed $4\frac{1}{2}$ per cent. and the permanent $2\frac{1}{2}$ per cent. The dynamo was tested by throwing 350 kw. off and on when running both as a shunt machine and as a compound, no movement being found necessary for the brushes, which were of brass wire. The following table shows the variation of voltage under different conditions:

	Kilowatts.	Voltage.	Speed.
Compounding in use ..	0	505	3,075
" "	336	565	3,000
Shunt only	300	500	3,000
	0	543	3,075
	0	520	3,000
(Constant excitation)...	0	518	3,000

STEAM TURBINES FOR BOSTON NAVY YARD.

An interesting departure in engineering practice by the authorities of the United States Navy, Department of Yards and Docks, is marked by the introduction of Westinghouse-Parsons steam turbines for furnishing power for lighting the buildings and yards, and power for operating dry dock pumps and miscellaneous machinery.

The initial installation of this character is in process of construction at the Charlestown Navy Yard, Boston, Mass., and for the present one Westinghouse-Parsons turbine generating unit of 750 kw. capacity will be placed in service. This turbine will be of the new short-barreled type and is now under construction at Pittsburg. Worthington surface condensers will be employed, using salt water for circulation. The condensers will be located between the foundations, which consist of concrete piers. A running vacuum of 28 inches will be secured through the aid of a dry air pump. Steam will be furnished at 150 lbs. pressure by Babcock & Wilcox boilers in units of 350 hp., equipped with Roney mechanical stokers. Coil superheaters in the boiler settings will furnish to the turbine a superheat of about 100 degrees F. The boiler house will be equipped with a complete outfit of coal and ash handling machinery.

The present power plant is the outcome of an appropriation made in 1898 by Congress for a dry dock and pumping plant to be located at the Charlestown Navy Yard, the new plans for a dry dock equipment providing for a power plant located near the outer end of the new dock with piping connections to both old and new docks so that the one pumping plant would be able to handle them simultaneously or separately. During the period of construction of the new dock the Department of Yards and Docks at this Navy Yard underwent considerable enlargement necessitating an immediate increase in an electrical generating equipment for supplying light and power to buildings and departments.

In view of this situation, it was decided to supersede the dock pumping plant, originally provided for, by a central lighting, power and heating plant for the entire department, although retaining the dry dock pumping equipment, which will now be electrically driven from the central station. It is also intended to supply from this plant electric light and power to the vessels docking which do not happen to be under steam. The power system as now under construction is, therefore, considerably more comprehensive than originally laid out.

The turbine plant will supply three-phase alternating current at 2,300 volts, this voltage being used for general distribution and for direct use in larger motors, while for lighting, lower voltage will be provided by transformation. The turbine generator will be served by a $37\frac{1}{2}$ kw. compound exciter unit.

AMERICAN STREET RAILWAY ASSOCIATION

We have received the following communication from Secretary Penington:

"The 23d Annual Convention of the American Street Railway Association will be held in Recital Hall, Festival Hall Building, World's Fair Grounds, St. Louis, Mo., Wednesday and Thursday, October 12 and 13. One session each day, 10 A.M. to 1 P.M. The Mechanical and Accountants' Associations will meet the same week at the same place, so all members will have an opportunity of attending all the conventions and visit the exposition at the same time. No exhibits will be displayed by this association this year. The headquarters of the association will be at the Southern Hotel. A limited number of rooms will be reserved for us at the downtown hotels, if applied for before June 1. The rates are as follows: Southern Hotel, $10 to $15 per day per room with bath, American plan; Planters Hotel, $10 per day per room with bath, European plan; Jefferson Hotel, $10 to $15 per day per room with bath, European plan; St. Nicholas Hotel, $7 to $10 per day per room with bath, European plan; Lindell Hotel, $5 per day per room with bath, European plan.

"Rooms can be occupied by three persons if desired at same price, the charge being for the room whether occupied by one, two or three persons. It must be understood to reserve rooms in these hotels, that they must be paid for from October 8 to the end of the convention, two days in advance of convention week, and whatever revenue is received by the hotels for these rooms during the 8th and 9th will be rebated to you.

"Wednesday, October 12, has been set apart as 'Street Railway Day' and special attractions of some kind will be furnished by the exposition authorities. The banquet will be held Thursday evening, October 13.

"Papers will be presented that will interest all members.

"The following resolution was directed to be sent to all members, viz.: 'The secretary is directed to request the chief officers of the different companies to notify delegates and heads of departments attending the convention for the companies they represent that they will be expected to attend each session and take part in the discussion, that hereafter at each session of the convention the roll of delegates will be called at the time meeting is called to order, and that the roll call will be published in the minutes of the meeting.'"

INTERNATIONAL ELECTRICAL CONGRESS.

We are informed that the following papers are promised for Section A—the section on "Theory" of the International Electrical Congress—of which Prof. E. L. Nichols is chairman and Prof. H. T. Barnes secretary:

FOREIGN.

Prof. Paul Drude—"Metallic Conduction."

Prof. W. Jaeger—"Electrical Standards."

Sir Oliver Lodge, F.R.S.—"Ions."

Prof. H. Nagaoka—"Magneto-Striction."

Dr. J. J. Thomson, F. R. S.—Subject to be announced.

Prof. J. S. Townsend, F.R.S.—"The Theory of Ionization by Collision."

Mons. J. Violle—"Secondary Standards of Light."

C. T. R. Wilson, F.R.S.—"Condensation Nuclei."

Prof. P. Zeeman—"Magneto-Optics."

AMERICAN.

Dr. Louis A. Bauer—"The State of Our Knowledge Regarding the Earth's Magnetism."

Dr. Carl Barus—"Atmospheric Nuclei."

Prof. H. T. Barnes—"The Mechanical Equivalent of Heat as Measured by Electrical Means."

Prof. D. B. Brace—"Magneto-Optics."

Prof. H. S. Carhart and G. W. Patterson, Jr., Ph.D.—"The Absolute Value of the Electromotive Force of the Clark and Weston Cells."

Prof. C. D. Child—"The Electric Arc."

Dr. K. E. Guthe—"Coherer Action."

Prof. E. P. Lewis—"Electrical Discharges in Gases."

Prof. L. T. More—"Electrostriction."

Prof. E. F. Nichols—"The Unobtained Wave Lengths between the Longest Thermal and the Shortest Electric Waves yet Measured."

Prof. E. L. Nichols—"Standards of Light."

Harold Pender, Ph. D.—"Magnetic Effect of Moving Charges."

Dr. M. I. Pupin—"Electrical Theory."

Dr. Edward B. Rosa—"Alternating Current Measurements."

Prof. E. Rutherford—"Radioactive Change."

Prof. J. C. McLennan—"Radioactivity of the Atmosphere."

Prof. J. Trowbridge—"Electrical Discharge in Gases."

Prof. A. G. Webster—"Electrical Theory."

It is evident from the above list that a very fine programme has been secured by the officers of Section A.

A meeting of the Congress Committee of Organization is scheduled for April 23, at 1:30 P.M., at the offices of the American Institute of Electrical Engineers, 95 Liberty street, New York City.

Acceptances of membership in the Congress number over 1,300 up to the present time, and 150 papers have been promised in all.

The following societies have all promised to hold conventions in St. Louis during the Congress week, and to hold conventions with one or more sections of the Congress: American Institute of Electrical Engineers, American Physical Society, American Electrochemical Society, American Electro-Therapeutic Association and the International Association of Municipal Electricians.

The British Institution of Electrical Engineers has also arranged to co-operate under some plan, the details of which have not yet been determined.

The following bodies have promised to co-operate by sending delegates: Societe Internationale des Electriciens, National Electric Light Association, Association of Edison Illuminating Companies and various other societies.

American Institute of Electrical Engineers.

The 186th meeting of the American Institute of Electrical Engineers will be held at the Chapter Room, Carnegie Hall, 154 West 57th street, Friday, April 22, at 8:15 P. M. The following papers will be presented: "The Mechanical Construction of Revolving Field Alternators," by David B. Rushmore, assistant electrician of Stanley Electric Manufacturing Company, Pittsfield, Mass.; "Contribution to the Theory of the Regulation of Alternators," by H. M. Hobart and Franklin Punga, Electrical Engineers, London, England.

American Electrochemical Society's Officers.

The Electrochemical Society brought its Washington convention to a close by electing the following officers: Prof. Henry S. Carhart, of Michigan, president, C. J. Reed, of Pennsylvania; C. F. Burgess, of Wisconsin, and E. J. Acheson, of Niagara Falls, vice-presidents; and Dr. W. H. Walker, of Boston, Mass.; E. C. Acker, of Niagara Falls, and Edward Weston, of Newark, N. J., managers. P. G. Salom, of Philadelphia, was reelected treasurer.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 12, 1904.

Electric Railways and Appliances.

756,859. Trolley-Catcher. Montgomery H. Johnson, Utica, N. Y. Filed July 15, 1903.

756,870. Electric-Railway Switch. Melbourne A. Marks, Jr., Brookline, Mass. Filed Feb. 4, 1903.

756,957. Electric Safety System for Railways. Jacob Hanna and Charles S. Gilman, Rivera, Cal. Filed May 7, 1902.

756,980. Electric Railway. William B. Potter, Schenectady, N. Y., assignor to the General Electric Company. Filed July 5, 1902.

757,107. Safety Device for Electric-Railway Systems. George Gibbs, New York City. Filed Aug. 26, 1903.

757,125. Electrical Railway Danger-Signal. William E. Karns, Parkers Landing, Pa. Filed Nov. 12, 1903.

757,138. Third Rail for Electric Railways. Patrick T. McGowan, Avoca, Pa. Filed Dec. 22, 1903.

757,264. Electric Railway. Davis J. Cable, Lima, O. Filed March 11, 1903.

757,346. Electric Signal for Railways. William B. Ramsay, Hickory, N. C. Filed May 29, 1903.

Electric Lights and Appliances

756,976. Portable Testing and Comparing Instrument for Electric Incandescent Lamps. Albert McCandlish, George Lane, Bredbury, Eng. Filed June 26, 1903.

757,007. Lamp-Terminal. Howard I. Wood and Ralph C. Robinson, Schenectady, N. Y., assignors to the General Electric Company. Filed July 26, 1902.

757,079. Electric-Arc Lamp. James J. Wood, Fort Wayne, Ind. Filed Sept. 4, 1903.

757,314. Electric-Lamp Guard. Jonas Kaufman, Newcastle, Pa. Filed Aug. 1, 1903.

757,364. Combined Lighting and Alarm Device. John Thorsen, Chicago, Ill. Filed Sept. 24, 1903.

Electrical Machinery and Apparatus

756,846. Electrogoniometer. Alexandre Grammont, Pont de Cherny, France. Filed July 10, 1902.

756,960. Rotary-Coverter System. Edward M. Hewlett, Schenectady, N. Y., assignor to the General Electric Company. Filed July 24, 1899.

756,979. Handle for Rotary Snap Electric Switches. Charles G. Perkins, Hartford, Conn. Filed Oct. 29, 1903.

756,991. Electric Condenser. Matthew O. Troy, Lynn, Mass., assignor to the General Electric Company. Filed July 19, 1902.

757,000. Demand-Meter. Roger S. White, Philadelphia, Pa., assignor to the General Electric Company. Filed Aug. 15, 1903.

757,019. System of Motor Control. Frank L. Butler, Schenectady, N.Y., assignor to the General Electric Company. Filed Sept. 13, 1902.

757,064. Electric Igniter for Gas-Engines. Harry J. Smith, Buffalo, N. Y., assignor to the Alberger Company, same place. Filed Aug. 3, 1901

757,261. Power-Transmission Gear. William O. Brown, Chicago, Ill., assignor to the National Hydrocarbon Car Company, same place. Filed May 2, 1903.

757,302. Electric-Current Regulator. Newton Harrison, New York City, assignor of one-half to William Henry Laird, same place. Filed April 21, 1903.

757,357. Dynamo Brush-Holder. William Slee, St. Louis, Mo. Filed Sept. 8, 1903.

757,379. Frictional Power-Transmitting Device. William O. Worth and John D. Worth, Chicago, Ill. Filed Dec. 30, 1903.

757,394. Means for Variably Operating and Controlling Electric Motors. Rudolf Eickemeyer, Yonkers, N. Y.; Rudolf Eickemeyer, Jr., Carl Eickemeyer and Mary T. Eickemeyer executors of said Rudolf Eickemeyer, deceased. Filed June 2, 1893.

757,405-757,406. Booster Apparatus. Lamar Lyndon, New York City, assignor to the National Battery Company, Jersey City, N. J., and Buffalo, N. Y. Filed Aug. 21, 1902.

Telephones and Telephone Apparatus

756,813. Long Distance Telephone System. Michael Beck, Minneapolis, Minn. Filed Nov. 12, 1900.

756,824. Telephone Selecting Device. Lawrence E. Brock, Celina, O. Filed May 13, 1902.

757,031. Semi-Automatic Telephone Exchange. Ernest A. Faller, New York City, assignor of one-half to James W. Chisholm, same place. Filed July 1, 1903.

757,257. Telephone Receiver Support. James A. Brown, Warren, O. Filed Oct. 8, 1903.

757,340. Telephone Support. Howard H. Oothoudt and William F. Stahl, Toledo, O. Filed Jan. 29, 1904.

Miscellaneous.

756,850. Electrical Wire Station. William E. Hamilton, Columbus, O. Filed June 18, 1903.

756,857. Electrician's Tool. Herbert H. Hutchings, Chester, Pa. Filed June 19, 1903.

756,864. Electric Lock. Jay Livingston, St. Louis, Mo. Filed May 22, 1903.

756,891. Rotary Electric Tube Furnace. Henry N. Potter, New Rochelle, N. Y., assignor to George Westinghouse, Pittsburg, Pa. Filed Nov. 21, 1901.

756,935. Perforating Glass Bulbs. William R. Burrows, Newark, N. J., assignor to the General Electric Company. Filed March 19, 1902.

756,937. Synchronizing Device. Nathan E. Church, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 27, 1902.

756,941. Spark Gap for Roentgen-Ray Apparatus. John T. H. Dempster, Schenectady, N. Y., assignor to the General Electric Company. Filed June 18, 1898.

756,954. Magnet Coil Spool. Henry Geisenhoner, Schenetady, N. Y., assignor to the General Electric Company. Filed Sept. 13, 1902.

756,966. Panel Board for Electric Distribution. George H. Jones, Chicago, Ill. Filed Nov. 20, 1903.

757,056. Means for Protecting Electrical Measuring Instruments. Maurice C. Rypinski, Schenectady, N. Y., assignor to the General Electric Company. Filed July 25, 1901.

757,164. Battery Cell. Emerson Whitman, Lynn, Mass. Filed July 2, 1903.

757,210. Apparatus for Making Grids for Secondary Battery Plates. Albert F. Madden, Newark, N. J., assignor, by mesne assignments, to the Electric Storage Battery Company, Philadelphia, Pa. Filed April 11, 1903.

757,271. Electromechanical Gong. Frederick W. Cole, Newton, Mass., assignor to the United States Fire & Police Telegraph Company, Boston, Mass. Filed Oct. 4, 1902.

757,341. Relay Magnet. William Palmer, Jr., Rincon, N. Mex. Filed June 14, 1902.

757,355. Galvanic Battery. Charles B. Schoenmehl, Waterbury, Conn., assignor to the Waterbury Battery Company. Filed Nov. 22, 1899.

757,388. Lightning Arrester. Garrison Babcock, Chicago, Ill. Filed Sept. 20, 1902.

757,396. Storage Battery Grid. George W. Frost, Columbus, O. Filed Feb. 9, 1904.

757,422. Dry Battery. Alfred F. Swan, Bayonne, N. J., and Allen W. Rose, New York City, assignors of one-half to the Patent Development Company of America. Filed July 22, 1903.

THE TELEPHONE WORLD.

Eastern New York Independent Companies United.

The Saratoga Telegraph & Telephone Company has consolidated with the Rensselaer Telephone & Telegraph Company of Troy and the Union Telephone Company of Glens Falls. The three systems are to be acquired by the Commercial Union Telephone Company.

New Company for Colorado.

The Wray Telephone Company of Colorado will endeavor to establish telephone communication between Lincoln, Omaha, Neb., and Denver, by means of affiliation with the Colorado Telephone Company and the Nebraska Telephone Company. The intention, as announced by M. H. Spere, a director of the Wray Company, is to build a line connecting Brush, Col., with Culbertson, Neb. The company already has a connection with the Colorado company at Brush, and an arrangement for exchange of business. A similar contract will be asked of the Nebraska company. This will connect Denver and other Colorado towns with the rest of the world as by means of the Lincoln and Omaha connection with Kansas City and Chicago it will be possible to talk to Atlantic coast towns. The company already has several exchanges in operation in Nebraska.

The Automatic Electric Company of Chicago, has installed an experimental set of telephone instruments at Greensboro, N. C., which are working with wonderful precision and alertness, without the presence of any one at all at "central." The connection is automatic, instaneous, and if the line is busy, the fact is indicated by an immediate "buzz" from the machinery at central. The citizens' committee, who have in charge the investigations into the establishment of an Independent system in Greensboro is making a very careful examination of this new improvement in the telephone world, and unless the present friction or war with the Bell Company is adjusted soon the automatic service will be used in the new system.

The Home Telephone Company of Lead, S. D., which has recently taken over the property and property rights of the old Harrison Telephone Company, has three crews in the field repairing and improving its system. The lines connecting Lead with adjoining towns and communities are receiving new poles and wires, and new plants are to be introduced in Lead and Deadwood for the central stations.

The telephone line connecting Hiattville, Kan., with Fort Scott, has been completed and is now in operation. The line is about 25 miles long and has connection with Hepler, Godfrey and a large number of farm residences between the towns named.

Work on the new telephone line from Landisburg to Bloomfield, Pa., is progressing, the poles having been placed along the line preparatory to setting and stringing the wire.

Prominent business men of Iowa City, Ia., are interested in a new telephone company, with a capital of $100,000, that has entered the Johnson County field, and an active rate war is expected.

Extension of Independent Telephones in Nebraska.

A force of men in the employ of the Home Telephone Company are working in the extreme southern part of Sarpy County extending that company's line. There are now 450 telephones in operation throughout that vicinity, including the 175 used in Papillion. Many new orders are being filled as fast as possible and by summer there will be 600 telephones in use throughout Sarpy County. The business is steadily increasing. Arrangements have been made for long distance connection and patrons of the Home Telephone Company are given Lincoln service.

At the recent annual meeting of the Ithaca, N. Y., Telephone Company the directors elected as officers: B. G. Hubbell, president; M. VanCleef, vice-president; H. C. Hinckley, treasurer; Judge Charles H. Blood, secretary. The executive committee is composed of Charles H. Blood, B. G. Hubbell and William T. Morris.

The Potato Belt Telephone Company will operate telephone lines in Anoka, Isanti and Chisago Counties, Minn., with a capital stock of $20,000. Charles E. Burch is president; Roland J. Dyer, vice-president; Marcia A. Mitchell, secretary. With Elmer E. Davis, George L. Sylvester and Samuel F. Cooper, the officers constitute the first board of directors.

The Citizens' Telephone Company in Clinton, Ind., is unable to supply the demand for telephones. Two new lines recently entered that city, and two now are being put up in the western part of the township near Jacksonville, and Scotts.

Owing to the constantly increasing demand of the farmers for telephone connections a new rural line is to run south from Milford, Mich., along the New Hudson road for the accommodation of residents of that vicinity.

The Preble County, O., Telephone Company has been incorporated by John C. Stover, J. E. Flora, A. M. Fudge, J. S. Steward and others. Its capital stock is $25,000.

The Medora telephone line is to be extended from Medora to Inman, Kan., a distance of eight miles, giving Inman its first Independent telephone service.

The Allen County, Ky., Home Telephone Company, with a capital of $2,500, filed articles of incorporation in the office of the Secretary of State a short time ago.

A new concern, known as the Eau Galle, Wis., Telephone Company, has been incorporated by C. G. Billings, William Stoops and F H. Thines.

In March the Chicago Telephone Company installed 1,580 new telephones, making the number in service 105,948.

The Lebanon Telephone Company is rushing the extension of its line from Whitehouse to North Branch, N. J., as rapidly as possible.

The Northville, Mich., Telephone Company is rushed with orders for new telephones.

Telephone Expansion in Ohio.

The Winona Central Telephone Company has begun the extension of its system to the village of Dungannon, where an exchange will be installed with 40 or 50 telephones to begin with. The main line will be extended from Dungannon to Lisbon, which will give the Winona company two trunk lines to the county seat.

The system at Winona has about 200 instruments in operation at the present time, extending over a wide territory. It has connections with most of the Independent systems in Northern Columbiana County, and with the Columbiana County Telephone system.

Within a short time an additional trunk line will be strung between Winona and Salem, which is badly needed; as the traffic is very heavy between those two places. With two lines to Lisbon and two to Salem the company can give much better service.

The Central Ohio Telephone Company of Centerburg, Knox County, has been incorporated by Charles L. Bishop, T. P. Sylvan, E. E. McGuire, J. E. Litzenburg and G. N. Jackson, and will be operated on $10,000 capital stock. It will operate a telephone exchange in Knox County, and pass through Morrow, Licking and Delaware Counties.

At a recent meeting of the executive committee of the Retail Druggists' Association at Kansas City, Mo., it was decided to make an active canvass among the druggists and physicians to abolish the Bell service and substitute the Home.

At a meeting of the village council of Somerville, O., the Hamilton Home Telephone Company was granted a franchise to construct, maintain and operate a telephone system in Somerville. The lines are now being built from Collinsville to Somerville.

The annual election of the Farmers & Merchants' Telephone Company was lately held at Alma, Neb. R. L. Keester was chosen president and general manager. The gross earnings for the year were $2,100 and there are 250 telephones in operation.

The Cairo, O., Telephone Company has elected officers as follows: President, Harry McKinney; vice-president, F. Haines; secretary, John Boucher; treasurer, J. W. Stigall.

The directors of the Farmers' Telephone Company of Hardin, Ill., have perfected plans to extend the company's line from this place to Meppen.

Telephone Incorporations.

The Pennington Telephone Company, Jersey City, N. J. Capital stock, $5,000. Incorporators: William H. Bogart, Jerry J. Croley, and Jos. F. Harris.

The Egg Harbor City Telephone Company, Egg Harbor City, N. J. Capital stock, $3,000. Incorporators: Lorenz Krein, William G. Stockman, George W. Otto and Charles Oberender.

The Telephone Electric Toll Box Company, Trenton, N. J.—to manufacture telephone boxes and apparatus. Capital stock, $125,000 Incorporators: Charles L. Walton, Romeo B. Hazlett and Eli H. Chandler.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Ashland, O.—The council is contemplating putting the question of electric lighting to a vote of the people soon, instead of specifications being wanted, as stated in the issue of ELECTRICITY of March 30.

Belchertown, Mass.—The Amherst Electric Light Company is looking over the ground here with a view to establishing an electric light plant.

Camp Point, Ill.—W. A. Berrian has under consideration the matter of installing an electric light plant here.

Charleston, Mo.—An electric light plant and ice factory may be erected by L. W. J. Danforth.

Chicago, Ill.—This city has granted a 10-year franchise to the University of Chicago, giving it permission to sell electricity for lighting The franchise gives the university the right to use parts of La Salle street and Fifth avenue. Ten per cent. compensation was required.

Edina, Mo.—Mr. Wilson, owner of the Edina electric light plant, has asked the council to grant him a 10-year franchise. He desires to make some extensive improvements to the plant.

Emporia, Kan.—Frederick Bruggemann, of Denver, Col., will probably ask for an electric light plant franchise.

Fall Creek, Wis.—The proposition to have electric lights here is being discussed.

Fond du Lac, Wis.—The council has accepted the bid of the Citizens' Light, Heat & Power Company of Milwaukee for a franchise for a new electric lighting and power plant.

Glastonbury, Conn.—Plans for the development of a combined electric light and water power plant on Roaring Brook have been nearly completed by the Glastonbury Power Company.

Greensboro, Ga.—A franchise for electric lights was lately granted T. B. Rice, of this place, and R. L. West, of Atlanta, and their associates.

Hailey, Ida.—The electric light plant here has been sold to the Idaho Electric Supply Company, with Leo Cramer as president. New machinery may be installed.

Hazelhurst, Ga.—A stock company is being organized here for an electric light plant and waterworks. The cost for both will not exceed $1,500. The power for the electric lights will probably be furnished by the Hazelhurst Manufacturing Company.

Kenmare, N. D.—A new electric light and power plant is to be erected here soon.

Mason City, Ia.—The citizens have voted for an electric light franchise.

Melvin, Ill.—The village council has granted a 20-year electric light and heating franchise to E. E. Sailor, of Cullom.

Nassau, N.Y.—The Nassau Electric Light & Power Company is in the market for a 3,000 kw. generating set to be installed in its new station at Hempstead Harbor, L. I. C. O. Mailloux, electrical engineeer, of No. 76 William street, New York City, has been retained by the company in a consulting capacity.

New Iberia, La.—The city council is making provision for a system of street lighting.

Ocala, Fla.—Col. W. N. Camp, of this city, has made a proposition to the council for the purchase of the electric light plant and all appurtenances. Col. Camp has a project to utilize the waters of the Withlacoochee River, and agrees to furnish the city with at least 1,000 hp.

O'Fallon, Ill.—The citizens are to vote on the question of purchasing the electric light plant here.

Oklahoma, Okla.—The American Electric Light & Power Company has applied for a franchise to construct an electric light plant.

Ossian, Ia.—The citizens will vote on the proposition to issue $5,000 in bonds for lighting purposes.

Pasco, Wash,—Electric lighting of this town is considered. A dynamo may be installed at the Northern Pacific Company's engine house for that purpose.

Prairie View, Tex.—An electric light and power plant will be installed at the State Normal School here. Address Prof. Brown, College Station.

Sedalia, Mo.—The city council is figuring on submitting a proposition to bond the city for money to operate an electric light plant.

Walden, Col.—An electric light and a water plant will be installed here this summer.

Winfield, Kan.—At a recent city election the people voted in favor of issuing $134,000 bonds for the installation of an electric light plant and waterworks system.

STREET RAILWAYS.

Albion, N. Y.—Machinery tools and material are on hand to commence the work of extending east and west the Albion Electric Railway.

Arcola, Ill.—The Eastern Illinois Traction Company has been granted a 50-year franchise to operate an electric line over certain streets in this city.

Buffalo, Ill.—The Illinois Central Traction Company has been granted the right to extend its line through here.

Charlotte, Mich,—Some time ago E. F. Pangburn and A. J. White, of the Michigan Central Traction Company, were denied a franchise by the old council of this city, in spite of a $1,000 check tendered as a forfeit for alleged "lack of faith" in their ability to finance the road. The new council is quite likely now to give the Michigan Central Traction Company a franchise, in which case the Lansing-Battle Creek Electric Road will be constructed this summer.

Clarion, Ia.—Farmers and business men in general throughout Northwest Iowa are deeply interested in the scheme for an electric railway to the Mississippi River.

Clinton, Ia.—The State Electric Street Railway Company was lately voted a franchise here. The company will spend $150,000 in rebuilding and re-equipping its line.

Decatur, Neb.—The townships of Decatur, Riverside and Silver Creek, will vote on the proposition to issue $20,000 bonds for the construction of an electric railway from Omaha to Sioux City.

Elgin, Ill.—The Elgin-Aurora & Southern Traction Company will build a branch road.

New Castle, Ky.—The Fiscal Court of Henry County and the New Castle council will sell an electric railway franchise on April 26. The applicant is the same company that is now putting in an electric light plant and an ice plant at Eminence. It is proposed to connect the two towns, and probably extend the line to the Kentucky River, possibly to the Ohio at Carrollton.

Niles, Mich.—J. S. McMiceal, of Chicago, has been granted a franchise to build an electric line through the township.

Noblesville, Ind.—The Indiana Union Traction Company will soon begin work on the extension of its line.

Owosso, Mich.—Frank Westcott is interested in a new electric road from Grand Rapids to Ionia.

Patton, Pa.—Promoters of the new trolley line through the north of Cambria County, connecting this place, Hastings, Barnesboro, Spangler and Carrolltown, have given out the information that they have closed a deal which virtually assures the building of the road at an early date.

Pittsburg, Pa.—A large force of men is at work building the new electric road which will connect West View with Bellevue. This line will be finished before summer.

St. Joseph, Mo.—The Maryville & St. Joseph Electric Railway Company has been granted the right of way in this city.

Uniontown, W. Va.—The Elkins Syndicate of West Virginia, which already controls lines in this State, is reported to have decided to build a line from Morgantown to this place.

Wheeling, W. Va.—The Wheeling Traction Company will extend its line from Alexander to Clayville, Pa.

POWER PLANTS.

Elkhart, Ind.—Ex-Congressman C. G. Conn has purchased Gov. Durbin's interest in the Elkhart Power Company, organized by Walter Brown, and which was intended to absorb two local hydraulic companies in which Mr Conn held stock. Mr. Conn is now in control of the entire project, and he proposes to invest $1,000,000 in the electric plant.

Lewiston, Ida.—Francis Jenkins, of Moscow, has just completed a deal with John C. Bender, of this city, for the purchase of Mr. Bender's water right at Elk Creek Falls, about 50 miles from here in the North Fork country. Mr. Jenkins will at once organize a company to develop electric power there to be transmitted through the Patlach and Palouse countries for running the electric railways and light plants.

Virginia City, Nev.—It is reported that O. Bealu will install an electric power plant for the operation of his mill on the Chollar lease croppings.

BIDS WANTED.

Pinckneyville, Ill.—Sealed proposals will be received until May 2 by J. C. Namm, city clerk, Box 106, for the construction of an electric light plant.

Richmond, Ind.—The trustees of Earlham College, of which Joseph J. Mills is president. will receive bids for wiring Lindley Hall, and for a system of wiring for the college grounds.

Traverse City, Mich.—Sealed bids will be received until May 31 for the lighting of the streets and alleys of this city. Address Charles M. Beers, city clerk.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 13⅛@13¼c.; Lake 13¼@13⅜c.; casting, 13@13⅛c.

The Lowell (Mass.) Electric Light Company has declared a dividend of $4 per share, payable May 2.

The Montreal Street Railway Company has signed a contract for new equipment amounting to $300,000.

Redmond, Kerr & Co. of New York will pay the coupons of the St. Joseph Light, Heat & Power Company 5s, due May 1.

The Fox River Light, Heat & Power Company of Elgin, Ill., has purchased the Aurora, Elgin & Chicago Power Company.

President Dolan, of the United Gas Improvement Company, Philadelphia, emphatically denies that his company will absorb the Philadelphia Electric Company.

The directors of the Edison Electric Illuminating Company of Boston have declared a regular quarterly dividend of 2½ per cent. and made the same payable May 2.

According to an officer of the Chicago Union Traction Company earnings for the first half of April were fully 15 per cent. in excess of the same period last year.

The directors of the American Telephone Company unanimously confirmed the action of the finance committee in the recent sale of $20,000,000 three-year 5 per cent. notes.

It is understood that the directors of the Chicago Edison Company have declared the regular quarterly dividend, payable May 1. Books close a week preceding the payment.

Lancaster (Pa.) dispatches state that the Philadelphia, Coatesville and Lancaster Railway has bought the Brandywine Electric Street Railway, and will issue $600,000 bonds to pay for the purchase.

At the meeting of the Marconi Telegram Company in Jersey City on Monday, James W. Pyke, J. P. Cotton, H. H. McClure and G. Marconi were elected directors to serve for the ensuing year.

An order was entered at the Appellate Division of the Supreme Court, New York, fixing the compensation for each member of the Board of Rapid Transit Commissioners at $5,000 for the year 1903.

The Havana (Cuba) Electric Railway Company reports for the calendar year gross earnings $1,061,709, and surplus, after charges, of $30,235, against gross of $864,865 and a deficit, after charges of $21,861, in 1902.

The Appellate Division of the Supreme Court, New York, handed down a decision granting the motion for the appointment of commissioners to investigate and report whether or not the Westchester Rapid Transit system should be constructed and operated.

It was stated positively in Wall street Saturday that the directors of the Allis-Chalmers Company have suspended dividends on the preferred stock, but on Monday E. D. Adams, who owns a controlling interest in the concern, stated that no action had as yet been taken by the directors in regard to the dividend.

A statement has been given to the press that the General Electric Company is in a strong financial position and never again expects to have to wrestle with debts, whatever may be the size of any industrial depression. That is why, it claims, it will sell stock even to take care of such a small matter as the $3,000,000 of debt inherited from the Stanley Electric Company.

2-3 Actual Size.

ELECTRICAL ENGINEER'S POCKET BOOK,

Sent Prepaid on receipt of $5.00

A Compendium of Useful Information treating of the latest and best practice in Electrical Engineering.

By HORATIO A. FOSTER

Member Amer. Inst. E. E. Member Am. Soc. M. E.

(*WITH THE COLLABORATION OF EMINENT SPECIALISTS.*

Made especially for those whose living comes from practical daily work; for those who design, construct, and install electrical apparatus. It bears the same relation to Electrical matters, as Kent's and Haswell's Hand Books do to Engineering. While it is not intended as a text book, it serves many text book ends. It not only contains all that all of the text books contain, but goes on from where they leave off, and from first to last, is carried along intensely practical lines. It contains nearly 1000 pages of matter; all meat, no padding, nothing superfluous; there is nothing in it that should be left out and nothing left out that should be in. It is really a condensed set of 29 volumes on electricity, and its uses and any one of the 29 sections making up the whole, would make a very respectable two dollar book. The author has had the cooperation of the best authorities, each in his chosen field, to the end that the information given, be just exactly right. To further this information and to more carefully explain the text, nearly 800 illustrations are used, all of which, with perhaps a very few exceptions, have been especially made for this book alone. There are 486 tables covering all sorts of electrical matters, so that immediate reference can be made without resort to figuring.

Anyone making a pretense to Electrical Engineering, needs this book, 'tisn't a matter of "how much" or "how little," the cost may be, it's a matter of how quick they can get a copy in their possession, it is a real necessity and for their own daily good.

The cost—a five dollar bill—isn't worth considering for a minute, the cost will come back in information manyfold.

An index to the contents means too much space here. An index will be sent on request.

$5.00 gets a copy sent prepaid.

D. VAN NOSTRAND COMPANY,

23 Murray Street and 27 Warren Sts., New York.

Publishers and Booksellers.

ELECTRICITY.

VOL. XXVI. NEW YORK, APRIL 27, 1904. NO. 17.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

The Louisiana Purchase Exposition.

Before we go to press again the Louisiana Purchase Exposition in St. Louis will be formally opened by the pressing of an electrical button in Washington by President Roosevelt. The closing of the electric circuit by means of this button at noon on April 30 will set in operation various departments of the exhibition, which commemorates the purchase of Louisiana by the United States from the French in 1803.

As usually happens with most world fairs of this magnitude the date of opening had to be postponed from 1903 to 1904, but if anything the exhibition as a whole will have gained by the enforced delay.

The fair grounds are situated just west of the city and comprise 1,240 acres, of which one-fifth is under cover.

The buildings are multitudinous and of beautiful and original design.

The Palace of Electricity covers an area of about 350,000 square feet and cost approximately $400,000. Here will be located a majority of the electrical attractions, which may be classified into three main groups—electrical exhibits, the generation and transmission of electrical power, and spectacular lighting features.

Exhibits of electrical machinery or apparatus will be in evidence from every prominent nation in the world with one or two exceptions. France, Germany and Great Britain have a very large amount of floor space, but even such countries as Brazil and Mexico will be represented.

There will be a practical demonstration of wireless telegraphy and arrangements will be made for sending messages to various cities.

The illuminating features will surpass anything heretofore attempted and the largest searchlight in the world, rated at 6,000,000 candle-power, will flash from the top of a building near the grounds.

Arrangements have wisely been made for holding a number of congresses at St. Louis during the Exposition. The most important to the electrical fraternity will be the meeting of the International Electrical Congress, which will be held between September 12 and 17. At this gathering there will be present prominent scientists and electrical engineers from almost every civilized country of the globe, who will be prepared to discuss subjects of vital importance to the welfare of the world in general and to the electrical industry in particular

Space will not permit of enumerating all of the electrical features of the Exposition, and as in the case of world's fairs in the past it will be necessary to go there to appreciate them.

* * *

A Protest Against Wireless Telegraphy.

The stand taken by Russia with regard to the use of wireless telegraphy within what may be termed the war zone in the far East opens up a question which will in all probability ultimately lead to an international conference. The text of the communication from the Russian Government to the State Department and which was sent to all foreign offices is as follows:

"In a case in which neutral steamers having on board correspondents who might communicate war news to the enemy by means of perfected apparatus not being yet foreseen by existing conventions would be arrested near the coast of Kuantong or in the zone of operations of the Russian fleet, the correspondents will be looked upon as spies and the steamers

furnished with wireless telegraphy seized as prizes of war."

This order, it is alleged, is aimed at a newspaper dispatch boat equipped with wireless apparatus and with American operators aboard.

The right of the Russian authorities to prevent the sending of wireless news which might be caught by Japanese ships is not questioned, but the declaration that newspaper correspondents will be regarded as spies is to say the least drastic.

At a recent meeting of the Cabinet in Washington the opinion was expressed that it would be desirable, if not indeed absolutely necessary, for this Government to control, at least in a supervisory way, the operation of wireless telegraphy, particularly along the coast. Stations for the receipt of wireless messages are springing up at various places along both the Atlantic and Pacific coasts. It was pointed out that in the event of war with a foreign nation it might be necessary in defense of the nation for officers of the United States to have charge of these stations as a means of assurance to the government that no communication was established with vessels of the enemy's fleet and that the system was not employed to the detriment of the interests of the United States.

Thus far wireless telegraphy has not figured in international affairs, and no conventions covering its use have been considered. It is believed that sooner or later the subject will be taken up by diplomats with a view of reaching an international agreement. What that agreement will be cannot be foretold, of course; but in the meantime it is the opinion of officials of this Government that measures should be adopted to protect the Government against such employment of the wireless system as might be injurious to the nation.

It is stated on good authority that so far as Russia's protest goes no action will be taken by the State Department, unless some specific case involving an American citizen occurs.

* * *

Electric Trains Stop Running. The Liverpool & Southport Electric Railway in England, which was described and illustrated recently in ELECTRICITY, commenced running its trains for the public, according to our London correspondent, on April 5. On April 11, however, operations were obliged to be suspended because a serious subsidence of the generating station had occurred. The electric trains are now idle, and steam trains have had to be reintroduced. The sandy nature of the subsoil is responsible for the subsidence, and it is evident that adequate provision had not been made against such a disaster. It is quite uncertain when the electric trains will again be run.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Richard H. Pierce, of Boston, has been appointed chief engineer for the power plant at the World's Fair. He was consulting engineer at the Columbian Exposition.

Electric automobiles, a special cable dispatch from Paris states, are running petroleum driven vehicles hard.

Governor Odell will give a hearing at the Executive Mansion in Albany at 10 A.M. to-morrow (Thursday) on the Niagara, Lockport and Ontario Power Company bill.

The Buenos Ayres Grand National Tramways Company, Ltd., is to convert its horse car system to electric traction at an estimated cost of $4,000,000. A large portion of the equipment will be bought in the United States.

It is understood that the annual report of the General Electric Company, covering the year ended January 31, is in the hands of the printers. It is stated that the earnings for the year, after the usual drastic writing off of plant and machinery, will be equal to 25 per cent. on the capital stock.

Messrs. Siemens & Halske, of Berlin, according to the London *Electrical Engineer*, have recently patented a telephone which is intended for use exclusively in situations where cross-connections may occur between the telephone conductors and high-tension circuits. The feature of the instrument is that there are no metal parts outside the case which can be touched.

A German technical paper, discoursing on the turbine, of which we hear and expect so much in these days, reminds its readers that it is by no means an idea new in mechanics. Twenty-seven hundred years ago, in the little nation of the Chaldees, adjoining Armenia, the water turbine was known, and built, and used in milling. It was then called the "shell wheel." The wheel was used in a horizontal position, no effort being made to secure the greater value of the water pressure. The wheel was connected to a vertical shaft which turned the stone and ground the grain into a coarse flour. Near the city of Van, believed to have been built 2,000 years B.C., there still remains canals in a good state of preservation. One of them, 60 miles long, is now used for irrigation and power. At one time, centuries ago, there were 40 mills on this canal, and to-day the remains of these ancient institutions may be seen. Flour mills, driven by these simple turbines, of the same type as was used there 2,700 years ago, are still in operation.

Prof. C. F. Burgess and Carl Hambouchin, of the College of Engineering of the University of Wisconsin, it is claimed, have discovered a method of making pure iron at a small cost. By the new discovery, which is the result of three years of research, the product can be made for one cent a pound. The process is similar to that used in refining copper, an electric current taking the impure iron from the plate and depositing it in a pure state on another plate. The pure iron has properties not possessed by ordinary iron or steel. On account of its electrical properties it is a valuable material for the construction of electrical apparatus, and it furnishes the means for making special steel alloys of great strength and hardness.

The question of working the various Alpine tunnels by electricity is being seriously discussed in Switzerland. The Erstfeld-Bellinzona section has been used as an experiment, and the results obtained promise so great an economy in the working of the whole of the St. Gothard line that the adoption of electric traction may be expected at no distant date. The question of electric traction for the Simplon Tunnel is also being raised.

The U. S. Government will exhibit at the St. Louis Exposition specimens of every known radio-active substance, radium compounds, and much other material on the subject.

Three hundred and twenty acres of land near Baker City, Oregon, are soon to be irrigated by means of electricity. The land is too high up on the bench to divert water from the river. There is an abundance of water flowing underneath this land at a depth of about 20 feet. Experiments made last season demonstrated that this source of supply was constant and abundant. There is an electric transmission line which conveys electric power to one of the mines which passes over this land. Arrangements have been made to put in electric pumps to pump water from large wells. A 5 hp. motor will drive a pump that will raise 320 gallons of water per minute, which is sufficient for 80 acres of land.

SINGLE-PHASE ALTERNATING CURRENT RAILWAYS.

BY FRANK C. PERKINS.

The advantages to be gained by the use of a single-phase electric railway system, with a successful motor of this type, are many, and quite a number of prominent engineers have been solving this problem and are working on this line both in this country and abroad. By this railway system the sub-station with its rotary converters is eliminated and the transformers are only of the stationary type, if used at all, as the high tension transmission voltage may be used directly on the trolley line, which consists of a single working conductor. In case extremely high voltages are employed for transmission of power great distances, at from 30,000 to 60,000 volts, the static step-down transformers are simple and do not involve rotary machines at the sub-stations.

With the single-phase high tension railway system it is possible to work on long trunk line railways, current being supplied from hydro-electric plants and steam plants located favorably at coal mines or near a supply of natural gas even at considerable distances from the railways. The advantage of the single-phase system over the polyphase system, should a highly efficient and satisfactory motor of the former type be developed for traction work, would be that a single conductor only would be required as in the direct current system, while the polyphase railway requires at least two above the track with the rails as a third conductor, or, as on the Berlin-Zossen road, three overhead conductors at the side of the track.

A patent was granted to Charles Zipernowsky of Buda-Pest, Austria-Hungary, by the United States in 1893 for a system of supplying current to railways, the intention being to supply an extended area with suitable current in an economical manner. According to these designs a single-phase current is employed for the transmission of the power at high tension and alternating current motors, and direct current generators are employed similar to the polyphase direct current railway systems now so largely employed in this country and abroad. The direct current machines supply a continuous current to the working railway conductors. As direct current motors are employed on the electric locomotive or motor car this can hardly be called a single-phase railway system although alternating currents of this character are evidently used for transmitting the power from the central station as only two conductors are indicated. In reference to this system Mr. Zipernowsky says: "To advantageously conduct electrical energy to great distances it is necessary, as is well known, to use high tensions, and this requirement is for practical reasons only to be met by the use of the alternating current. In the production of continuous currents it is difficult or even impossible to produce such high tensions as, for instance, 10,000 volts or over, while on the other hand such tensions, as is well known, are practically applicable with alternating currents. Alternating currents of high tension and conducted to great distances are conveniently transformed afterward at the places of consumption into currents of any desired tension."

Mr. C. J. Vandepoele was granted a patent in 1890 for an alternating current railways system using static transformers upon the locomotive or train. These transformers were intended to be used for reducing the potential of the current which is collected from the working conductors at high pressure, the current of low tension from the transformers being conducted to the alternating current motors on the car.

Alternating current systems have also been patented by George Westinghouse and C. F. Scott, reducing the leakage under normal circumstances, with automatic devices for supplying full current to the working conductors when the train is passing along a given section of the line. The patent drawings show an automatic alternating current railway system providing means for closing the primary circuits of the transformers as the trains pass. S. Z. De Ferranti and Carl Coerper have patents for obviating the loss due to the primary circuits of the transformers being normally closed along the entire length of the railway line.

A single-phase alternating current system has been proposed by Mordey and Jenkin in England, using the Ward-Leonard method of speed regulation. They propose employing an induction motor driving a direct current dynamo, whose voltage may be varied as desired by the field rheostat while operating at constant speed, and supplying the direct current to the railway motors at low voltage, giving a very heavy starting torque with the use of very little power. This scheme involves the use of a motor-generator set on the train operated at constant speed from the single-phase high tension line, which is connected directly to the motor terminals. By this means all starting resistances are avoided and the speed of the motors may be regulated entirely by means of the field rheostat of the generator of the motor-generator set.

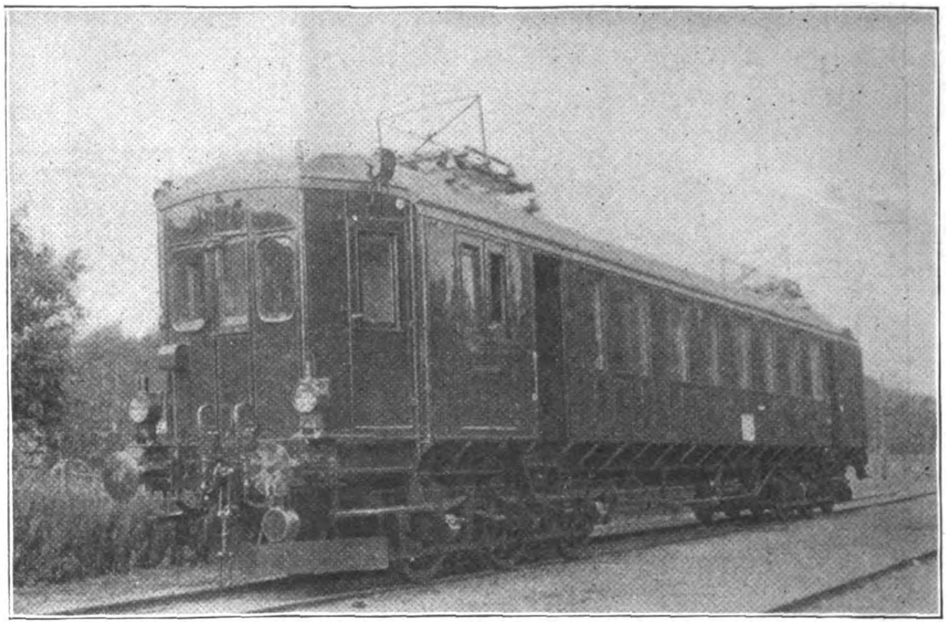

Fig. 1.—Electric Car on Single-Phase Line.

A new German single-phase high tension railway system is being tried on the branch of the German State Railways between Johannisthal, Spindlersfeld and Niederschoneweide, located not far from Berlin. The accompanying illustrations, Figs. 1 and 2, show the track construction as well as the overhead construction, a single trolley wire only being necessary from which to collect the required power. The single-phase alternating current employed has a frequency of 25 cycles per second and is conducted to the car motors at 6,000 volts directly from the overhead trolley wire. This wire is suspended in places by two parallel steel wires and connected by cross wires at short intervals, and in other places by a single steel wire

above the working conductor, the former acting as feeders to a certain extent, as they are not insulated from the trolley wire but are all carefully insulated from the ground.

The current is conducted to the motors on the cars by a couple of sliding bows, one at each end of the locomotive or motor car, and the doors leading to the high tension apparatus are so arranged that they cannot be opened as long as the collecting bows are in contact with the high tension trolley wire. This precludes any possibility of an accident by carelessness on the part of the attendant, as the door can only be opened after taking off the collectors, the latter remaining off until the door is again closed.

The single-phase electric motor which makes this high tension railway possible between Spindlersfeld and Niederschoneweide, was designed by Winter and Eichberg and was constructed by the Union Elektricitats Gesellschaft of Berlin, Germany. It is claimed that no energy is wasted by external resistances in the regulation of speed of this motor and it is possible to wind the motor for very high voltages directly applied. The gear ratio used is 1 : 4.26 and the wheel diameter is one meter, while each of the two motors which are of the four-pole type has a capacity of 125 hp. The electrical equipment weighs somewhat over six tons while the total weight of the locomotive or motor car is about 60 tons, the latter carrying about 50 passengers of first and second class. The trains will include two locomotive cars, one in front and one in the rear, and several ordinary cars between, with multiple unit control, the speeds not being particularly high, varying above and below 40 km. per hour.

A new single-phase railway motor employed on the Spindlersfeld road and constructed by the Union Electricitats Actien Gesellschaft of Berlin is said to have a comparatively large air gap and yet to have all of the advantageous qualities of the series railway direct current motor, rapidly increasing in speed at small loads and also giving a very satisfactory starting torque. If these claims are found to be justified there is no question but that the single-phase railway will soon be extensively installed not only in Europe but throughout America as well. A number of prominent American railway engineers have been working on the single-phase railway problem and it is stated have been very successful in their efforts. A number of single-phase railways of considerable length can be expected in this country at no distant date if the success reported for this alternating current system is assured.

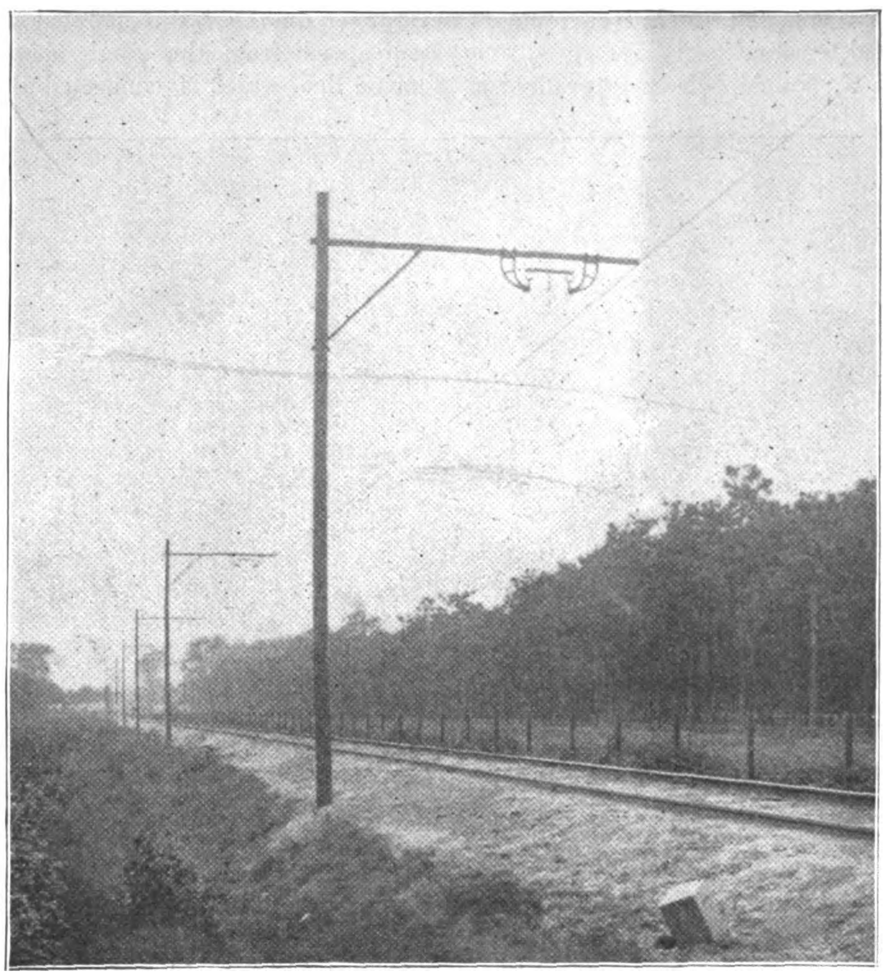

Fig 2.—View of Line, Single Phase Railway.

ELECTRICAL STATION PRACTICE.

ARTICLE XXXIV.

BY W. H. RADCLIFFE.

The plan of organization in an electrical station of medium size is generally as follows: At the head of the list are the stockholders whose opinions are voiced by the directors, and from the directors are chosen the executive committee which in turn selects the president. Under the president are the counsel, and the secretary and treasurer who keeps the funds and records. In addition to these the general manager, the general superintendent, the superintendent of construction, and the station engineer are under the president's supervision. Next to be mentioned are the steam engineer and fireman, the dynamo tender and cleaner, the lineman, lamp trimmers and night inspector; also the cashier, book-keeper, collector, and the storeroom keeper. This staff is conveniently divided into two sections, that of the office or financial department, and that of the station or operating department. In this series the management of the station or operating department is of primary importance and will be considered in the present article.

The most important factor in the successful operation of a given electrical station is the class of attendants employed. They should be chosen primarily for the knowledge and skill they possess in the performance of their duties, but hardly less in importance are the qualifications of sobriety and honesty. To secure and hold such men it is necessary to pay good wages, but money thus invested will bring good returns. One cheap man through carelessness will often damage and waste far more than the difference between the salary of a good man and that of his, can replace. It is true the pay roll forms the largest item in the operating expenses of an electrical station and should therefore be carefully watched, but to be consistent the cost of maintenance and depreciation must likewise be considered and compared with the salary account, as should also the number of accidents requiring a shut down of the plant. The last mentioned feature may not appeal so forcibly to one dealing only with dollars and cents, but frequent occurrences of this nature are apt to shake the confidence of the public and sooner or later assert itself in the patronage received.

The keynote of success in the manage-

ment of station employes is *system.* Without a system in which each person has certain duties assigned to him, it is almost impossible when an accident or blunder occurs to accurately fix the blame where it belongs. Not so, however, when the work to be done is properly divided and each task formally assigned to some one person who will thereafter be held accountable for the proper performance of the same.

Turning our attention now to the means that should be provided within an electrical station to facilitate the work of the employes, we will commence at the office for the officials. A desk, provided with pen, ink, pencil, erasers and scratch paper, should be installed therein for use in writing out daily reports, which as will presently be shown, are absolutely necessary in the systematic operation of the station. In order to keep a check on what is being done in a station, accurate reports should be required of the foreman in each department if the station be a large one; in a small or medium sized station, however, one report blank may be found to answer the purpose of all departments.

The report blank for an electric lighting station of moderate size should be ruled and printed in a similar form to that shown in Fig. 35. It is assumed, here, there are in commission four generators, numbered 1, 2, 3 and 4; two engines numbered 1 and 2, and two boilers also numbered 1 and 2. At the top of the blank appears the name of the electric lighting company, the name of the report and the date. At the extreme left is provided a column for recording the exact time at which observations are taken; this column, therefore, shows the exact time over which the report extends, and is generally one day, from midnight to midnight, during which half-hour readings of the volts and amperes supplied by each of the four generators should be

REMARKS.

Signed .... Chief Engineer.

FIG. 35.

taken and recorded in the proper columns under the respective letters V and A. In the first three columns at the upper right-hand portion of the report are recorded the times of starting and stopping, together with the number of hours' run made by the four generators, the two engines, and the two boilers. In the last three columns of this portion of the report are entered the average volts, the average amperes, and the number of kilowatt-hours supplied by the four generators during the 24 hours. These values are calculated from the half-hour readings recorded in the columns 1, 2, 3 and 4.

The determination of the average number of arc and incandescent lamps lighted during the 24 hours is important in that the receipts of an electric lighting company is generally estimated upon this average number of lamps as a basis. It may be well, therefore, to give the method of procedure in obtaining these figures. The average number of arc lamps lighted may be calculated directly from the average pressure of the arc light generator by dividing this number of volts by 50, the voltage of each lamp. The average number of incandescent lamps lighted is calculated from the average current of the alternator supplying the circuit. The standard for comparison is the 50 watt, 16 candle power, incandescent lamp which at 100 volts requires one-half ampere. From the ratio of the transformer employed, is determined the number of amperes in the secondary or lamp circuit for each ampere in the primary or alternator circuit; this of course will be inversely proportional to the ratio between the secondary and primary voltages. Since each lamp requires one-half ampere, the number of lamps supplied per ampere of primary current will be twice the corresponding number of amperes in the secondary circuit. Having now the number of lamps lighted for each ampere of primary current, this number multiplied by the average value of the primary current will give the average number of incandescent lamps lighted. From this figure the number of lamp hours may be determined if it be multiplied by the time in hours during which the alternator is supplying current to the lamps. Expressed in this manner the output is in a convenient form for comparison, or it may be that the total number of kilowatt-hours of output is preferable. In either case the information on this subject should be entered on the report as shown in Fig. 35.

Under the heading of Supplies Received should be entered every article of merchandise purchased during the 24 hours for the operation of the plant, and under Supplies Used must be recorded the amounts of the various supplies on hand that are used during this time. Under the heading of Remarks everything of particular importance in the operation of the boilers, engines, generators, or circuits should be noted; this comprises, of course, whatever accidents occur, their causes and results, the cleaning of boilers, and other affairs of similar nature that are necessary to make the report both complete and intelligible. If at any time the space provided on the report blank for Remarks is not sufficiently large, a separate sheet should be attached to the report blank and the remarks recorded thereon. At the lower right-hand corner of the blank a space is left, as shown, for the signature of the chief engineer.

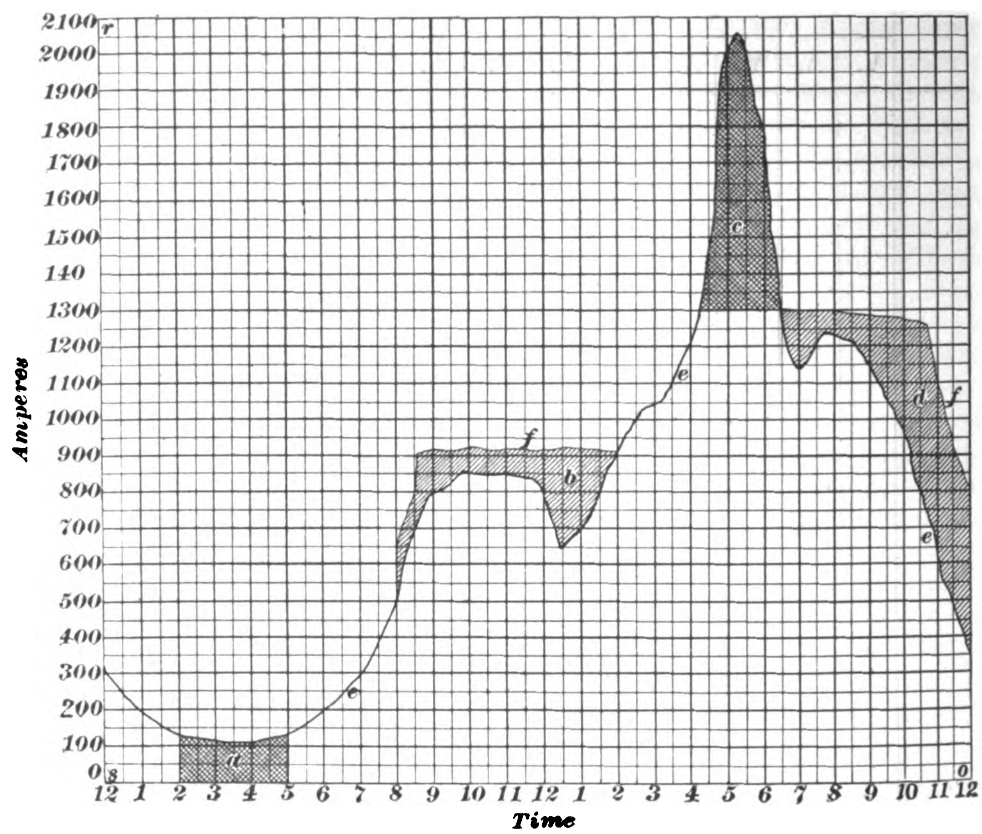

FIG. 36.

The readings recorded in the columns of a report may be rendered much more significant if they be plotted upon co-ordinate paper and a curve drawn. Station load curves thus obtained are particularly desirable for office use, and as an example the load curve for an electric lighting station equipped with a 110 volt, constant-potential generator and a storage battery, is presented in Fig. 36. Upon the horizontal line *s o* the time is laid off in hours, and upon the vertical line *s r* the current is laid off in amperes. The load curve is shown at *e e e*, and the shaded areas *a* and *c* represent the number of ampere-hours supplied by the battery to the line wires. Between the lines *f* and *f* and the curve *e e e*, the shaded portions represent the number of ampere-hours supplied by the generator in charging the battery. Following the plot from left to right it is seen that at 12 A.M. the generator was supplying the line with 300 amperes of current; that the current required diminished gradually during the next two hours, and at the end of that time the generator was replaced by the storage battery which latter supplied the current until 5 A.M. At this time the generator was again called into service to meet the increase of current required. At 8 A.M. a portion of the current from the generator was passed through the storage battery for the purpose of charging it, and the charging process was continued until 2 P.M. when the battery was found to be fully charged and was therefore disconnected. From 12:30 P.M. until about 5:15 P.M. the load increased rapidly reaching a maximum of 2,050 amperes at the latter time. Inasmuch as the maximum capacity of the generator was but 1,300 amperes, the storage battery was switched in multiple with the generator when the load reached this amount and supplied all the current required in addition to the 1,300 amperes. At 6:30 P.M. the load became sufficiently low to permit of a portion of the generator current being again used to charge the battery, and the plot shows that the charging process was continued throughout the remainder of the 24 hours.

An examination of the load curve in

Fig. 36 will suggest that between 2 A.M. and 5 A.M. while the generator, engine, etc., were not running, an excellent opportunity was afforded for cleaning or for repairing the machinery. The shaded portion *c* representing the amount of current supplied by the battery in excess of the maximum capacity of the generator is called the peak of the load, and it is in providing for this peak that a storage battery is of particular value for otherwise larger generators or a greater number of them would be necessary. This addition would not only increase the cost of the plant, but it would decrease its efficiency as a whole on account of the necessity of operating the generators and their respective engines during the greater portion of the time below their normal capacities and therefore at decreased efficiencies.

In issuing orders from the office, free use should be made of a bulletin board. Hereon should be posted by means of thumb-tacks any notices affecting the operation of the station, orders for revisions or corrections of preceding notices, and warnings regarding the use of high pressure circuits, etc. The bulletin board should be mounted within the station near the office, and in as conspicuous a position as possible; it should, however, be placed so as to be conveniently reached and read by all of the employes.

In keeping the time of employes a system of brass checks has been found to give good results. Each check has a number stamped upon it, and the employes are each given a number corresponding to that on one of the checks. The checks are hung on pegs mounted upon a board, the pegs being also numbered to correspond to the checks. This board containing the brass checks is hung outside the office about ten minutes before the time to commence work, and beside it is placed a box into which the employes are requested to drop their respective checks. It is advisable to place some one in charge of the board while it is being used to see that no employe removes any but his own check. As the whistle blows for commencing work, the box containing the checks of those on time is removed and replaced by an empty box which is left out for half an hour. An examination of the board and the contents of the second box will reveal at once those whose salary must be docked. The same procedure should be repeated at noon time, and an accurate account kept of the delinquent ones.

Next in importance to a well equipped office in the systematic management of an electrical station, is a well designed and properly equipped storeroom. This room should contain everything of a portable nature used in the operation of the station. Such articles should be kept under lock and key, and given out only as specified in orders written by the foreman. Printed order blanks should be used for the purpose and these when filled out and submitted should be placed on file and referred to in keeping the stock books and accounts. In a large station, the supplies should be in charge of one man whose duty it should be to keep account of all articles received and given out. In a small or medium sized station, the storeroom keeper may be assigned to other duties in connection to those just mentioned, but they should be such as not to necessitate his absence from the storeroom for an appreciable length of time. He may, for example, balance up the books, make out the daily reports, keep the time records of the employes, plot load curves, and do other work of a similar nature. It will be found in many stations that a storeroom conducted in this manner would more than pay for itself and keeper if consideration be taken of the daily loss and waste of supplies resulting from carelessness on the part of employes when no such system is in use.

In the management of a station every effort should be exerted to afford it the greatest protection in case of fire. Pump, pipes, hose, and fire-buckets should be installed in the station as already explained, and experience has shown that a well-organized fire company among the employes is of great value. In the latter case, each man should be assigned to a certain task in order that all of the station attendants may be employed to the greatest advantage.

OIL SWITCHES FOR HIGH TENSIONS.

The *Elektrotechnische Zeitschrift* publishes a belated report of an interesting paper read by Herr Vogelsang before the Electrotechnische Gesellschaft zu Koln, in which the author deals with oil switches for high tensions. After reviewing the changes which have been rung in the designs for high-tension generating plants since the first transmission scheme was carried out, the author goes on to say that modern practice has discovered two ways of constructing high-tension switches which can be relied upon to satisfy the more exacting requirements of to-day. One of these methods consists in the employment of the horn-break type of switch, while the other embodies the principle of interrupting the circuit under oil. Each has its advantages and disadvantages; the horn-break is only effective with heavy currents—the greater the current the more reliable is its action —a peculiarity which renders it especially adapted for use with fuses. On the other hand, the space which is required for its proper function is considerable. The author goes on to discuss the oil switch—incidentally describing a type constructed by Voigt and Haeffner, Frankfort-on-Main, which is exceedingly simple. A three-pole switch is provided with six contact jaws, to engage with which there are three blades, so that each pole is interrupted at two points simultaneously. The oil is contained in a removable vessel of tin. To those who have had to do with high-tension switches of other kinds, the quiet action of the above type is somewhat surprising, the interruption of the circuit being unaccompanied by noise. Experiments have shown that the formation of an arc under oil, just as in air, depends very largely upon the speed of the break. The author is of the opinion that the advantage of providing a large number of break points, especially in oil switches designed for very high tensions, will be more appreciated in the future, and thinks this principle better than that adopted by American engineers of employing extra long breaks under oil. He also points out that oil fuses are much less satisfactory in action than oil switches because in their case one point of interruption only per pole can be provided. Moreover, at the moment of interruption the particles of melted metal along the path of the fuse assist the formation of an arc. For this reason oil fuses are used only for moderately high pressures, that is up to 3,000 volts, and for relatively small currents. Within this limit oil fuses have proved thoroughly reliable. On the other hand, combination oil switches, in which the ordinary switch blades are replaced by fuses, have met with considerable success, especially in mines. But the practice of employing automatic cut-outs, instead of fuses, in conjunction with oil switches is quickly gaining favor, and it would almost seem that the use of oil switches with automatic releases in place of ordinary switches and special fuses has solved the difficulty hitherto connected with the breaking of high-tension circuits. The advantages of such an arrangement are obvious, especially in that the danger of fire which, in unfavorable circumstances, attends the blowing of high-tension fuses is avoided. In regard to oil switches with maximum current releases, the action is always indirect, being effected either by continuous current through the

medium of a relay or by alternating current through a rectifier. The latest phase in the development of this class of apparatus is the construction of automatic oil switches and cut-outs which can be operated from a distance. It is probable that this type of switch will find extensive employment for central-station work. Some interesting details of the several designs mentioned are included.—*Electrical Engineer, London.*

THE LATEST PROGRESS IN WIRELESS TELEGRAPHY.

BY EMILE GUARINI.

Translated for "Electricity" by Jean A. Wetmore, M. S., E. E.

(*Continued from page 215.*)

It will be interesting to observe the effects of the wind and the atmosphere upon the capacity of the antenna and consequently upon the length of the waves, during a relatively long period of time; for it is a fact that the wind varies the position of the wires in the antenna in respect to the earth and in regard to each other. Atmospheric variations, furthermore, cause a variation in the nature of the dielectric of the condenser, which is connected to both the antenna and earth.

As these variations are not the same at the two stations at the same moment, we can see that bad syntonization results from this fact.

As to devices for eliminating the effects of atmospheric disturbances, M. Ferrie has cited those of Messrs. Voirsenet-Tissot, Magne, Jehenne & Martin, Monnier, etc., but, as he has stated, none of them completely fulfills the requirements, which results in part from the fact that these phenomena are of an exceedingly variable and of little known character and that all of them cannot be prevented at the same time. The only means of suppressing the effect of the greater number is by considerably increasing the energy of the transmission and by using receivers of very low sensitivity, and it must be understood, a much greater energy in the transmitter. We have held to this opinion for a long time, and, furthermore, it is the simplest and surely the shortest means.

M. Ferrie then remarked further in regard to transmission troubles, that the theory recently proposed by Mr. Nordmann regarding the aurora borealis and of the presence of Hertzian waves in the atmosphere, seemed capable of explaining certain classes of these troubles, especially since the same transmission troubles were encountered by all the various users of new instruments.

We are given to understand that Mr. Marconi has installed two "Hertzian mills"—this expression of M. Ferrie is only too exact—at Poldhu and at Cape Cod, of 100 hp. each, for the purpose of communicating between England and America and without interfering with the ordinary stations in the near vicinity. For the purpose of utilizing the energy at his disposal, Mr. Marconi has recourse to commercial transformers, with a factor of 10, operated by a 2,000 volt alternating current. The device used for transforming this energy into Hertzian waves is shown in Fig. 9. A condenser, K, is ployed two self-inductors, F, F[1], one of them, F[1], is adjustible, and the other, F, has an impedance of such a character, that being in circuit, it prevents a flaming of the arc at C. The Morse signals are produced by a key, M, placed in shunt from the coil F.

Although no one has had any definite information respecting the length of the wave or of the antenna at Poldhu or Cape Cod, it is quite certain that this length is very great, taking into consideration the immense size of the antenna. This is the explanation why signals from Poldhu have never seriously inconvenienced the neighboring stations, particularly the one at Brest, 250 km. away.

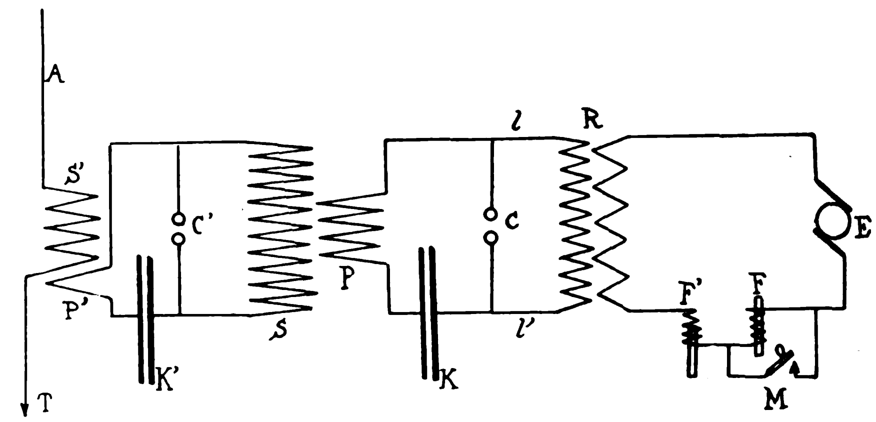

FIG. 9.

placed in derivation (shunt) to the terminals of the secondary of an industrial transformer, R, which is so chosen as to have such a capacity as to place it in resonance with the secondary. This condenser is discharged through an oscillator C, across the primary, P, of a Tesla transformer, which sets up oscillations having a very great wave length. These latter oscillations induce others, having a similar frequency, in the secondary, S, of a Tesla transformer and these last oscillations are used to charge a second condenser, K[1], to a very high tension, and this condenser in its turn is discharged through an oscillator, C[1], which is placed across the primary, P[1], of a second Tesla transformer, whose secondary, S[1], is connected to the antenna and also to earth. The capacity of K[1] is so determined that the oscillations due to its discharge may be in harmony with the period of the antenna itself. The various adjustments of the condensers and of the Tesla transformers are determined by experimenting. For the purpose of preventing the formation of an arc at the oscillator, C, it becomes necessary some times to blow it out by using a compressed air tube.

The alternating current is regulated in the ordinary manner by the insertion of self-induction governors in the transformer primary. There are usually em-

(Mr. Tissot has, however, written us that he has received dispatches emanating from Cape Lizard.) These stations are provided with antennæ whose wave length is only 200 meters at the greatest, and the multiple resonance produces effects which are much less appreciable than are the period differences themselves.

We will add that first, this proves that stations of different distance capacity cannot be interfered with by another, if widely differing wave lengths are employed; second, that extra powerful stations will remain immune from outside interference on account of the great difficulty in obtaining very great wave lengths. The difficulty from interference will become greater as these stations increase in number. However, here is an argument to support what we have just stated: When M. Ferrie quite recently set up communication between Paris and Belfort, by using antennæ supported by captive balloons, he received both at Paris and Belfort an interminable series of the letter S; the wave length of the antenna was about 2,000 meters; this proves not only that the wave from Poldhu may be received by a receiver not in unison, but also, M. Ferrie remarks, that communication between England and America is not yet an assured fact, as they are all the while at work with the letter S. This

conclusion may be objected to by saying that Mr. Marconi uses the letter S all the while in his experiments with new devices, because it appears to be capable of the greatest distance transmission and because it requires a smaller consumption of energy.

The Military Telegraph Service has, in its course of experiments which were undertaken with the valuable co-operation of the Central Light House Service, tried to secure a comparison of the losses suffered by using a continuous current and induction coils, with those by which the object could be obtained by employing alternating currents. The energy used in all these instances was less than 1 kw.

Directly excited devices, and those of Braun-Marconi, have been used with induction coils, and experiments not only

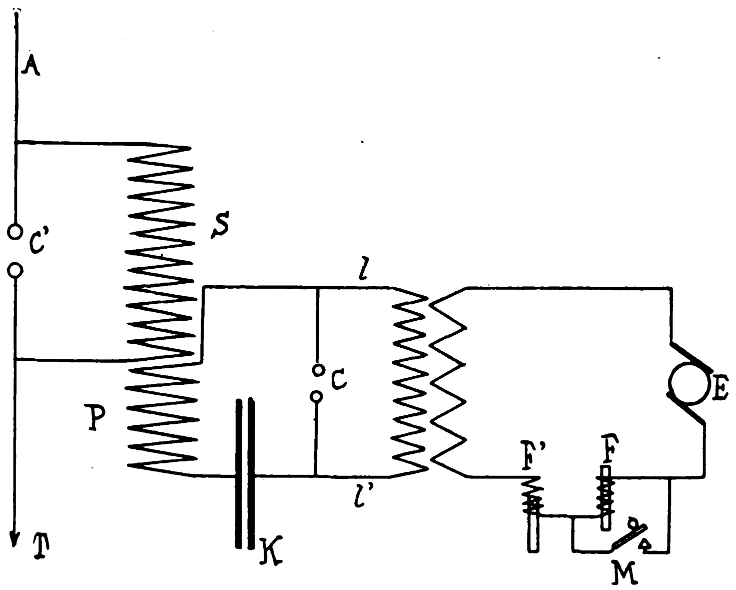

Fig. 10.

with the Marconi devices, but still other arrangements, some of which have been experimented with by M. Blondel in 1900, have been used in conjunction with industrial transformers and alternating currents.

In particular, instead of employing, as Mr. Marconi has done, oscillations of very long wave lengths and of high tension, supplied from the first Tesla transformer (Fig. 9) for the purpose of charging a second condenser, it may be used to charge the antenna, which is discharged through a second oscillator, C^1 (Fig. 10). A better output is thus obtained. This arrangement is analogous to the direct spark device having induction coils. A better output is obtained, in our opinion, first, because there is one less transformer and conseqently there is a smaller loss; second, because here the same thing happens as with a simple directly operated outfit, i.e., that the larger part of the energy becomes dissipated during the first oscillation, whilst in the Marconi device (Fig. 9) the energy is subdivided into a large number of obviously equal oscillations.

For the purpose of still further increasing the output, one can also, as M. Ferrie remarked, use several Tesla transformers in parallel, operated by distinct oscillating circuits, but mounted on the same industrial transformer.

An analogous arrangement has been described, discussed and illustrated by us in the *Scientific American Supplement* of May 9, 1903.

The results, secured by the above-named investigations have been the following: The receiving taking place at the coherer, the advantages secured have been decidedly in favor of induction coils and directly excited apparatus, by which results have been secured at a distance of about 400 km. with a 15 meters height of antenna, although all the other direct excited devices (continuous and alternating currents) have not been able to carry further than 300 km., but it is really necessary to remark that it has not been possible to utilize a much greater energy by using the induction coils, that is to say, to notably increase the carrying distance, whilst by using alternating currents, they were able to utilize a very much greater energy and consequently were able to considerably increase the distance communicated over. But is that truly necessary to successfully telegraph without wires over a long distance? Is there not also an intermediate station system? This system seems to have been forgotten.

Mr. Slaby has built at Oberspree, near Berlin, for the A. E. G., a specially powerful station, similar to the one at Poldhu, and in which he has used alternating currents and commercial transformers. The device (Fig. 11) is as follows:

A condenser, K, is connected in a short circuit from the secondary of a commercial transformer and so chosen as to be capable of setting up a resonance from the secondary circuit. The condenser is discharged through an oscillator, C. The antenna, A, is run to earth direct and is simply connected to the oscillating circuit by a connection, L. It consequently forms part of the vibratory movement,

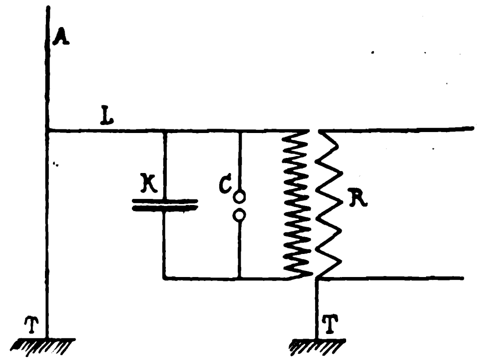

Fig. 11.

but, as M. Ferrie remarks, it is difficult to conceive, in the absence of more precise data, how the output could be desirable. In fact it seems improbable that the antenna should utilize a substantial portion of the energy from the exciting circuit. Furthermore, we are not acquainted with the results obtained with this apparatus.

Relative to installing an extra powerful station with this device, we would state from the start, that even though energy should reach the antenna, that the greater part of the energy must necessarily be lost in the circuit formed, while that portion which reaches the derived circuit would be divided between the earth and

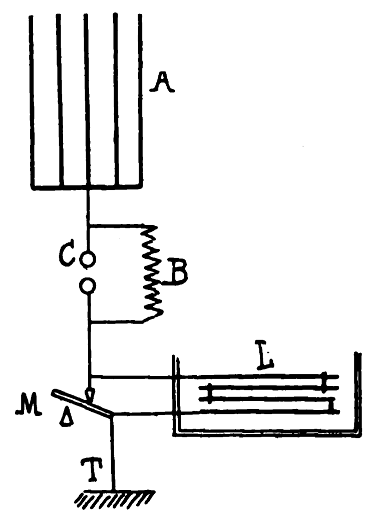

Fig. 12.

the antenna. On the other hand, Mr. Slaby positively states, as one of the great advantages of such a device, that the contact with the antenna is free from danger, since the latter is grounded and offers a free track for atmospheric discharges.

After some remarks devoted to the

proposition of Mr. Cooper-Hewitt relative to the utilization of the property of mercury arcs for furnishing slowed-down oscillations and regarding devices proposed by M. de Valbreuze, M. Ferrie took up the Fessenden transmitter, which he considered as being based on a new theory which is "quite mysterious." The antenna, A, is excited directly by an inductive coil, B, which has an oscillator, C (Fig. 12). The spark being permanent the transmission results from a suppression of the short circuit through the plates, L, by means of the key, M, M. Ferrie considers it difficult to understand the advantages which such a device may present, since the antenna vibrates generally in quarter wave, whatever may be the point where the oscillator is inserted. The manipulation of the key, M, would consequently have no other effect than that of changing the period of the oscillations produced.

It appears to us to be pertinent to remark here that since syntony allows of a much greater transmission distance through the better utilization of the energy, it is clear that if the receiver is placed near the limit of reception it will not receive, except when it is in harmony, i. e., when by manipulating the key the short circuit harmonizing device is suppressed. It is also to be noted that for the same reasons the Fessenden apparatus is useless on the sea, since in this instance the distances between the stations are always variable. On the other hand, the continuous operation of the transmitter has the great advantage in allowing of considerable increase in the speed of transmission, especially in powerful stations, and there is no moving interruption or loss of time in setting up a current in the primary. The time constants in wireless telegraphy, as well as with telegraphy by wire, depends on the capacity and the self-induction of the circuit.

(*To be continued.*)

ELECTRICAL EQUIPMENT OF A CANAL.*

BY F. H. LEONARD, JR.

The electrical equipment for the Cornwall Canal in Canada is supplied with current from a power house near Mille Roches on the canal. There are 225 arc lights located along the bank. A three-panel switchboard controls the operation of these lamps and each circuit is regulated by a 100 light regulator capable of maintaining practically constant current with any number of lamps in circuit from 1 to 100—its full capacity. The current for these circuits is stepped up from 2,200 volts by means of transformers of 60 kw. each—the transformers being provided with intermediate taps so that besides the full voltage of 11,000 volts, if a smaller number of lamps are required, either 4,400 or 6,600 volts can be used, thus reducing the reactance necessary to maintain a proper voltage and permitting of a higher P. F. under the conditions of partial load.

Current for the power circuits, three in number, is obtained by stepping up from the generating voltage to 11,000 volts by means of three 150 kw. transformers which supply the three-phase transmission lines reaching various locks along the 11 miles of canal. The primaries of both arc lighting and power transformers are controlled by oil switches connected to the bus bars on the main switchboard, a separate panel being provided for each class of service. The power circuits are passed through a separate high potential switchboard which connects the transformers to the three separate three-phase power lines. A 2,200 volt line also provides Mille Roches with light and power service.

The pole lines for the lighting and power circuits are of substantial structure, an exceedingly straight lot of cedar poles being used. These range from 30 to 50 feet in height, none having less than 7 inch tops, on which are mounted special cross-arms provided with hickory pins which were boiled in steric acid, 5½ inch triple petticoat glass insulators being used with satisfactory results with the 10,000 volt circuits. Bare copper conductor is used spaced 16 inches on centers, and on account of the low current per line no attempt was made to use the triangular arrangement of conductors, the three wires of each circuit being arranged side by side without transposition.

The three-phase power circuits occupy the upper arms and on the lower arms are located the single-phase arc circuits. The main lines occupy the south bank of the canal. Crossings are made at the Mille Roches bridge in armored paper cables, one for three-phase 2,200 volt power and lighting circuits and another for the single-phase 11,000 volt arc circuit. Another crossing is made at lock 18, which provides for three-phase power circuit, as well as another 11,000 volt arc circuit to provide for power and lighting on the north bank below this point. At the Stormont bridge, near Cornwall, another 11,000 volt arc cable provides for lighting the two piers at the bridge and an emergency cable is laid just above lock 17 so that in case of accident to any of the other crossings or a break in the line, emergency connection can be made in the houses covering the cable heads on the bank of the canal.

LIGHTING.

The lighting of the canal is carried out in a very liberal manner, an arc lamp being located on every fourth pole and the poles averaging about 100 feet apart. At the locks as many as 12 or 14 lamps are located so as to brilliantly illuminate both ends of the locks, as well as the intervening space and the regulating weirs, most of which are located beside the locks.

The lamps are hung from iron pipe brackets which pass through the pole and are held in place by a collar at the front side and a lock nut at the back and braced on the under side by an iron pipe strut fastened to the face of the pole by two lag screws. An insulated hanger is used at the outer end of the bracket (2 feet and 6 inches from the pole), which, together with the insulators on the lamps, renders danger from grounding in the lamp frame and bracket extremely remote. The lamps are trimmed from the pole without lowering; pole steps are driven in each lamp pole.

At the lower end of the canal, where three sets of locks are grouped together, the illumination is very brilliant, and viewed from the Stormont bridge at Cornwall—taking in at a single glance some 60 arc lamps reflected in the still waters of the canal—the sight is most impressive in its quiet brilliancy. The illumination of the locks is so much alike that a description of one will convey a very clear idea of them all.

A light is located at the piers as the lock is approached from below and an arc lamp is also located at each side of the lock just below the gate; two more lamps are located at the middle of each lock and two at the upper end of the lock just at the lock gates. There are also two more at the upper piers, and as two locks are located side by side, you can imagine that the illumination would almost rival daylight.

The upper level broadens into a lake of considerable proportions, about 30 feet deep near the lower end. The dam retains the water between Shieks Island and the Canadian shore, making a broad and easy navigable waterway of about three miles to the upper dam. The lamps are here less frequently located on the prominent points on the south side until the upper dam is reached, when the canal again narrows to the usual dimensions. The lamps are again located about 400 feet apart on the south bank up to lock 21,

*Abstract of paper read before the Electrical Section of the Canadian Society of Civil Engineers, Montreal.

which is a guard lock, there being very little difference between the upper canal level and the St. Lawrence River at this point. On the long pier on the south side protecting the canal entrance lamps are placed, as well as on the north bank as far up as Dickinson's Landing.

An illumination so perfect as above described, you can readily imagine makes navigation at night as easy as in daylight, and lockages are performed as rapidly and as easily as they could be in day time.

(To be continued.)

National Electric Light Association Convention.

Editor ELECTRICITY.

SIR: The programme for the 27th Convention of the National Electric Light Association is rapidly taking definite shape. Papers and reports already in press are as follows:

"Wrinkles," edited by Charles H. Williams of Madison, Wis.; Report on District Heating, E. F. McCabe, chairman; Report on Purchased Electric Power in Factories, W. H. Atkins, chairman; Report on Advertising, La Rue Vredenburgh, reporter; Report on Decorative and Sign Lighting, Arthur Williams, reporter; papers entitled "The Sale of Electrical Energy," by W. F. White; "Practical Notes on Steam Turbines," by Francis Hodgkinson; "A One Hundred Mile Transmission Line," by Robert Howes; "Economy Test of 5,500 Horse Power Engine and Generator," by Messrs. J. D. Andrew and W. F. Wells; "The Remote Control of Electrical Apparatus," by W. H. Cole.

It has been decided to hold the meeting for four days, the last day to be reserved for entertaining and sightseeing in Boston and vicinity, full particulars of which will be announced soon.

ERNEST H. DAVIS, Secretary.

About Graphite Brushes.

Imperfect commutation and its accompanying sparking is an evil that never grows anything but worse.

Copper brushes are much more prone to cause this than carbon, and carbon than graphite, simply because graphite brushes offer a higher resistance to self-induced, back currents in the coils, at the moment of commutation.

If graphite brushes are made of pure material and have sufficient contact area, they will reduce sparking to its minimum and will entirely stop any increase due to increasing roughness of wearing segments.

Graphite, from its peculiar nature, puts a smooth surface and high polish on the commutator without the employment of any lubricants or "compounds," and will not cause any appreciable wear, even after long periods of steady use.

In our engine room is a 100 kw. unit that has run steadily for three years at 250 r.p.m., and 10 hours a day, and its commutator is glassy-smooth, cool, and the wear scarcely detectable after this steady service.

The greatly increased and rapidly increasing sales of Dixon's Graphite Brushes bear strong witness to their superiority, on every count, to the cheaper gritty carbon so recently thought indespensable.

G. P. H.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 19, 1904

Electric Railways and Appliances.

757,471. Traction-Band for Wheels. Le Grand Kniffen, Chicago, Ill. Filed Sept. 28, 1903.

757,537. Method of Signaling for Electric Railways. Samuel M. Young, New York City. Filed Nov. 6, 1903.

757,630. Safety Device for Trolley-Poles. Phelam McCullough, Thomas Blaney and Robert Baron, Liverpool, Eng. Filed Jan. 22, 1901.

757,635. Tread for Traction-Wheels. John W. Pridmore, Chicago, Ill., assignor to the International Harvester Company, same place. Filed Aug. 16, 1902.

757,650. Means for Cleaning the Third Rails of Electrical Railways. Wilfrid Chausse, New York City. Filed Sept. 30, 1903.

757,692. Block-System Emergency Apparatus. Frederick V. Thompson, Philadelphia, Pa., assignor of one-half to Frank Baker, same place. Filed Jan. 10, 1903.

757,746. Car-Fender. Harry Howe, Toledo, O. Filed Dec. 10, 1903.

757,845. Car-Fender. Earl Sherwood, Honesdale, Pa. Filed Aug. 22, 1903.

757,906. Electric Railway. George H. Fretts, Springfield, Mass. Filed July 14, 1903.

757,985, Traction-Engine. Frank C. Watson, Des Moines, Ia., assignor to the Avery Manufacturing Company, Peoria, Ill. Filed Aug. 6, 1902.

757,564. Electric Headlight. William H. Northall, Elwood, Ind Filed March 20, 1903.

757,659. Electric-Arc Lamp. Robert Hopfelt, Berlin, Germany. Filed May 13, 1902.

757,695. Electric Lighting and Power System, William A. Turbayne, Buffalo, N. Y., assignor to Charles M. Gould, New York City. Filed Jan. 13, 1902. Renewed Sept. 29, 1903.

757,782. Electric Arc-Rupturing Device. Sidney H. Short, London, Eng., assignor to the Westinghouse Electric & Manufacturing Company. Filed Feb. 11, 1902.

757,847. Electric-Arc Lamp. Frederik Sindingchristensen, New York City, assignor, by direct and mesne assignments, to the Commercial Construction Company, same place, and William H. Locke, Jr. Filed May 4, 1903.

757,958. Electric-Arc Lamp. Isaac W. Percival, St. Louis, Mo., assignor, by mesne assignments, to the Westinghouse Electric & Manufacturing Company. Filed Jan. 23, 1899.

Electrical Machinery and Apparatus

757,436. Electrical Generating System. William A. Bole, Pittsburg, Pa., assignor to the Westinghouse Machine Company. Filed July 12, 1901.

757,439. Prepayment Electrical Measuring Instrument. Frank Conrad, Edgewood Park, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed June 24, 1903.

757,515-516-517-518. Phase Regulation, Phase-Angle-Adjusting Means and Method of Phase-Angle Adjustment. Egbert M. Tingley, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Original application filed May 9, 1896. Divided and last application filed Feb. 4, 1901.

757,523-524-525. Induction-Coil. Richard Varley, Providence, R. I., assignor to the Varley, Duplex Magnet Company. Filed Dec. 14, 1903; Dec. 30, 1903, and Jan. 12, 1904.

757,527. Vibrator for Induction-Coils. Richard Varley, Providence, R. I., assignor to the Varley Duplex Magnet Company. Filed Jan. 20, 1904.

757,765. Insulator. John W. Osborne, Winchester, Ill. Filed Aug. 15, 1903.

757,853. Electric Switch. George H. Whittingham, New York City, assignor to the Automatic Switch Company of Baltimore City. Filed Oct. 29, 1903.

757,880. Electric Rheostat. Roy W. Brown, Amsterdam, N. Y. Filed April 21, 1903.

757,898. Electric Controller. Arthur C. Eastwood, Cleveland, O. Filed Jan. 30, 1904.

757,925. Electric Switch. Charles F. Hopewell, Cambridge, Mass., assignor to the Uni Signal Company. Filed Oct. 7, 1903.

Telephones and Telephone Apparatus.

757,609. Electrical Telephone Apparatus. Pliny H. Fisk, Clay, Ia. Filed June 13, 1903.

757,799. Telephone Transmitter. Walter L. Wilhelm, Buffalo, N. Y., assignor to the Wilhelm Telephone Manufacturing Company, same place. Filed Jan. 23, 1902.

757,826. Telephony. Albert Meinema, Chicago, Ill. Filed Jan. 16, 1904.

757,850. Antiseptic Attachment for Telephones. Hugh L. Thompson, Waterbury, Conn. Filed March 1. 1904.

758,031. Telephone Desk Set. Henry P. Clausen, Chicago, Ill., assignor to the American Electric Telephone Company. Filed May 26, 1902.

Miscellaneous.

757,446. Secondary Battery. Louis H. Flanders, Wilkinsburg, Pa., assignor to the Westinghouse Machine Company. Filed July 10, 1903

757,495. Electric-Sole Shoe. Adam Reed, St. Joseph, Mo. Filed Feb. 4, 1904.

757,503-757,504 Telegraph System. Harry O. Rugh, Chicago, Ill., assignor to the Western Telegraphone Company. Filed Aug. 31, 1903.

757,505. Telegraphy. Harry O. Rugh, Chicago, Ill., assignor to the Western Telegraphone Company. Filed Aug. 31, 1903.

757,557. Electrolytic Deposition Apparatus. William J. Jory and Joseph H. Jory, San Francisco, Cal. Filed April 7, 1903.

757,559. Wireless Telegraph System. Guglielmo Marconi, London, Eng., assignor to the Marconi's Wireless Telegraph Company, Limited. Filed Nov 19, 1901.

757,603. Mechanism for Holding Electrotype Plates. Charles W. Eberhard, Chicago, Ill. Filed June 30, 1903.

757,618-757,619-757,620. Process and Method of Electric Heating. William S. Horry, Niagara Falls, N. Y., assignor to the Union Carbide Company, same place. Filed April 5, 1902; filed April 28, 1902; filed June 6, 1902.

757,621. Electric Furnace. William S. Horry and Edgar F. Price, Niagara Falls, N. Y., assignors to the Union Carbide Company, same place. Filed Oct. 11, 1902.

757,633. Electric Heating. Edgar F. Price, Niagara Falls, N. Y., assignor to the Union Carbide Company, same place. Filed April 5, 1902.

757,634. Electric-Resistance Furnace. Edgar F. Price, Niagara Falls, N. Y., assignor to the Union Carbide Company, same place. Filed April 30, 1903.

757,670. Electrically-Heated Soldering-Iron. Alfred C. McCloskey, Philadelphia, Pa. Filed May 6, 1903.

757,722. Electric Semaphore. Dona Boisvert, Providence, R. I, Filed Oct. 13, 1902.

757,736. Multiplex Telegraphy. John J. Ghegan, Newark, N. J. Filed July 3, 1902.

757,768. Signal Apparatus. Jonathan D. Price, Aurora, Ill., assignor to the Miller Signal Company, Chicago, Ill. Filed Jan. 21, 1902.

757,773. Electric Fan. Frank N. Roehrich, Brooklyn, N. Y. Filed Dec. 10, 1901.

757,817. Process of Electrolytically Extracting Copper and Zinc from Ores. Stanislaw Laszczynski, Kielce, Russia. Filed Oct. 10, 1902.

757,943. Storage Battery. Abraham V. Meserole, New York City. Filed July 13, 1903.

758,004. Device for Wireless Telegraphy. John A. Fleming, London, Eng., assignor to the Marconi's Wireless Telegraph Company, Limited. Filed April 8, 1901.

758,005. Apparatus Employed in Wireless Telegraphy. John A. Fleming, London, Eng., assignor to the Marconi's Wireless Telegraph Company, Limited. Original application filed April 8, 1901. Divided and this application filed Nov. 9, 1901.

758,006. Wireless Telegraphy. Francis J. Green, Detroit, Mich., assignor to the American Engineering Company, Detroit, Mich. Filed Jan. 9, 1903.

THE TELEPHONE WORLD.

Telephone War in Independence, Mo.

The telephone fight in Independence is raging hot and furious, as much so as in Kansas City. The greater portion of the merchants have decided to use one 'phone and concluded to disconnect the Bell 'phone on May 1, and have given public notice to that effect. There will be some of the merchants who will use both 'phones, and so the fight goes on merrily. The Bell and the Home have about the same number of subscribers in Independence, and the notice was given so that the residents of the town could take up the matter and dispose of it to suit themselves.

Reorganization of Independent Company in Iowa.

The E. H. Martin Telephone Company of Webster City will reorganize with a capital stock of $300,000, retaining its present headquarters in that city. This company owns and operates the Postal Telegraph lines in that section of the State, as well as leases to other parties nearly 1,000 miles of telegraph lines. The Martin Company is one of the strongest Independent telephone companies in the State, covering eight counties.

J. M. Oliver, of Orlando, Fla., says that he is making arrangements to build a telephone line from Jacksonville to Tampa, and expects to include Bartow, by building a line from there to Bartow Junction. The enterprise is to be known as the Florida Co-operative Telegraph & Telephone Company, and it is to be incorporated at $100,000, 75 per cent. of which he and his family will subscribe for. The remaining $25,000 will be issued in co-operative stock, at $100 per share, and he desires to place this at different points along the line. He expects to begin active operations by May 15, and will have about 300 men, divided into eight gangs, working from Jacksonville, Orlando, Bartow, Tampa and other points in every direction where it is determined to build the telephone line.

The Eldon, Ia., Independent Telephone Company, with about 250 miles of lines through Wapello, Davis, Jefferson and Van Buren Counties, has been sold to Clyde A. Mann, of Sioux City. It is understood Mr. Mann has completed arrangements by which a Cedar Rapids company will look over the properties of the Eldon company.

The Phoenixville Pa., Telephone Company was lately organized and a temporary organization effected by the election of nine directors and the adoption of a constitution and by-laws. The directors will select from their number a president, secretary and treasurer.

Men engaged in the electrical and telephone business in North Dakota are to hold a convention at Grand Forks, May 11 and 12, for the purpose of forming a State organization.

The Warwick, N. Y., Telephone Company has announced an increase of 50 per cent. in rates, to become operative July 1.

The Campus, Ill., Telephone Company, capitalized at $2,500, was recently formed.

Pennsylvania Company Reorganized.

Messrs. Charles West, W. G. Harding and associates, of Wilkes-Barre, have recently purchased the Citizens' Telephone Company of Honesdale. The Citizens' Telephone, is an Independent company in opposition to the Bell Company. It has been reorganized under the name of the Honesdale Telephone Company with a capital of $40,000. It now has 250 local telephones. The new management already have contracts for 100 additional 'phones which will be installed immediately. A long-distance line will be built to Carbondale which will give the company's patrons long-distance connections with all the extensive territory covered by the Consolidated Telephone Companies of Pennsylvania, and through its allied companies with towns and cities in New Jersey, New York and Pennsylvania.

Farmers of Montgomery County, Ala., are determined to secure a telephone system connecting the rural homes. At a recent well-attended meeting of the Montgomery Agricultural Association the executive committee was authorized to canvass the farmers of the county and ascertain how many of them would contract for telephone service.

Telephone lines on the two principal roads to the south and east of Holley, N. Y., are now practically assured. Two years ago a line was built on the Holley road as far as Clarendon. This line will now be continued about four miles farther to Honest Hill. A line also will be built, according to the plans, along the main road to Bennetts Corners, and from there south a distance of seven miles.

Arthur G. Dickson, of Philadelphia, Pa., special master, appointed by the United States Circuit Court in Easton, Pa., sold the lines and system of the New Jersey & Pennsylvania Telephone Company to J. Davis Broadhead, of South Bethlehem, attorney for the bondholders, for $25,000. The lines are operated extensively through that section.

After years of patient waiting, Red Creek, N. Y., was recently admitted to the telephone world, and placed on the map. A deal was closed which means much to Wayne County as well as the immediate vicinity.

The Inter Ocean Telegraph & Telephone Company has about 2½ miles of cable in Fairport, N. Y., ready to string for its exchange as soon as the village authorities and the company decide on the location of poles.

The Syracuse, N. Y., Telephone Company, of which J. J. Jermyn is president, has in mind an automatic system for that city, and with this end in view systems of that character will be inspected in other cities.

The Waterbury, Conn., Automatic Telephone Company has filed with the Secretary of State a certificate of increase of capital stock from $10,000 to $50,000.

The Gayes Mutual Telephone Company of Mattoon, Ill., has increased its capital from $2,400 to $4,980.

Underground Wires for Clarion, Ia., Company.

The Clarion & Northwestern Telephone Company is making arrangements to place all the wires in the business section of the city underground, and it is expected that if the experiment proves successful the entire system of wires will be thus placed. There is no city ordinance requiring underground wires, but the directors of the company state that they believe this the only satisfactory method, as their loss in times past from storms has been considerable. The company will expend about $1,500 in purchasing cable and other supplies needed for the change to an underground system, and work will commence as soon as the weather permits.

Telephone Improvements in Maine.

The success of the Northeastern Telephone Company in securing permits to enter Lewiston and Auburn has set the New England Company to thinking about increasing its facilities and improving its service in other cities. In Augusta the business has developed to such an extent and the number of subscribers has increased so rapidly, that the present accommodations of the operating room and central office over the Maine Central station are entirely inadequate, and it is the intention of the company to erect a new and commodious building that will improve the service and meet all the requirements of the public.

Another telephone line between West Exeter and West Winfield, N. Y., will be put up as soon as the season will permit. It will be known as the Twentieth Century Line.

The new building of the Vermilion County Telephone Company, to be erected in Danville, Ill., will cost $16,000.

The Dewitt, Neb., Telephone Company has filed notice of an increase in its capital stock from $10,000 to $20,000.

A new telephone line has just been completed and put in operation between Terrell and McCoy, Tex.

The street telephones, operated in connection with the Wisconsin Telephone Company's system in Milwaukee, have proven a success.

The Green Spring Telephone & Electric Company of Green Spring, O., has increased its capital stock from $20,000 to $35,000.

The Canotton Valley Telephone Company of Jewett, O., has increased its capital stock from $2,000 to $9,000.

Telephone Incorporations.

The Fountain Creek Telephone Company, East Lynn, Ill. Capital stock, $34,000, Incorporators: W. A. Yeasel, G. H. Wieland and H. C. Tucker.

The Farmers & Merchants' Telephone Company Arlington, Minn. Capital stock, $10,000. Incorporators; Adam C. Buck, Henderson; John Young, Frank F. Mansfield, Albert Zimmerman, Theodore Streissguth, Vincent F. Schmoll Henry Hillemann and August C. Maillin of Arlington.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Belle Fourche, S. D.—C. H. Williams, an electrical engineer of Deadwood, is making an effort to organize a company to erect an electric lighting plant. Plans have been drawn for the building of a plant to cost $8,000.

Bloomingdale, Mich.—The people here are agitating the subject of electric lights.

Bottineau, N. D.—The power house of the electric light plant was lately destroyed by fire.

Broxton, Ga.—Local capitalists are going to establish an electric light plant here.

Burgaw, N. C.—John W. Reilly, of the firm of J. W. Reilly & Son, of Wilmington, will confer with parties here relative to the installation of an electric lighting plant.

Castledale, Utah.—W. E. Raines, engineer of Salt Lake City, will submit the estimated cost of the proposed electric light plant to the boards of Orangeville and this town. A. C. Van Buren is president of the Orangeville board.

Central City, Kan.—C. H. Blandford, city clerk, states that an electric light plant for this place is being contemplated.

Citronelle, Ala.—It is reported that an electric light plant and ice factory will be erected here. Address H. O. McMair, cashier of the First National Bank.

Clarksville, Ark.—The city council has granted Col. E. T. McConnell, a resident capitalist, a 30-year franchise for an electric light plant. Work on the plant is to be commenced at once.

Columbus, Neb.—H. H. Childs, representing an Omaha electrical supply house, has submitted a proposition to the council to install an electric lighting plant at the waterworks station at a cost of $4,000 to $5,000, which will be considered.

Dover, Del.—The proposition to borrow $6,500 for the improvement of the electric light plant is being discussed.

Eaton Rapids, Mich.—The citizens have voted to bond for $12,000 to purchase the electric light plant of this city.

Eureka, Cal.—Robert M. Pringle, supervisor of engineering, or John Charles, supervisor of construction, will make necessary plans for installing an electric light plant at Hoopa Reservation.

Farmer, N. Y.—This village is soon to have electric lights,

Flora, Ind.—It is reported that $28,000 will be spent on the construction of an electric light and waterworks plant.

Garrison, Ia.—The matter of securing an electric light plant is under consideration.

Hannibal, Mo.—William O. Webster, of 2949 LaClese avenue, East St. Louis, Ill., is interested in the electric light and power plant projects here, and will have charge of all arrangements. Work is to be started by May 1.

Hattiesburg, Miss.—An ordinance was lately passed by the board of aldermen authorizing the issuance of $60,000 bonds to build or buy a complete electric light plant.

Hooper, Neb.—The Hooper electric light plant was recently damaged by fire. The dynamo is almost a complete loss. Mr. Martin, proprietor, carried $1,500 insurance, which will not cover thel oss.

Huntington, Ind.—Roanoke is about to make arrangements with the Ft. Wayne & Southwestern Traction Company, whose power house is in this city, for electric lighting for streets and business blocks.

Ipswich, Mass.—The city council has appointed a committee of five to look after the electric lighting system, and see about extensions and other matters pertaining to the lighting of this city,

Lewiston, Pa.—The contract for street lighting has been awarded to the Lewiston Electric Light Company at $65 per light.

Moberly, Mo.—The Moberly Light, Power & Fuel Company has been granted the right to construct, maintain and operate an electric and gas light, power and fuel plant here.

Mooresville, N. C.—C. V. Vails states that electric lights are under consideration.

New Athens, Ill.—An electric light plant is to be built here.

New Harmony, Ind.—George C. Morgan, C.E., 169 Jackson Boulevard, Chicago, is reported to be preparing plans and specifications for an electric light plant for this city.

Santa Barbara, Cal.—A new gas and electric light plant is planned, for which $50,000 has been subscribed. The promoters expect to soon have $200,000, the amount necessary with which to begin the work. The council will be asked to grant a franchise to the new company.

Vancouver, B. C.—The department of the Columbia has decided to adopt electric lights. The barracks have heretofore been lighted with kerosene. The system has given much dissatisfaction. The new contract will amount to several thousand dollars annually.

Viola, Ill.—The electric light question is being discussed here.

Waverly, Tenn.—It is reported that J. J. Jones will improve the Waverly Electric Light Company's plant.

Wilton, Ia.—George Bennick, mayor, has called a special election for May 2 to vote on the question of issuing additional bonds for improving the electric light plant and waterworks system.

Youngstown, O.—G. E. Turner and others are organizing a company, it is stated, to build an electric light and power plant, to cost about $30,000.

STREET RAILWAYS.

Coalgate, I. T.—C. W. Copeland, of the Lehigh Traction Company, states that the construction of a trolley line between here and Lehigh is a certainty.

Fort Collins, Col.—W. O. Mossman has secured a franchise from Larimer County, giving him a right of way for an electric railway leading from a point 20 miles northwest of here to North Park. He must file maps of the route selected with the county clerk on or before April 30, 1905, and within 10 years thereafter an electric railway must be in operation.

Minneapolis, Minn.—The Minneapolis-Champlain & Bloomington Electric Company proposes to extend its lines.

Missouri Valley, Ia.—Capitalists have been here who, it is said, have plans on foot whereby this place will be connected with the Illinois Central by an electric road.

Niagara Falls, N. Y.—A franchise for a cross town electric railway through this city has been granted the Electric Railway Company.

Pavilion, N.Y.—The Buffalo & Depew Electric Railroad Company proposes to build an electric line to Oatka Valley.

Philadelphia, Pa.—About 25 miles of new line will be added this year to the Philadelphia Rapid Transit Railway system, which will be extended in many directions.

South M'Alester, I. T.—A movement is on foot to incorporate an electric line extending from here to Oklahoma City via Lehigh, Coalgate and Shawnee. The line will be over 200 miles long, and will handle passengers, freight and express business.

Syracuse, N. Y.—Manager Connette, of the Rapid Transit Company, states that the company is trying to secure right of way to North Syracuse.

Trenton, N. J.—The Vandegrift Construction Company proposes to build a new trolley system between this city and New Brunswick.

West Chester, Pa.—H. H. Hoch, of New York, is the prime mover in the construction of a trolley line between this place and Wilmington.—Mr. Schamberg proposes to build a new trolley system here to cost $600,000.

Winder, Ga.—The electric car line which is now being planned from Anderson, S. C., via Hartwell, Commerce, Jefferson, Winder and Logansville to Atlanta, is in charge of the Georgia Traction Company. The line will be used both for passenger and freight transportation. Local towns along the line are asked to subscribe enough stock to grade the roadbed.

BIDS WANTED.

Black Diamond, Cal.—Bids are asked by T. M. Donovan, town clerk, until May 17, for a franchise authorizing the construction of poles on the streets of this place, for carrying wires to transmit electric heat and power, as applied for by the Redwood Manufacturers' Company.

Delaware City, Del.—Sealed proposals in triplicate, for constructing, plumbing, heating and electric wiring 12 bed hospital at Fort Mott, N. J., will be received until 11 A.M., May 16. U. S. reserves right to reject or accept any or all bids. Information furnished by Louis F. Garrard, Jr., Capt.,Q. M. Department, of this city.

Manitowoc, Wis.—The William Rahr Sons Company will install two electric generators of 250 and 100 kw. capacity respectively, in their malting plant here; and also 25 electric motors, ranging in power from 1 to 50 hp., for which bids will be received. Reinhardt Rahr is secretary and treasurer.

New Freedom, Pa.—Bids will be received until April 30 for the construction of an electric lighting plant. Address W. H. Lowe, secretary.

Traverse City, Mich.—Sealed bids will be received until May 31, for the lighting of the streets of this city for a period of five years from the 1st day of May, 1905. Address Charles M. Beers, city clerk.

Wittenberg, Wis.—Sealed bids for the construction and installation of an electric light plant here will be received until May 9 by John England, village clerk.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 13⅛@13¼c.; Lake 13¼@13⅜c.; casting, 13@13⅛c.

The stockholders of the Interborough Rapid Transit Company of New York will hold their annual meeting on May 11.

Directors of the Cincinnati Gas & Electric Company have increased the dividend one-half of 1 per cent., to 4½ per cent. per annum.

President Herbert Lloyd says the Pennsylvania Electric Vehicle Company is earning its expenses and several thousands a year in addition.

The directors of the Automatic Electric Company, Chicago, have declared the regular quarterly dividend of 2 per cent. payable May 2.

Directors of the Philadelphia Electric Company re-elected the old officers, but took no action on the proposed assessment on the stock.

The directors of the Cambridge (Mass.) Electric Light Company issue a circular to stockholders offering for subscription 1,000 shares of new stock at $140 a share.

National Carbon Company directors have declared a regular quarterly dividend of 1¾ per cent. on the preferred stock, payable May 14. Books close May 2 and reopen May 16.

Negotiations are in progress looking toward a combination of the Rochester (N. Y.) Gas & Electric Company, the Rochester Light & Power Company and the Rochester Railway Company.

Blair & Co. of New York are offering at private sale $10,000,000 of the 5 per cent. profit-sharing notes of the London Underground Electric Railway Company. The notes are offered at 96½ and interest.

Official announcement was made Friday that the Allis-Chalmers Company has decided to suspend dividends on the preferred stock. It was stated that the management does not purpose to pay dividends unless they are earned.

A man prominent in the heavy machinery trade, and whose opinions are sought after, says: "I am looking for an interesting fight between the General Electric and Westinghouse companies and the Allis-Chalmers Company for heavy electrical machinery."

It is said in Wall Street that the Metropolitan Securities Company of New York will soon avail itself of its right to issue $2,500,000 Central Crosstown bonds and $2,000,000 Third Avenue 4s for improvements. It is said that funds will be provided in that way instead of making a further assessment on the Metropolitan Securities stock.

An official of the Brooklyn Rapid Transit Company says: "Our earnings continue to grow and our summer business will be a record-breaker. B. R. T. is developing into the great property it was planned to be, and all it asks is to be let alone. It has been a Wall Street football long enough. Wall Street is not a healthy atmosphere to develop a business property."

According to the Boston *News Bureau* a General Electric interest says: "It is no use crying over spilled milk, but as a matter of fact we believe that if we had let the Stanley Electric Company alone for three months longer it would have gone into the hands of a receiver. We paid for it four times what it was worth, but owing to the exigencies of the case we necessarily had to buy this company somewhat on faith and upon the representations made to us, without making an examination such as would ordinarily have been done."

EDITORIAL NOTES.

Electricity, of Course.

The World's Fair at St. Louis was opened on Saturday by President Roosevelt, in Washington, who touched a gold key which completed the electrical circuit and released the gigantic power of the great Exposition, putting in motion the 40,000 horse power machinery and the fairy-like cascades on the grounds.

Press dispatches assure us that the electrical display "could not be surpassed," which is a beautiful tribute to Prof. Goldsborough and his assistants, who will receive their just meed of praise when the electricians assemble in St. Louis.

* * *

General Electric's Annual Report.

The directors of the General Electric Company, in their annual report to the stockholders, state that the report shows net profits of $7,865,376, including royalties and profit from securities sold and after allowing for depreciation. From this amount was deducted $76,007 for interest on debentures and $1,470,098, representing the amount written off from the patents and other accounts of the Stanley Electric Company, leaving a balance of $6,319,270. The dividends paid during the year were $3,508,284, and the surplus as of December 31 last, including the amount carried over from the previous year, was $7,263,688.

On the general conditions governing the company's business, the report says:

"The disturbed financial and other unsatisfactory conditions of the past year have considerably affected your business and the percentage of profit upon business done is smaller than for the previous year; the increased price of copper, higher priced and less effective labor, large expenses in developing steam turbines, and lower selling prices have all contributed to this result."

Considerable attention is given in the report to the advantages of electricity as a motive power on railroads as compared with steam, and the interesting claim is advanced that "the popular apprehension of the 'deadly third rail,' is without foundation as regards danger to the public—there is not a recorded instance of a passenger being killed by the third rail. The reduction in the operating expenses of the Manhattan Elevated from 55.8 per cent. in 1901, when steam was in use, to 44.7 per cent. in 1903, when the motive power was electricity, is instanced as a proof of the saving secured by a change from steam to electricity. Referring to the order secured some months ago from the New York Central for 30 electric locomotives. Third Vice-President E. W. Rice says:

"We believe this order is the forerunner of many others to be placed by steam railroads."

Rapid Transit Questions.

Full details regarding the route of the new rapid transit subway for Greater New York was laid before the Rapid Transit Commissioners last week. There will shortly be a public meeting to consider the proposed plans. It is suggested that the commission proceed as early as possible to let the contract for the South Brooklyn extension, the tunnel which is to run under Fourth avenue from the Flatbush terminal to Fort Hamilton. This tunnel, the Plan and Scope Committee suggests, can be built at the same time as the Manhattan tunnel, which is to be known as the east side extension.

Now that the commission has unlimited money to spend on rapid transit it believes that both tunnels can be constructed

at the same time. The Manhattan tunnel, it is estimated, will cost about $30,000,-000, while the Brooklyn tunnel will probably not cost more than $5,000,000 to construct.

Owing to the various conditions which must be complied with, the contract for either tunnel cannot be let until at least twelve months hence.

Meantime the commission will endeavor to have several amendments to the existing rapid transit law enacted by the Legislature. They will send bills to Albany next year empowering the city to lay conduits for pipes and wires in the tunnel, and will also have introduced a measure allowing the tunnel franchise to be taxed.

Another change advocated by one of the city officials is to build the station entrances along the line of the new tunnel on private property, which is to be taken by the city for the purpose, instead of on the sidewalks.

It is sincerely to be hoped that next year the necessary legislation may be obtained for placing pipes and electric wires in the proposed tunnels. As things now are a street is no sooner made attractive than it has to be opened up to repair either a pipe or a cable conduit. This probably helps the laboring man but it certainly does not help the business enterprises that are unfortunate enough to be located along a defective pipe line. With the pipes and cables in the subway all such nuisances would be done away with.

The citizens of Manhattan will have to have a little more patience as regards the rapid transit system. It is announced that the opening has been deferred until September. The commissioners do not deem it good policy to have a formal opening of the road until it is ready for actual operation. The management of the road expects to run trains continuously beginning on the day after the formal opening.

* * *

A German Electric Railway's Earnings.

The official returns have just been issued relating to the working results for 1903 of the first electric railway which was established in Berlin, and the initial section of which was opened for traffic in February, 1902, the remaining sections being opened gradually in the same year. Thus the results for 1903, although showing satisfactory progress, are not strictly comparable to the incomplete period of nearly eleven months, during which only one portion of the railway was in operation. The line, which is known as the Elevated & Underground Electric Railway, carried 29,628,463 persons in 1903, as compared with 18,813,994 passengers in 1902, while the short level section associated with the undertaking transported an additional 2,507,649 persons, as against 1,227,010 in the preceding period. The total working receipts amounted to $954,515, and the expenses to $500,630. After providing for the interest on the bonds, which amounted to $1,950,000, and making provision for reserve and renewal funds, there remains a net profit of $287,615. It is proposed to pay a dividend at the rate of 3½ per cent. for the year on the share capital of $7,500,000. In the preceding year the railway was worked by the contractors, who guaranteed and paid 4 per cent, interest on the share capital for 1902, at the end of which the railway was transferred to the proprietary company.

Italy Needs Electrical Machinery.

Advices received by the Government at Washington are to the effect that there is room in Italy for the importation of American electrical machinery, in spite of the many existing local shops, and of the competition of Switzerland. The United States being, however, far ahead of any other country in the matter of inventions and labor-saving machinery, American machine manufacturers would undoubtedly be able to create a market in Italy for their productions, especially in the line of machinery in connection with the utilization of the great water power of Italy. Electrical traction is being developed considerably in all the provinces of Italy, as well as electric light, the use of which is constantly increasing. Electrical machinery to the value of $60,592 was shipped from the United States to Italy during the fiscal year 1903.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

R. A. Fliess, who has been associated with Mr. Edison in the development of the nickel-iron storage battery, gave a talk about this invention to the American Institute of Electrical Engineers on the evening of April 27. Mr. Fliess stated that a cell which had been run over 4,000 miles was carefully examined for any deposit of material that had been loosened from the plates. There was a perceptible, but small, amount. Mr. Fliess showed it in a bottle. When the 4,000 mile run was ended no deposit at all was found. This was a striking contrast to his observations on lead batteries. He had charged and discharged one of the latter 190 times in succession, in a laboratory, without putting it on the road in a vehicle, yet a considerable quantity of material settled in the bottom of the cells. This was exhibited to the audience. The Edison batteries just mentioned were used in automobiles on all kinds of roads, and at the end of the trials they not only were uninjured, but each had apparently a slightly greater capacity than before. "We have done our best to ruin these batteries," said Mr. Fliess, "but we have not succeeded yet."

The Canadian Electrical Association will hold its annual convention in Hamilton June 15, 16 and 17. A series of interesting papers has been arranged for.

A large deposit of molybdenum has been discovered on Badger Mountain, near Manitou, Col. The mineral is valued at $65 a pound, and is used chiefly in hardening plate.

General Greely, chief signal officer of the army, has decided to award the contract for the manufacture of about 625 miles of submarine cable to the Safety Insulated Wire & Cable Company of New York. This cable will be used to connect Sitka, Alaska, with Fort Liscum, near Valdez, on Prince William Sound. The cable will be shipped by rail from New York to Seattle, and will probably be laid during the coming summer.

In the laboratories of the National Bureau of Standards in the Palace of Electricity at the World's Fair at St. Louis are shown more than $50,000 worth of instruments for testing every kind of electrical machine and apparatus. Several Government experts are conducting tests and investigations in the exhibit space of 23 by 200 feet. In order to overcome the effect of warm weather on the instruments an expensive refrigerating plant will be installed, as warm weather produces a moist surface on the delicate instruments. The plant will dry the air. The testing instruments will be of use in making complete records and also for aiding juries in making their awards.

The New York State Civil Service Commission, among examinations to be held May 21, will include positions for electrical engineers in State hospitals and institutions. Application must be made to the chief examiner, C. S. Fowler, Albany, before May 16.

CENTRAL STATION ECONOMY.*

BY F. H. DAVIES.

When one considers that in the average well-managed electricity works only about one-twentieth of the heat energy liberated by the combustion of coal is delivered in the shape of electrical energy at the dynamo terminals, it is obvious that there is plenty of room for improvement in methods of generation. But practical experience shows that if this tremendous loss is to be reduced to any appreciable extent, these methods must be of an entirely new character, and must not require the present numerous transformations of energy that necessarily produce uneconomical results. This fact has been recognized for some time, and many efforts have been made to bring about a more satisfactory state of affairs by the production of electricity direct from coal, thus eliminating those factors that are responsible for the waste—viz., boilers, steam pipes, engines and dynamos. Whether this Utopian idea will ever take practical shape remains to be seen; at the present time the outlook is hardly hopeful, and we have no alternative but to proceed along the stereotyped, and from the point of view of transformation of energy, extremely inefficient lines.

There are, however, many little economies that may be effected in central station practice, which, although small in themselves, mount up considerably in the long run. The means of securing these economies will generally suggest themselves when it is ascertained where the loss is taking place, but in connection with this the chief thing is to know where to look for it. A case in point is that of wet coal. Very frequently, when coal is brought to the works by barge, it arrives in a more or less sodden state at the bottom of the load, and as this portion is naturally on top when stored into the bunkers, a great part of the water percolates into the heap and damps it right through, with the result that its efficiency as a heat producer is greatly diminished. It is astonishing what a long time a heap of damp small coal takes to dry even when exposed to sunshine or a high temperature, in the boiler house. The surface naturally dries quickly, but a few inches down moisture will be found even after weeks of storing in a dry place. The obvious remedy is continually turning the coal and spreading it over as large a surface as possible, but this necessitates bunkers of very ample proportions, such as are not usually found. The prevailing impression seems to be that coal can be stored anywhere and anyhow, and many do not appear to be alive to the fact that "weather" has a very bad effect on its calorific properties. The ideal coal bunker should be spacious and well ventilated, and, if possible, placed in such a position as to allow of a glass roof, and the consequent drying action of the sun. Coal stored in such bunkers has a fair chance of drying, that in the usual gloomy dungeon of the domestic coal-cellar variety it does not get. This seems but a small point, but it is one that should not be neglected, as those who have gone into the question practically well know. Of course, where coal is very small and dusty the addition of a little water is necessary, in order to keep it from being carried into the flues, unconsumed, by the draught.

Bad stoking is a very prolific source of waste, and whether it is performed by hand or machinery, there are few engineers who can be certain that they are getting the full value out of the coal consumed. It is well known, of course, that the grate should be uniformly covered, and only sufficient air admitted to insure perfect combustion and the minimum amount of smoke. It is, however, only too common to find bare patches on the bars, especially where mechanical stokers are used, or, rather, misused. With those of the coking type with movable grates, a common mistake in working is that of allowing the fuel to burn completely away before it reaches the back of the furnace, the consequence of which is that the hinder part of the bars are only covered with clinker, and so let through air in large quantities, thereby reducing the efficiency considerably. It is by far better practice to so adjust the speed of the bars that the fuel falls over the back partially consumed; it can always be burnt over again mixed with fresh coal, or if allowed to remain in the ash pit, will efficiently finish its combustion there. Another alternative is to work with a thicker fire, which naturally takes longer to burn away, but this course is not always possible, as the thickness of fire must to a certain extent depend upon the nature of the coal and conditions of load and draught. Good stoking is naturally the outcome of experience that dictates what must be done under varying conditions, and it must not be thought that even the best mechanical stoker can be efficiently worked by an unskilled man; if anything, the reverse is the case.

The banking of fires in standing boilers is another operation that frequently gives rise to loss, and in connection with this it is most essential that the coal should be well damped and heaped, and that the dampers should be efficient—that is to say, not leaky.

The brickwork settings of water-tube boilers need most careful erection and watching, as the air leakage that is continually taking place through the pores of the bricks and their joints is very deleterious to efficiency. The layers of fireclay mortar between the courses should be as thin as possible, and the bricks should always be of the glazed variety. Cracks, which are bound to occur in time, should be thoroughly stopped up directly they appear, and holes in the brickwork through which blow-down and other pipes emerge should be carefully filled up or covered, not with cement, as this is liable to cause damage to the pipes, but with a dab of boiler lagging or a wooden or iron cover. This trouble of air leakage is so serious and difficult to overcome that in places it has been found necessary to completely cover in the boiler and brickwork with a thin sheet-iron casing. Well-built glazed brickwork will, however, generally solve the problem, or where ordinary bricks are used, a good coating of tar will considerably reduce the leakage.

Perhaps the greatest source of waste in boiler-house plant is the old-fashioned steam feed pump that carries steam along the full length of the stroke. This fact has long been recognized, but, strange to say, this type of pump is still installed on the score of its supposed cheapness, which is an utter fallacy. The modern expansive steam-pump is very little, if any, dearer in first cost, and will certainly save the extra amount if it exists, in a few months in steam consumption alone, putting aside repairs and renewels, which are comparatively low in this type of pump. The so-called cheap pump is also frequently very wasteful on the water side, owing to its plunger letting by, thus producing a churning motion that absorbs a great deal of power. The water pistons of these pumps should be frequently examined, and if it is noticed that a higher speed than usual is necessary to perform the same work, they should be repacked at once, as this is a sure sign of letting by. Apropos of this, it is always advisable to thoroughly overhaul pumps of this kind before setting to work for the first time. In a station with which the writer was connected some cheap American feed pumps were installed. They were sent down as ready for running, and were started up hurriedly without examination. One of them answered satisfactorily for a year, and then gave signs of being unable to do its work. Upon overhauling it was found that the

*From the "Electrical Engineer," London.

water piston had never been packed; the space for the fibrous packing was empty, and the pump had been running, strange to say, satisfactorily on the two gunmetal ends of the plunger. This was doubtless due to a very exceptional piece of American workmanship, as at the start the piston itself had evidently been a perfect fit. The above is given as an instance of the care that must be exercised in the installation of plant of this class, and that in the interests of efficiency it does not do to take anything upon trust when dealing with it.

Feed water in many installations accounts for a good portion of the works' costs, and is frequently the source of waste. In most cases, if a boiler has to be repaired or cleaned, it is blown right down into the sump and all the water thus lost, but this is not at all necesary if the blowing-down arrangements are properly designed and used. There should be a main blow-down pipe, into which all the boiler branches lead, having a valve in it between the last boiler and the sump. When a boiler is to be emptied the main valve should first be shut, the valve in the blow-down pipe of an empty boiler and its safety valve opened, and the boiler then blown down. This will result in the saving of practically 50 per cent. of the water, as this amount will naturally flow into the empty boiler before the water levels become even. The other 50 per cent. must be lost, but the saving is considerable, especially when large boilers are used.

The losses that occur in steam-pipe work account for a large proportion of the total. They are due to four causes—leaky joints, long runs, bad covering and inefficient steam traps. Persistently leaky joints cannot be cured except by some structural alteration in the piping. Practical experience proves that, although some jointing materials are better than others, the best will not cure a defect arising from bad workmanship, and for this reason it is imperative that pipework should be of the best quality and erected in the most careful manner possible, with due provision for staying and expansion. The causes of leaky joints are badly faced flanges, pipework that being too short has had to be pulled together on the last joint, inefficient expansion and draining apparatus. If flanges are badly faced, or do not meet truly all around, the cure is obvious—they must be faced up properly; experiments with jointing materials are waste of time and money. If the work has been pulled together in a straight length where there is no allowance for expansion, there are two remedies open—either to provide an expansion bend or joint, which is costly, or, preferably to insert a carefully shaped and faced distance piece between the two open flanges. Should a certain length of pipe persistently give trouble with all or several of its joints, this points generally to expansion or water troubles, and should be carefully investigated; it may be that the staying is too tight and does not allow the contraction and expansion to be taken up on bends, as is generally the case. If this is so, an expansion piece must be inserted, preferably a U-shaped piece, not a joint, as the latter always leak. This will be found, in the long run, the cheapest remedy.

Should the trouble be located as due to water, it means that the draining arrangements are inefficient or not properly used, and the best way to set about a cure will probably be to install an extra drain pipe at some low part of the range, or to overhaul the steam traps. These latter are often very troublesome chiefly owing to inattention. They are too frequently stowed away in practically inaccessible places, and there left to chance their luck, year in and year out, with little or no inspection. If such is the case, they are bound to become in time either useless or wastful—that is to say, they will either not let anything through them or will go too much the other way and pass steam and water indiscriminately. Traps should be in sight, above the floor level, and under constant observation; if placed like this, leaking and waste or refusal to work is bound to be noticed at once.

Condensation losses through long runs of pipe can only be minimized by judicious manipulation of the section valves, allowing only just as much pipe to be alive as is commensurate with convenience and safety. This in some large stations has been reduced almost to a fine art, and there is no getting away from the fact that the amount of thought and organization necessary is amply repaid by the increase in efficiency. In a large station with a dozen or more boilers, and perhaps as many steam sets, the efficient working of the pipe range is by no means a simple matter, the economic possibilities, of course, depending greatly upon the style of arrangement. The only way to secure maximum economy is to work upon a system—that is to say, as far as practicable, certain engines should be run when certain boilers are in service, taking care that the steam way is the shortest possible between the two. In a small station, or with a simple straightforward arrangement of piping, there is not much in it, but with some of the old-fashioned elaborate ring or duplicate systems that are fortunately dying out, the possibilities are immense.

Much has been said about pipe and boiler coverings, particularly by manufacturers. It is therefore only necessary to reiterate that to allow even the smallest portion of steam-piping to go inefficiently covered or entirely bare, is simply throwing money away. Condensation tests on covered and uncovered pipe are frequently quoted, and the writer would commend their perusal to engineers who do not appreciate the enormous losses entailed by bad lagging.

In all well-managed stations the engines are indicated at frequent intervals—a very necessary precaution, from the neglect of inefficiency often arises. The comparative economy of engines, of course, depends chiefly upon their design and building, and cannot be improved unless drastic structural alterations are made, but it is necessary to guard against the minor losses that occur through wrongly set valves, leaky joints, glands, etc., and the frequent use of the indicator is the only way to check the first and most important of these. It is not sufficient to take cards and so get an indication of the general action of the steam in the cylinders—they should be worked out in order to ascertain whether the work is evenly distributed; if it is not, an uneven turning moment is the result, and unequal wearing of the brasses. This, when very bad, has often been the cause of persistent hot bearings on one side of the engine, and consequent expense and trouble in repairs, that by an intelligent use of the indicator might have been entirely obviated. The glands of inclosed engines when covered in naturally do not, as a rule, receive as much attention as those of the open type; they are, however, apt to be just as troublesome. The surest indication of their leaking is excess of water in the crank chamber, and if the amount of this is systematically observed, a certain check can be kept upon their condition.

In all stations during the heavy load it is necessary to keep a certain amount of plant in a condition to be put to work at the shortest notice. From the point of view of economy this is a very important point, indeed, and a great deal of experience is necessary to say when the expense of keeping spare plant turning over or warmed up is exactly counterbalanced by the increased safety. The primary considerations are, of course, the condition of all or any one of the running sets or boilers, as regards freedom from breakdown, the amount and nature of the load,

and whether rising or falling; upon these, again, is imposed what may be termed the component of local conditions, and the whole makes a very pretty problem for each individual station engineer.

To tackle the question from the commencement, boiler stand-bys, in anything but the very largest stations, are practically unnecessary—that is to say, if the boilers are well looked after; there may be a little risk in this, but the expense of getting up steam in a spare boiler every day, only to let it down again, is in most cases prohibitive. In a small station, therefore, there is but little choice in the matter—so many boilers will be required for the peak of the load, and so many must be steamed. Until the maximum is reached, and after it, there is plenty of stand-by, the only risk taken is at the peak, and as this is not as a rule on for long, it is worth running. In a large station, however, things may be rather different; the expense of steaming up a spare boiler or two is proportionately small, and the usual procedure, therefore, is to use more than enough boilers for the work, thus having something in hand in the event of breakdown. As it does not pay to force boilers, this method, besides being safe, is perhaps economical, and its use in small installations is only debarred by the proportionately large cost of raising steam and banking fires.

It is on a rising load that stand-by engines are chiefly required; when the load is falling, this precaution, is, in most cases, not so necessary. It all, however, depends upon conditions, such as the size of the sets, and whether they can be run up to speed quickly. If they are small, and of the high-speed inclosed type, warming up is generally sufficient to meet all the requirements of safety, as such engines can be got up to full speed from standing in a few seconds; but with heavy plant the case is different, and unless the spare set can be run up to speed and ready for taking load, say, in about 30 seconds, it is necessary to keep it turning over. This, of course, entails unprofitable use of steam—that is to say, unprofitable, inasmuch as it does not go towards the generation of current—but it is a highly necessary precaution, and on a rising load the loss is scarcely to be begrudged, seeing that the spare set will probably go into parallel very shortly. In the case of a fog load, questions of economy in this direction must, of course, be thrown to the winds; but in dealing with the ordinary evening load, with its predetermined value at certain times, a system based upon observations and energetically carried out, will do much to reduce what is sometimes the very considerable loss entailed by the keeping ready of stand-by plant.

THE LATEST PROGRESS IN WIRELESS TELEGRAPHY.

BY EMILE GUARINI.

Translated for "Electricity" by Jean A. Wetmore, M. S., E. E.

(*Continued from page 234.*)

The time seems to have arrived for us to point out a device, which appears to us as having the same advantages as the Fessenden device and which eliminates its disadvantages. It is known that when the transmitter is not grounded the transmission distances are much less than when it is grounded; it is then only necessary to have the transmitter operate constantly and to insert a key in the ground circuit, the receiver being then effected when the ground circuit is formed.

Speaking of receivers, M. Ferrie recalled the Marconi "magneticum detector" (Fig. 13). In this detector there

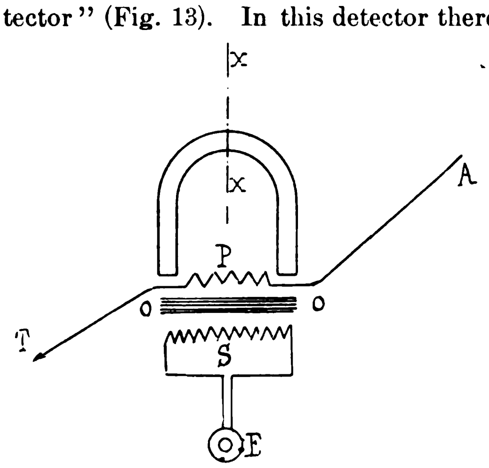

FIG. 13.

is a core, O, composed of iron wire, on which are mounted two superimposed circuits. One of them, P, is made up of a short length of copper wire, which is connected to the antenna and to earth. The second winding, S, which is much longer, is connected to a telephonic receiver, E. Fronting the sides of the core extremities are placed the poles of an iron horseshoe magnet, which turns about its axis, X, at a speed of about one revolution in two seconds. The magnetization of the core is consequently constantly varying.

The variations in magnetism resulting from the action of the oscillations passing through the circuit, P, set up induced currents, which effect the telephone, E; the signals received are thus read by sound. This detector has the advantage over a coherer, in that it does not require adjusting and is perfectly uniform in its operation, but it is not as yet demonstrated that its sensitivity is as great.

For those who are interested in the history we will mention that this device is, as a whole, a deviation from the device on which we were the first to experiment, and which was later used by Ruhmer from 1900 to 1901, in which there was an antenna connected to earth across the primary of an induction coil, of which the large wire of the secondary (the trans-

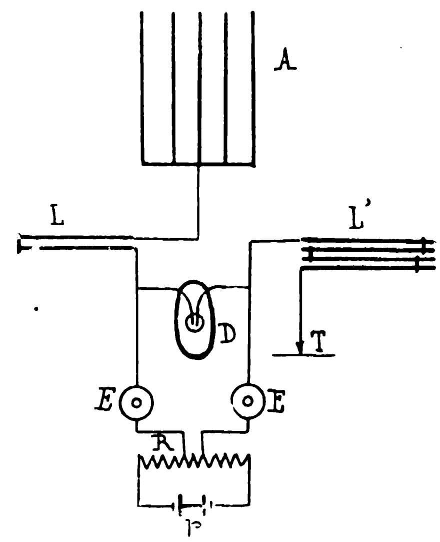

FIG. 14.

former transformed the Hertzian waves at low tension) contained a telephone, having its core magnetized by the Hertzian waves. Marconi added thereto the property discovered by Rutherford, and now the telephone is used as a receiver in those systems which produce long lengths of waves, especially those in which the two effects predominate.

The speaker further stated that Mr. Fessenden has been able to construct bolometers during almost two years (Fig. 14), which have a sensitiveness, we are told, favorably comparable with the best coherer, and having the same advantages over them as the Marconi detectors.

In Fig. 14 D is a glass bulb, A is the antenna, T the ground, LL^1 the harmonizing device, E the telephone receivers, R the resistance of the potentiometer. The antenna is tuned up by shifting the plates LL^1. M. Ferrie states that he has no information regarding the results obtained by this procedure, but this has undoubtedly escaped his memory, for the Fessenden device has been experimented with and has given satisfactory results.

M. Rochefort has recently proposed the device, referred to later on (Fig. 15), by using the ordinary coherer as a wave detector. The antenna is grounded through several coils of the bipolar resonator U. When the number of coils and their lengths are properly selected the

resonator will vibrate in unison with the antenna, and two maximums of equal tension and opposite polarities will be produced at the extremities, the coherer being connected to it, but for the purpose of doing away with the use of condensers, so as to prevent the battery from being short-circuited by the resonator, the coherer has three terminals, i.e., is made up of two coherers in series. The relay battery circuit is connected to the central portion of the coherer and thence to ground.

M. Ferrie then opened up the discussion, and stated that every one makes use of the electric spark for the purpose of obtaining high period electric waves, and as a result the oscillations cannot help but be deadened.

We have proven that electric waves of very low frequency suffice for wireless telegraph purposes. This is easily explained when we consider that the phenomenon of wireless telegraphy is particularly based on conduction through the

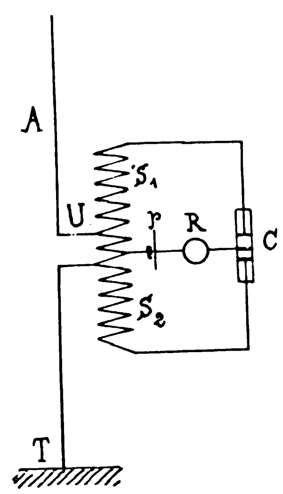

FIG. 15.

earth, or through the sea, and likewise through the atmosphere. Furthermore, it remains to be theoretically proven why Hertzian waves of high frequency should produce better effects than low frequency waves. An observation is to be noted in regard hereto. In the Hertzian waves the energy employed during a definite period is subdivided into a very large number of waves, whilst in a low frequency current the same energy is divided into a number of much smaller waves, consequently these waves are of a much greater energy and they can carry much further. From trials, unfortunately over a short distance, we have proven, by employing a telephone as a receiver, that our way of looking at the matter is correct.

All the proposed devices for transmission can, according to M. Ferrie, be classed under one of the three following types:

First—Directly excited apparatus (Fig. 16), in which the antenna and the earth take the place of a condenser for utilizing the discharge.

Second—Apparatus excited by induction, such as the Braun (Fig. 17). The

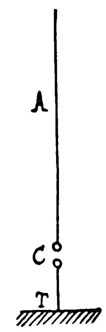

FIG. 16.

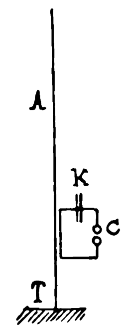

FIG. 17.

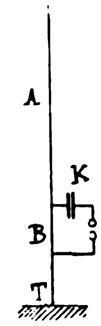

FIG. 18.

exciting oscillations are produced in a closed circuit, KC, and act immediately upon the antenna, A, the capacity, K, being so chosen as to harmonize with the period of the antenna itself and with that of the excitation.

Third—Apparatus using excitation by derivation, such as the Slaby (Fig. 18). The antenna is simply placed in shunt upon the exciting circuit, it still being necessary to harmonize the exciting period with that of the antenna.

Concerning the utilization of the energy expended for the charge the first type is the best, as it does not admit of any losses through induction or through derivation. We will also add that it is the best because the energy is spent almost as a whole by the first oscillation.

The third type appears the least good, as it allows of vexatious losses of energy arising from the production of two species of oscillations, although only one of them is taken up by the receiver. The first kind of oscillations are those pertaining to the antenna, ABT, and the others are those of the circuit, AKCT.

On the other hand, the first type produces oscillations which are much more deadened, for really the loss by radiation in this case absorbs all the energy, whilst in the other system there is only a partial loss of the total energy produced.

In the first type each discharge in reality gives only one oscillation, which is very energetic, acting upon the receiving circuit like a percussion; and this oscillation, nevertheless, appears to furnish a well determined and constant period, in spite of observations to the contrary, when a single antenna is used, and its effect upon the receiving circuits is at a maximum when both have exactly the same period.

It appears appropriate at this point to recall to mind that for a long time past Mr. Marconi has proven that even by direct transmission it is possible, even to a limited extent it is true, to prevent disturbances between stations having antenna of quite varying lengths.

(To be continued.)

ELECTRICAL STATION PRACTICE.

ARTICLE XXXV.

BY W. H. RADCLIFFE.

Although man possesses no specialized sense for the detection of electrical forces, it has been proved that each of the five special senses he does possess, namely—seeing, hearing, smelling, tasting and feeling, can be effected by a current of electricity. Ritter, for example discovered that the passage of a weak current through the eyeball caused the optic nerve to produce the sensation of a bright flash of light. So minute is the current necessary to produce this effect, that similar results may be obtained from a battery cell formed by placing a strip of metal under the tongue and bringing it in contact with another strip of metal touched to the moist tissue of the eye. Volta found that musical sounds were produced in the head when a current of electricity was passed through the ears; Humboldt discovered that the passing of a current from the nostril to the soft palate caused a perceptible odor, and Sulzer first detected a peculiar taste when two dissimilar metals placed upon the tongue were brought in contact with each other. It requires neither a Ritter, a Volta, a Humboldt, or a Sulzer, however, to prove to the average station attendant that the sense of feeling is readily affected by a current of electricity. The sensation thus experienced under direct current pressures up to 100 volts is of a prickling nature, seemingly centered at the joints; at 100 volts the sensation becomes rather painful and is accompanied with an involuntary contraction of the muscles. At 200 volts the sensation is intensified, but the degree of painfulness varies with different persons.

Persons of a weakly or nervous constitution, or those who suffer from damp hands, are much more susceptible to electric shocks than are strong healthy persons having comparatively dry skin. A man whose constitution is of the former type cannot generally endure more than 60 volts direct current from hand to hand without painful sensations, while a person of the latter type can usually stand 200 volts or more. The shock received from an alternating current is more severe than one of equal voltage received from a

direct current, and the results are also more fatal. A pressure of 50 volts direct current, for instance, will not usually cause unpleasant sensations, but under the same conditions a pressure of 25 volts alternating current will be found very disagreeable. It is well, therefore, to exercise proportional care when working with these two different forms of electricity.

Under ordinary conditions the resistance of the human body is about 2,500 ohms, the greater portion of this resistance is caused by the skin, which if perfectly dry has a resistance of 100,000 ohms. It is obvious, therefore, that the condition of the skin is the determining factor regarding the seriousness of a given pressure below 200 volts. As accidental contacts with live conductors in a station generally occur about the hands and arms where the skin is dry and hard, no serious results need be anticipated from pressures of 200 volts or less. When dealing with ordinary working pressures above 200 volts, however, it is necessary to exercise care in proportion to the increase of the working voltage above this amount, and this is especially true where alternating currents are employed.

It may be well to emphasize the fact that it is not the electromotive force or voltage that produces death. The voltage is, of course, directly responsible for the current, but it is the current alone that is the direct cause of fatalities. It has been ascertained at official electrocutions that it is necessary to pass less than one ampere (about .8 ampere) of current through the vital portion of a human body in order to cause death. It has already been stated that proportional care should be observed when dealing with ordinary working pressure above 200 volts. When alternating currents of higher than the ordinary working pressures are considered, such as 100,000 volts or more, there is really less danger to life than with alternating currents of normal pressures. This is due to the higher frequencies which accompany the higher voltages, and which tend to greatly increase the internal resistance of the body; subjected thereto the resulting current is thereby forced to the outside and passes harmlessly over the surface of the skin.

Electrical shocks are seldom beneficial to the system unless administered modererately and they be under complete control. Accidental shocks are therefore to be avoided under all circumstances, and it is possible to do so if all connections be made before the current is switched on the circuits. Use should therefore be made of the main switch in each circuit requiring repairs or alterations, opening the same whenever work of this nature is to be done and closing it upon completion of the task. The conductors will therefore be entirely disconnected from the supply circuit and consequently dead, while undergoing repairs or alterations, and accidental shocks will be entirely avoided. In cases where the interruption of service caused by the opening of the main switch would be of a serious nature, it is necessary to work upon live wires. While this task is not an enviable one at best, the danger associated therewith may be reduced to a minimum by following a simple rule. This rule is, when working on one conductor, avoid coming in personal contact with any portion of the circuit at a different potential from this conductor. Rubber gloves, rubber shoes, or both, may be used for this purpose; if, however, these articles be not provided, it is advisable to stand on dry wood and work with one hand as much as possible. Working with one hand reduces the chances of the other hand breaking the rule previously given, in which case the current would pass directly through the body from side to side. As there is always an inclination from force of habit to use both hands simultaneously, it is best to keep the unemployed hand in the pocket in order to make sure not to use it.

When working on high potential circuits carrying alternating current, it is necessary to be ever on guard, not only to avoid coming in personal contact with live conductors but also to protect one's self from leakage of the current, which latter feature is often excessive in installations of this nature. The best of insulation often fails to prevent leakage from high voltage alternating current conductors, and they should not be touched unless one is standing on a thoroughly insulated support and protected with all the safety appliances known to the art. In mentioning safety appliances, reference is here made to rubber gloves, rubber shoes, and tools provided with rubber-insulated handles. If the precautions previously given are carefully followed, the dangers associated with electricity will be reduced to a minimum. It has, however, been said that familiarity breeds contempt, and an inspection of statistics shows this to be the case regarding electrical fatalities of an accidental nature. Practically all persons who have been killed in this manner have been expert stationmen and linemen who, through long acquaintance with dangerous currents, have become careless in observing the simple precautions already presented in this article.

As to the sensations experienced by one receiving a fatal electrical shock, it may be stated there does not appear to be an instantaneous loss of consciousness, that is, consciousness is not lost synchronously with the beginning of the shock, and death does not instantly follow, although it may be said to supervene with great rapidity. The period of consciousness, although extremely brief, seems to be sufficient duration for the victim to perceive that an electric current is passing through him, and this sensation, though indescribably unpleasant, seems to be comparatively painless. The effect of a fatal current on a human body is as follows: It primarily effects the nervous system, causing spasms, after which it destroys the tissues by burning or by electrolytic action, coagulating the blood. The conditions are such that the same restoratives used in reviving drowned persons should be employed in resuscitating victims of electrical shocks. The object in all cases is to create a circulation of the blood, and this requires prompt and continued efforts if successful results are to be obtained. Accidental shocks very rarely terminate fatally unless the victim is left unaided for too long a time, or attempts at reviving him are stopped too soon.

The method of procedure for resuscitating victims of electrical shocks from apparent death is as follows: The first step should be the removal of the body from contact with the current-carrying conductors. In doing this it is necessary to protect one's self from a similar fate by using some insulator, such as a dry stick of wood, to separate the wire from the body or the body from the wire. When rubber gloves are worn the separation can much more readily be accomplished for then there is no danger in touching the body of the victim. If rubber gloves are not conveniently near, and it be found necessary to employ the hands, a dry piece of cloth or clothing may then be used to protect them in place of rubber gloves. In case the body is in contact with the earth, the separation can usually be affected by grasping some part of the clothing on the victim and by means of this pulling him to a place of safety.

The rescue having been accomplished by employing one of the methods previously suggested, the body is placed upon the ground, back down. In order that the conditions may be favorable for reviving the victim, in other words, establishing respiration or breathing, it is necessary to have the collar and clothing about his neck loosened and his head well thrown back. By rolling up a coat and placing it under the shoulders a proper

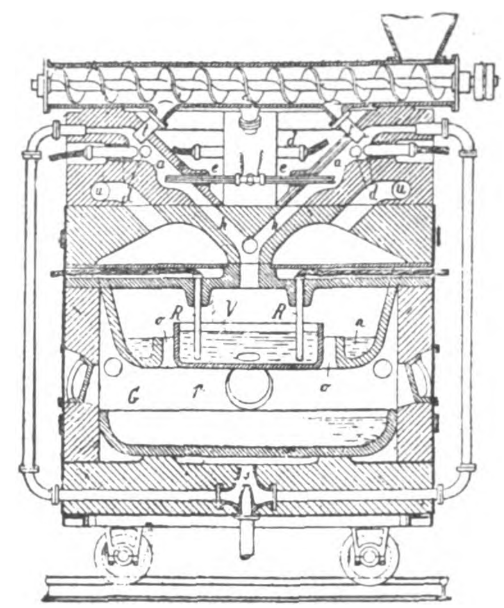
inclination of the head can be readily obtained. This having been done strenuous efforts must be made to induce breathing. To accomplish this in the most effective manner requires the services of two persons, one kneeling at the head of the victim for working his arms, and the other stationed near the center of his body for manipulating his tongue. The party kneeling at the head should grasp the arms of the victim and draw them to full length over the head, keeping them quite closely together. This movement tends to expand the chest and permits air to enter the lungs. The arms should be held extended in this manner for about two seconds and then pushed down to the sides and front of the chest, compressing them thereon. This latter movement tends to force the air out from the lungs. After the arms have been held upon the chest for about two seconds, they should again be extended over the head to full length as already explained. This complete cycle should be repeated at least sixteen times per minute for half an hour, or until natural respiration is established.

Simultaneous with the movements just explained, the party manipulating the tongue of the victim should quickly draw it out of his mouth to the limit, when his arms are being extended above the head, and permit it to return to its normal position when the arms are compressed upon the chest. The object in this movement of the tongue is twofold; when withdrawn, the throat is cleared so as to afford a free passage for the air to enter the lungs, and at the same time the friction between the lower part of the tongue and the lower teeth tends to induce an involuntary effort at breathing. As in the case of the arm movement, the motion of the tongue should be repeated at least sixteen times per minute for half an hour, or until natural respiration is established. In order to obtain a firm grasp upon the tongue, it will be found necessary to place in the hand a piece of cloth or a handkerchief so as to prevent it from slipping. If there is difficulty in reaching the tongue, owing to the jaws being clenched, there should be no hesitancy it forcing it open either with the handle of a knife, a stick of wood or any article that will answer the purpose.

In addition to the preceding directions, the application of ice to the spine, the dashing of cold water in the face, and the alternate application of cold and heat over the heart has a tendency to start the breathing apparatus. Oxygen gas, if obtainable from a nearby drug store, may also be advantageously employed during the previously described movement of the arms. The best method of applying it consists in forming a piece of stiff paper into a cone and placing the larger opening over the mouth and nose of the victim, while the smaller opening is attached to the tube leading from the oxygen tank. If the oxygen gas can be thus induced into the lungs, it will act with good effect as a stimulant upon the heart. Under no circumstances, however, should liquid stimulants be poured down the throat, as such a practice in a case of this kind is not only of no benefit, but is on the other hand distinctly injudicious.

AN ELECTRIC GLASS FURNACE.

Electric furnaces are giving good results at the large glass factories at Matrei, in Tyrol, and at Plettenburg, in Westphalia. The accompanying illustration



shows the tubes, *t t*, through which the raw material enters the top of the furnace, whence it is conducted in front of the arcs, *a a*. The heat of the arc fuses the material, which then drops into the receptacle, *V*, where its temperature is considerably raised by the resistances, *R*. From *V* the molten glass, of its own accord, descends into the crucible, *G*, which is heated by an upward flame, *P*. The latter is formed by the gas which is developed during the fusion of the material. This gas is collected and conducted to *P* by means of the lateral tubes, *r*. Although this furnace has given satisfactory results a new type has been constructed in which the raw material, before having been exposed to the heat of the arc, is made into a paste with water. It is then pressed and dried, and finally it passes, in the shape of a ribbon, through the arcs between a number of electrodes, out of which it emerges completely fused. The heating is chiefly done by radiation, and care is taken to prevent impurities from the carbon entering the molten glass.—*Electrical Engineer, London.*

ELECTROLYSIS.

The following interesting communication was sent by Mr. H. W. Spang to the Brooklyn *Eagle:*

In my letter in your issue of April 19, in reference to electrolysis in Brooklyn, I asserted that in every case investigated by me the path of the traction current between an electric railway and water, or vice versa, was clearly defined.

It is owing to the fact that the true action of the current of the overhead trolley railway has never been thoroughly investigated by electric railway engineers that the introduction of the proper remedy for electrolysis has been delayed.

The average electric railway engineer apparently cannot comprehend why a traction current should leave a circuit with a good metallic return, such as a pair of track rails, provided with the most improved fish plates and copper bonds, and even with a supplemental copper or other metal return conductor. It, nevertheless, does escape, as is testified to by twenty experts in the Dayton, O., electrolysis case, and as experienced in every city and town where the grounding conditions are favorable.

Electric engineers have blundered in determining the requirements for electricity in a working circuit by the comparative conductivity of copper and water as tested in the laboratory. Most electricians imagine that water is a poor conductor of electricity, being governed by the statement in the electrical text-books that pure water is a non-conductor, which refers to a small quantity of distilled water in a tumbler, subjected to the ordinary galvanometer or conductivity test in a laboratory.

I have found that when the water (fresh or salt) of a swamp, creek, river or other waterway is properly utilized it is an excellent conductor of low or high potential electricity.

There is an erroneous impression that the current from the positive pole of a generator flowing to earth or water at one or more points returns through the earth or water to the negative pole. It does nothing of the kind. It simply causes a corresponding current flow from a suitable area of earth or water to the negative pole.

The radiating nature of electricity is revealed in wireless telegraphy. It does not return to its source.

Electrical research has principally been

confined to the laboratory, which has resulted in the rapid development of electric generators, motors and other electrical apparatus. In fact, the advance in electric generation has been far more rapid than the determination of the means for afely employing powerful electric energy, which can only be ascertained through a thorough investigation of the action of electricity in a working circuit and not in a laboratory.

It is about time that the laboratory be altogether ignored in the determination of lightning protection requirements. The ordinary lightning rods and the usual devices employed with electrical circuits cannot afford protection from lightning discharges or intense induced electric charges.

Absolute lightning protection can only be effected by a proper system, based upon true scientific principles. The number of lightning fires in this country have increased from 625, with a loss of $1,618,-539 in 1890, to 3,440, with a loss of $5,272,835 in 1900. During the eleven years, 1890-1900, 588 churches, 10,742 barns and 5,907 other buildings, mostly in the suburban sections, were ignited by lightning, with a loss of $30,611,284. There were also many cases of shattered churches and buildings without being ignited.

In addition to the eleven year period of sun-spot maxima, astronomers claim that at intervals of about 33 to 35 years there is also extraordinary solar activity, attended with great eruptions or protuberances on the sun, extending in some cases to a height of about 300,000 miles, and accompanied with numerous auroras, magnetic storms and the most terrific thunder storms upon the earth.

Such excessive solar activity and phenomena last occurred during the three years, 1870-72, and during thunder storms on August 14, 15 and 16, 1872, the induced electrification of the earth was so intense in some sections that railway trains while running were surrounded by a vivid light and the fusion of lengths of telegraph wires and the destruction of poles and telegraph apparatus and igniting of telegraph offices, especially in suburban sections, was general. During the said three days over 200 dwellings and a large number of barns in New York State and the New England States alone were ignited or otherwise damaged.

There was no telephone, electric light or trolley railway wires during that year, and it is somewhat with misgivings that we can look forward to the next three summers, especially in view of the fact that under the present electric engineering practice lightning discharges are encouraged to take place in line with overhead telephone, electric light and trolley railway wires and enter buildings and cars and destroy or damage them, regardless of the arresters, choke coils and safety fuses employed with such circuits.

ELECTRICAL EQUIPMENT OF A CANAL.*

BY F. H. LEONARD, JR.

(*Concluded from page 235.*)

LOCK HOUSES.

At the upper end of each lock on the south bank there is located a small switchboard cabin, 7 feet x 9 feet; on the little island between the two locks is located another switchboard cabin and at the upper end of the lock on the north side of the second lock is another cabin. In the first of those above mentioned are placed three transformers and connecting to the 11,000 volt mains, which step voltage from the line pressure to 550 volts, and it is at this pressure that the motors operate. A high tension fuse board is provided to take care of the primary connections to the transformers. The long inclosed fuse has friction contacts at either end and by pulling these fuses out of the end clips by means of a wooden stick with a hook at the end, the circuit can be opened in case of temporary trouble, or for any purpose whenever it becomes necessary to disconnect the transformers. The secondary of the transformers passes through the switch on the switchboards which distribute the secondary current to the motors, two of which are located on each side of the lock. Armored cable with paper insulation is used to conduct the current from the switch cabin to the motors located on the same side of the lock.

The connection for motors on the opposite side is carried through armored cable which leads down through the floor of the switch cabin and passes through a hole drilled in the stone coping of the lock to the upper stop log check; there being two checks cut in the masonry, this leaves one which could be utililized for stop logs in case it ever became necessary to keep the water out of the lock during repairs. The cable turns over a radius of 16 inches at the top and passes down the check, being protected by a piece of oak plank which is grooved in the center to take the cable, the plank being fastened by drift bolts to the stone work and protected at the edges with iron strips. As the plank does not come above the edges of the check in the stone work there is practically no danger of the cables ever being injured by a boat in entering or leaving the locks.

Where the cable crosses on the lock bottom a timber is held on top grooved on the bottom side to receive the cable, and as the top of this timber is well below the breast wall at the entrance of the lock there is no danger of the cable ever being disturbed.

Rising on the opposite side of the lock in the stop lock check, the cable again passes through a hole drilled in the stone coping until it comes out of the earth back of the masonry under the next switch cabin; from this switch cabin the cable is carried into the third switch cabin on the north side of the old locks.

You will bear in mind that the new locks were built on the south side of the old locks and are about 70 feet longer, the old locks being 55 feet wide and 200 feet long inside the gates and the new locks 45 feet wide and 270 feet long inside the gates and 14 feet over sills.

On the switchboards in each of the cabins are placed the motor starting switches connected to auto starters which control the motors on one side of each lock. From the switch cabin on the south side are operated two motors, the first motor being connected by armored cable reaching from the switch cabin underground to the first motor. The second motor is reached by conductors running from the switch cabin overhead to a pole very near the motor at the lower end of the lock—armored cable connecting from the pole underground as far as the masonry and checked into the masonry where it passes over to the motor.

The switch cabin on the little island between the two locks controls the two motors on the north side of the new locks and two motors on the south side of the old locks. The third switch cabin controls the motors on the north side of the old locks, as well as the motor operating the weir gate mechanism.

The arrangement is identical in all the locks with the exception of No. 15 and old lock 16, which are not provided with weir gates. The equipment for operating the lock gates and weirs was adapted for use in connection with the winches and weir gate mechanism already installed without disturbing their capability for hand operation should occasion require. When these devices were operated by hand, the lockmen laboriously turned a crank on the winches at the two opposite sides of the lock gates, utilizing one winch for opening and the other for closing the

*Abstract of paper read before the Electrical Section of the Canadian Society of Civil Engineers, Montreal.

gates. Four winches were located at each end of the lock, two on each side, one of which handled the chain to close the opposite gate, the other to open the gate on the side at which these winches were located. Across the top of each gate is a bridge on which is mounted the worms and rods for opening the two valves in each of the gates when required to fill or empty the lock.

The electrical equipment utilized practically all of this machinery as it stood with only the necessary changes to make the mechanical connections with the electrical drive.

In order to keep the speed down to approximately what was obtained by hand operation, a very material reduction in motor speeds was necessary. To obtain this and cover the other points, special apparatus was devised and patented by Mr. Alex. Pringle and myself.

The motors selected were all of a 5 hp. for both the lock gates and weir mechanism. Some question as to whether a 3 or 5 hp. motor should be adopted arose, but the matter was decided in favor of the 5 hp. motor on account of of its lower speed, and while the capacity of this motor is never exceeded except for a few seconds, the balance of the time running considerably under load, yet the whole arrangement is simple and while somewhat stronger than absolutely required, the interchangeability and greater durability we thought justified the slight additional expense.

To operate the two winding winches which control the chains for opening and closing the gates, one motor is located near the hollow coin at the heel of the lock gate—which is coupled by means of a short length of shafting and friction clutch coupling to the winch near this point and by means of another friction clutch and length of shaft sufficient to reach the other winch, supported at intermediate points by pedestals carrying journal boxes mounted on cut stone blocks jointed to the coping, making a practically continuous stone foundation for the mechanism.

As there is a reduction of about 42 to 1, which gives a speed of about 26 revolutions for the operating shaft, we concluded to use the worm gear rather than a more complicated triple reduction by means of spur gears. A sub-base extends under the motor and also carries the casing for the worm and worm gear. The worm runs in oil, the thrust being taken up by alternate steel and bronze collars and thrust disks, adjustable at one end by means of set screws and check nut to compensate for wear.

The motor, which runs at 1,200 r.p.m., is coupled directly to the worm shaft, the worm being cut out of solid steel and meshing into a hobbed bronze wheel turning on a shaft mounted on babbitted bearings; the projection at one end of this shaft having mounted upon it the friction coupling controlling the working shafts. The opposite end being coupled to a short length of shaft which carries a chain wheel similar to a sheave in a chain hoist and from this point by means of a welded link chain made endless, is turned at an angle to the main working shaft, the supplementary shaft for operating the valves in the lock gates. This shaft is supported on bearings secured to the coping of the lock and placed about ½ inch above its surface and continued under the bridge on the lock gate, a universal coupling being utilized at a point near the gate pivot so that the travel of this joint is minimized.

The arc of the circle through which this coupling passes is provided for by a swivel box carrying the end of the driven shaft, and the travel in and out is allowed for by having the chain sheave run free on the shaft except when engaged by a jaw clutch keyed to the shaft so as to allow the shaft to run in and out as it passes through this arc and engage or disengage the clutch at the proper time for controlling the valve mechanism. The clutch being disengaged allowed the driving sheath to run loose on a shaft, the shaft itself remaining idle during the time the gate is open and is only put into operation when the gate is swung to the closed position.

The valves are operated by bevel gear reversing mechanism which allows the operator to either close or open the valves in the gates by throwing the shipping lever which engages a jaw clutch with one of the bevels required to operate the valve stem in the desired direction. The travel of this stem, however, is limited by an automatic stop consisting of a loop and bell crank operated by a pin in the cross head traveling with the valve stem so that at the lower or upper limit of travel, the pin trips the bell crank connecting with the shipping lever so as to throw the clutch out of engagement with the bevel gear which produces the motion.

This mechanism permits of much more rapid lockage than could be carried out by hand and reduces the necessary force of lockmen to one-half the crew formerly required.

LOCKAGES.

While the usual lockage is perhaps a familiar sight, many possibly do not understand it, and a short description will not be out of place.

We will assume that a barge is proceeding up the canal, following another which has previously passed in the same direction. The lock would, of course, be full of water up to the level of the section above. As the barge approaches the lock, the lockmaster starts the motors at the lower end by means of the starting switch on the switchboard in the lock house and two of the lockmen proceed to the lower gate and open the valves, which allow the lock to empty into the lower reach; the mechanism is started on all four valves one after the other. One of the lockmen crosses to the south side and the other to the north side. The mechanism operating the valve stem continues to operate until the valves are wide open and the pin trips the operating mechanism, leaving the valves in this condition until the water within the lock has reached approximately the level of the lower reach. The lockmen on each side of the canal then throw in the friction clutch, which connects by means of a short shaft to the pinion meshing into the large spur wheel on the winch. This winds up the slack on the chain which runs through the chain well over a roller and out to a hook about 4 feet above the sill at the outer end of the lock gate.

As soon as the slack is wound up, the chain commences to move the gate, opening it till it leaves the passage free for the entrance of the barge into the lock. As soon as the boat is moved into position and made fast, the gate is closed by throwing in the opposite clutch which operates the winch at the opposite end of the shaft and closes the gate—the clutch on the first winch being released, of course, allows the chain to pay out as quickly as required to allow the gate to close.

As soon as the gates are closed, the clutch operating the shaft which drives the valve mechanism has moved into engagement and starts the valve driving mechanism, the lockmen throw the lever, starting the two valves in each of the lock gates to close and immediately walk over to the other end of the lock; before they reach it, however, these valves have closed and the tripping mechanism has thrown the clutch out of gear. The valves in the gates in the upper end of the lock are then opened in a similar manner to that described in the emptying of the lock and the water from the upper level flows in and fills the lock to the level of the upper reach. The upper gates are then opened in a similar manner to that described in connection with the opening of

the lower gates, allowing the barge to proceed on its journey.

WEIRS.

To keep the various levels of the canal normal, on account of excessive flow of water from above or any heavy draught of power used on a level or by lockages, the flow of water has to be compensated for by adjusting the weir gates. These gates are operated by worm and segment or in some cases by raising or lowering the valves in a manner similar to that on the lock gates, the operating of which is carried out in much the same way as described in connection with the gates.

As there are a number of weir gates or valves which must be capable of independent operation, provision is made by means of a double jaw clutch engaging with either one or the other of two bevel gears on a horizontal shaft which meshes into a third beveled gear on a shaft of the worm for operating the segment which drives the valve stems. The operator only has to throw the clutch into engagement so as to move the valve in the desired direction, and as soon as the gate has opened or closed sufficiently for the purpose of regulation the lever is thrown out of engagement with the gear.

BRIDGES.

The equipment for the bridges is operated by a motor driving the mechanism through worm gears, the same power unit being utilized as for the operation of the lock gates and weirs, an extension of the interchangeable idea. Aside from the first speed reduction, however, the gearing is quite different, though in the cases of both the Mille Roches and the Stormont bridges the arrangement is worked out on similar lines.

The bridge at Mille Roches is 179 feet x 12 feet and has the motor swung under the bridge just outside the turn table, being couterbalanced by weights at the opposite end of the bridge. A friction clutch communicates the power from the motor-driven worm shaft to one or the other of a pair of bevels, turning the bridge in whichever direction the operator desires. The clutches are operated by two removable levers coming up through the bridge floor so that the bridge tender has already control of both.

To swing the bridge, the operator first starts the motor, then throws the lever which withdraws the bolts, unlocking the bridge; one of the clutch levers is then operated so as to engage the bevel gear required to turn the bridge in the desired direction for opening. The friction slips for a while until it gets the bridge under motion, then it swings rapidly until it is nearly open, when the operator uses the other friction clutch (which tends to turn the bridge in the opposite direction), as a brake to retard the speed, and gradually bringing the bridge to rest in the open position. The reverse motion is used for closing and is operated in very much the same way.

National Electric Light Association Convention.

In addition to the New England Passenger Association and the Trunk Line Association, the Central Passenger Association and the Southeastern Passenger Association have made a rate of a fare and a third for the round trip from all points throughout their territory, for delegates and friends attending the 27th convention of the National Electric Light Association, to be held May 24-27, at Boston. Mr. Frank L. Perry will be in charge of transportation matters for Chicago and vicinity, and will arrange a special train to bring delegates to the convention.

Crocker-Wheeler Company Opens a Branch Office in New Orleans.

The Crocker-Wheeler Company, manufacturers of electric generators and motors, will on May 10 open a branch office in the Hibernia Bank Building in New Orleans. Mr. W. P. Field, of the St. Louis office of the company, will be the representative in charge. Although there are fifteen Crocker-Wheeler branches from Boston to San Francisco, including St. Louis and Atlanta, the establishment of this new office has become necessary in order to accommodate the steadily increasing market for electric machinery in the South and Southwest.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED APRIL 26, 1904.

Electric Railways and Appliances.

758,230. Train-Control System. Harold E. White, Schenectady, N. Y., assignor to the General Electric Company. Filed Nov. 20, 1902.

758,355. Trolley-Wheel. James S. Fletcher and Donald H. Waters, Chicago, Ill. Filed Sept. 3, 1903.

758,445. Trolley-Head. Peter D. Hean and John J. Egan, Media, Pa. Filed Dec. 26, 1903.

758,528. Current-Collector. John E. Greenwood, Utica, N. Y. Filed May 16, 1903.

758,592. Safety-Trolley. William M. Gruner and William C. Fink, Springdale, Pa., assignors of one-fourth to Henry G. G. Fink, same place. Filed Nov. 5, 1903.

758,594. Electric Railway-Signal. William S. Jackson Hoboken, N. J., assignor of one-half to David Young, same place. Filed June 30, 1902.

Electrical Machinery and Apparatus

758,057. Ground Connection for Electric Conductors. Frederick P. Fuller, New York, and John J. Walsh, Yonkers, N. Y. Filed Oct. 16, 1902.

758,084. Electric Time-Switch. Henry C. Little, Boston, Mass. Filed Aug. 26, 1903.

758,094. Electric Steam and Vapor Generator. Thos. W. Neely, Marshall, Ill. Filed April 23, 1901.

758,106. Transmission of Electrical Impulses. John S. Richmond, New York City. Filed April 27, 1901.

758,140. Magnetic Brake. John D. Ihlder, Yonkers, N. Y., assignor to the Otis Elevator Company, East Orange, N. J. Filed Sept. 2, 1903.

758,157. Means for Preventing Arcing Between Commutator Brushes. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company. Filed May 29, 1903.

758,164. Rheostat. William C. Yates, Schenectady, N. Y., assignor to the General Electric Company. Filed Aug. 16, 1901.

758,172. Blow-out Fuse. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 2, 1902.

758,173. Emergency-Brake. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Oct. 14, 1903.

758,174. Air-Brake Controlling-Valve. Fred B. Corey, Schenectady, N. Y., assignor to the General Electric Company. Filed Nov. 20, 1903.

758,194. Sanding System. William Schaake, Schenectady, N. Y., assignor to the General Electric Company. Filed Sept. 28, 1903.

758,225. Electric Motor. Alexis Vanderbeck, Roseland, Kan. Filed Oct. 10, 1903.

758,306. Electric Switch. Alan R. Fergusson, New York City, assignor to the Electro-Mechanical Specialty Company, same place. Filed Dec. 16, 1902.

758,324. Support for Electric Conductors. Fred C. Locke, Boston, Mass. Filed Jan. 24, 1903.

758,342. Switch Mechanism for Electric Signs. Frank S. Wahl, Buffalo, N. Y., assignor of one-half to Alfred W. Horn, same place. Filed July 14, 1902.

758,378. Alternating-Current Motor. Ralph McNeill, New York City, assignor to Arthur O. Granger, Philadelphia, Pa. Filed Dec. 4, 1902.

758,478. Electric Switch. Joseph H. Rusby Nutley, N. J. Filed June 25, 1903.

Electric Lights and Appliances

758,328. Device for Securing Incandescent-Lamp Filaments to Leading-in Wires. Albert W. W. Miller, South Orange, N. J., and George. P. McDonnell, St. Louis, Mo., assignors to the American Electric Company, East Orange, N. J. Filed July 3, 1903.

758,589. Light-Controlling System. Harry Faltermayer, Philadelphia, Pa., assignor of one-half to William J. Caskey, same place. Filed Oct. 2, 1903.

Telephones and Telephone Apparatus

758,116. Supervisory Signal Apparatus for Telephone Switchboards. Edwin H. Smythe, Freeport, Ill., assignor to the Western Electric Company. Filed Sept. 14, 1903.

758,200. Telephone-Climber's Seat. James E. Bennett, Momence, Ill. Filed Dec. 20, 1902.

758,304. Office-Desk Telephone. Alan R. Fergusson, New York City, assignor to the Electro-Mechanical Specialty Company, same place. Filed Nov. 16, 1901.

758,363. Telephone-Receiver. Miller R. Hutchison, Norwood, N. J., assignor, by mesne assignments, to the Hutchison Acoustic Company. Filed Nov. 25, 1902.

758,415. Telephone Instrument. Albert C. Christopher, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Feb. 3, 1904.

758,468. Alternating-Current Signal-Receiving Apparatus. Greenleaf W. Pickard, Amesbury, Mass., assignor to the American Telephone & Telegraph Company. Filed Feb. 29, 1904.

Miscellaneous.

758,202. Telegraph Receiver. Luigi Cerebotani, Munich, Germany, assignor of one-half to Albert Silbermann, Berlin. Filed May 2, 1900.

758,232. Telegraph-Transmitter. Charles Adams-Randall, New York City. Filed Aug. 25, 1902.

758,236. Electromagnet. Harold W. Chamberlain, Brunswick, Me. Filed Aug. 27, 1903.

758,250. Printing Telegraph. Clarence L. Healy, Newark, N. J. Filed June 16, 1903.

758,293. Electromagnetic Gearing. Edward M. Bentley, Lawrence, N. Y. Filed Dec. 2, 1903.

758,303. Electric Heater. Ernst Eckmann, Berlin, Germany, assignor to Martin Petersen, Friedrichsgabekoog, Schleswig-Holstein. Filed Aug. 15, 1902.

758,305. Electric Fan. Alan R. Fergusson, New York City. Filed Dec. 16, 1902.

758,517. Art of Wireless Telegraphy. Lee de Forest, New York City. Filed Sept. 21, 1903.

758,527. Signaling and Operating System. Hedley C. W. Graham, Rochester, N. Y. Filed July 9, 1903.

758,598. Transmission of Electrical Impulses. John S. Richmond, New York City. Original application filed April 27, 1901. Divided and this application filed Sept. 16, 1903.

Reissue.

12,214. Process of Obtaining Tin by Electrolysis. Ernest Quintaine, Argenteuil, France. Filed April 20, 1903. Original No. 699,012, dated April 29, 1902.

THE TELEPHONE WORLD.

Telephone Company in Washington Fixes Own Rates.

A provision in the District of Columbia appropriation bill, fixing the rates for telephone service in Washington, repeals the former act as far as concerns business houses, practically allowing the local company to name its own terms. It does, however, limit to $60 a year the amount to be paid by the Government for an individual metallic circuit line, and to $40, the amount for each telephone when two or more are on the same circuit and the same premises, and fixes like limitations on services for residences.

The previous law on the subject, enacted in 1898, made graded limitations for different services considerably lower than the new rates, but provided no penalty for violations. The local company disregarded the law and nearly 100 injunctions were sued out by subscribers to prevent the removal of telephones after the prescribed rates had been tendered. The cases were bitterly fought, being twice taken to the Supreme Court, which finally decided that the limitations did not apply to metallic circuits.

As the great majority of the business lines were of that character it was a victory for the company, and the subscribers who stood on the law were compelled to compromise their claims. Now Congress repeals that law entirely, raises the limit of cost for telephones in residences to $60 a year and permits the company to fix its own rates for business houses.

To Furnish Supplies for Independent Companies.

The Northern Electric Company has filed articles of association in the office of the Secretary of State at Burlington, Vt., and on May 2 opened headquarters in that city. The company is composed of Burlington and Boston capitalists, and will do a general electrical contract business, paying special attention to furnishing supplies to Independent telephone companies.

The Atlantic City, N. J., line, of the Keystone Telephone Company is expected to be open the middle of this month, making connections with the Atlantic Coast Telephone Company, a subsidiary of the Interstate Telephone Company, which has 1,600 subscribers in Atlantic City, which is about the same number as the Bell Telephone.

The Highland Telephone Company of Elmwood, Wis., formed to establish a telephone system in Pierce and Dunn Counties, is capitalized at $1,000, divided into 50 shares of $20 each. The incorporators are H. A. Miles, W. H. Young, Hugh Bell, Ira J. Smith and William Fensemaier.

A mutual telephone line is being built from Ogden, a station a few miles west of Manhattan, Kan., into the country northwest of that place. The line will be but 3½ miles long, but will connect with long distance lines both east and west. Eventually the promoters of this line expect to extend it farther.

A telephone line is assured for Wapping, Conn. The requisite number of subscribers has been secured. It is expected that the line will be in operation by the 1st of June.

Successful Year for California Independent Company.

The Independent telephone movement in Southern California has been in existence a little over a year. The exchange at Los Angeles now has 9,103 main lines installed and working, 11,732 instruments in use, 400 private branch exchange trunks, 101 private branch exchanges and inter-communicating systems connected directly to central, which have from 10 to 300 lines each. A total of 80-300 pair cables enter this exchange, making one of the largest main distributing racks in the world. The growth has become phenomenal and it has been found necessary to arrange for three branch exchanges to take care of the large number of unfilled orders. A large and increasing business is being done, over 50 toll stations being now connected to Los Angeles. The toll board consists of a two-position desk and another two-position desk is being installed, three more positions are being added to the main exchange, the ultimate of which is 18,000. The longest line entering this exchange and working central energy, is six miles and gives entire satisfaction; the cable portion is probably 4½ miles long.

John Van Lieu is general manager; P. Kerr Higgins, superintendent of equipment, and maintenance, and Fred Hummel, superintendent of construction.

Michigan State Telephone Company.

The statement recently made that a voluntary payment would be made by the Michigan State Telephone Company to the minority stockholders of the Michigan Telephone Company is denied by officials of the former company who state that they have never heard of any such proposition.

News from Chicago states that the charter of the United States Telegraph & Telephone Company has been filed for record with the county recorder. The members of the company are Henry E. Weaver, G. Watson French, Henry L. Turner, Harry D. Critchfield and Harry Rubens. The capital stock of the company is $2,500, and divided into 25 shares at $100 each. Each member holds five shares. The purpose of the company is to construct, own, maintain and operate lines of electric telegraph and telephone in any State, territory or county and to acquire and own everything pertaining thereto.

Bill Brothers, who have just established the new Independent exchange in Lincoln, Neb., are commencing to build an exchange in Sioux City, and are planning to connect the latter city and Lincoln by an Independent long distance line.

The New York & Long Island Telephone Company now has permission to install its system in Babylon, L. I.

The Local Independent Telephone Exchange at Coshocton, O., has concluded to issue $22,000 preferred stock to improve and enlarge its exchange.

The Arrowsmith, Ill., Telephone Exchange has been purchased by Walter Lain.

Sioux City Company Plans for 'Phone Station.

The Sioux City Telephone Company, which is to establish an Independent automatic telephone system in Sioux City, Ia., has fixed September 1 as the date on which the system is to be ready for operation. The plans for this building have practically been completed. It will be of brick and stone and will cost from $20,000 to $25,000. It will be 45 feet wide and 90 feet deep and will have two stories with high floors and a basement, one-half of which will be above the level of the street.

"It is our purpose to locate the building as nearly in the center of the telephone district as possible," said F. G. Bills, secretary and treasurer for the company. "By procuring a site that will be central for our lines as they radiate to the various parts of the city, we will save expense in cable materials, wire and other equipment. Our Lincoln, Neb., system, which we recently finished, was completed in 94 days, and it has about 2,500 subscribers. Here we have thus far about 2,100 names. We have a good deal of material on hand now in the shape of wire, poles, etc., but we want to wait until the poles all arrive before we start our line work."

In Connecticut the telephone companies have established about 6,000 farm stations, and the number is rapidly increasing. At a cost of $18 a year the farmer can place himself in constant and immediate touch with the town and city, receiving market quotations and advices every day, and selling or ordering goods without moving outside of his own home.

Many telephone companies have now entered into partnership with the farmers, and the rural service of a number of the companies is more extensive and valuable than the town service. Better wires are used, superior instruments employed and better general service is maintained all around. The whole country is in a fair way to be gridironed with wires.

The Vanderbilt lines will, within a short time, have a telephone system between New York and Chicago with local exchanges in the different railroad centers between. The line will go through Pittsburg and Youngstown, forming a complete system, independent from the public telephone companies.

A farmers' telephone line to St. Thomas, Minn., is to be constructed by the Cannon Valley Telephone Exchange at Montgomery, Minn.

The farmers in the vicinity of Gresham, Pa., are discussing the question of constructing a co-operative telephone line.

Lines to Manston, Stod and Burau, Minn., are to be built by the Rothsay Telephone Company of that State.

The Rural Telephone Company of Osseo, Minn., will build a telephone line in Hennepin and Wright Counties. Its capital stock is placed at $50,000, but business may be commenced when $1,000 is paid in.

The Otterville-Smithton Telephone Company, of Otterville, Mo., has filed a statement to show that it has made an increase in its capital stock from $2,000 to $5,000.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alma, Ark.—This town will soon be lighted with electricity.

Ballard, Wash.—H. A. Starkey was lately awarded a 50-year light and power plant franchise, and an ice and cold storage plant will also be erected.

Blakely, Ga.—The Blakely waterworks and electric light plant was completely destroyed by a recent fire. The loss is estimated about $10,000.

Bradford, O.—The Bradford Electric Light Company has been incorporated with a capital of $10,000 by A. W. McCune, J. T. Arnold, Nate Iddings and others.

Caldwell, Tex.—More than half the necessary bonus has been raised for the electric light and ice plant, which Cypher Brothers, of Austin, propose to install.

Chatsworth, Ill.—The Chatsworth electric light plant, of which L. A. Walter is proprietor, will make extensive improvements to the plant by installing additional machinery.

Coggon, Ia.—There is a movement on foot to organize a stock company for the purpose of establishing and operating an electric light plant here.

Coronado, Cal.—The tent city is to have electricity installed for lighting purposes in time for the coming season.

Elreno, Okla.—The Union Light & Power Company has been incorporated by H. T. Smith, R. S. Trulock, and E. E. Blake, for the purpose of building, maintaining and operating an electric light and power plant in conjunction with hot and cold water and a gas system. Its capital stock is $150,000.

Leonard, Tex.—The Leonard Electric Light & Ice Company has applied for a charter. The following officers have been elected: Y. T. Manning, president; R. L. Regney, vice-president; L. H. Saunders, secretary; W. C. Evans, treasurer.

Malvern, Pa.—It is stated that this borough wants plans and specifications from engineers for a gas or electric plant. An engineer is desired to look over the ground.

Menomonee Falls, Wis.—This town is making a movement to put in an electric lighting plant.

Pineville, Ky.—The Pineville Electric Light & Ice Company, of Bell County, with a capital of $25,000, has been formed.

Redfield, S. D.—The citizens will vote on the question of issuing bonds in the sum of $7,500 for the refunding of electric light bonds, and also for the improvement of the electric light plant.

Ruston, La.—Mr. Sanders is supervising the putting in of an electric light system here.

Searcy, Ark.—An improvement district has been formed here for the purpose of installing an electric light plant.

Sutton, Neb.—This town is to have an electric lighting plant, and it is to be provided entirely by private capital.

Table Grove, Ill.—The voters have approved a proposition for the purchase of an electric lighting plant.

Waterville, Me.—The Fort Halifax Power Company has been organized here for the purpose of carrying on an electric light and power plant in Benton and Winslow, with $250,000 capital stock. Harvey P. Eaton, of this place, is president.

Williamsburg, O.—C. H. Lochard, mayor, states that bonds for an electric light plant have been sold. Plans and specifications have been drawn and bids will be received for the contract.

Winslow Ill.—There is some talk of an electric light plant here.

Yankton, S. D.—A special election may be held here to consider the issuance of bonds for electric light improvements.

STREET RAILWAYS.

Des Moines, Ia.—The Des Moines Interurban Railway Company has practically perfected plans to build an interurban electric line between Perry and this city, which it hopes to complete this year.

East Troy, Wis.—C. D. Towsley has been securing the right of way on the proposed electric railway over the old line of the Milwaukee and Beloit grade.

Fairmont, W. Va.—The Fairmont & Manningtou Electric Railway Company has been organized here with T. W. Fleming as president.

Hamilton, O.—The Toledo, Columbus & Cincinnati Electric Railway is ready to float bonds and begin the construction of its line.

Hazleton, Ia.—D. B. Lyons, of Des Moines, is the promoter of the Oelwein & Hazleton Construction Company, capitalized at $10,000, to build an interurban railway here and at Oelwein.

Jeffersonville, Ind.—Work will soon commence in converting Capt. E. J. Howard's mule road into an electric line.

Kansas, City, Mo.—The Metropolitan Street Railway Company will erect an additional power plant at the corner of 12th and Cleveland streets to cost $20,000.

Lancaster, Pa.—The Lancaster & Ephrata Traction Company will build a line through Lancaster.

Lewes, Del.—The survey of the Lewes & Rehoboth electric railway was lately started.

Lisbon Falls, Me.—The Rev. Frank W. Sandford proposes to build an electric railroad between here and Shiloh.

Philadelphia, Pa.—The Philadelphia & New York Traction Line announces that its through service from Camden to Jersey City will be begun May 10.

Piqua, O.—Henry Newman, of Fletcher, asserts that the Addison, Piqua branch of the Springfield, Troy & Piqua Traction Line, will be built soon.

Richview, Ill.—Work will soon begin on the Southern Illinois electric railway line.

Roanoke, Va.—H. M. Darnall, of this city, is interested in the new electric railway company being organized at Floyd, which will build an electric line costing $1,000,000.

Sandusky, O.—Work will soon commence on the Marion, Sandusky & Tiffin Electric Railway Company's line.

Topeka, Kan.—The Kansas City, Olathe, Lawrence & Topeka Railway Company has been formed to build a trolley line between here and Kansas City, with a capital of $1,000,000. The incorporators are William B. Strang and James King Duffy, of New York; Alexander Monroe and John N. Roberts, of Lawrence, Kan., and Eben Baldwin, of Lake View, Kan.

Waterloo, Ia.—The Waterloo electric line will be extended to Westfield.

West Liberty, Ia.—This city has granted a franchise to the Iowa City and Davenport Electric Line to use certain streets of the city

POWER PLANTS.

Birmingham, Ala.—A power plant will be constructed for the generation and electric transmission of power. George B. Burd, Erie County Bank Building, Buffalo, N. Y., is interested.

Granite Falls, Minn.—A company has been organized and incorporated for the purpose of improving the Minnesota Falls water power. E. H Sorlein, H. H. Sorlein and Claus Lende, of this place, are interested. Electric power will be transmitted.

Hagerstown, Md.—Capitalists interested in the scheme to generate electricity at Dam No. 5 along the Potomac River, are planning to make the enterprise far reaching, and unless their plans miscarry they will be in position within the next year to furnish electric current to all cities and towns within a radius of 25 or 30 miles.

Red Bluff, Cal.—It is reported that the Northern California Power Company will install a plant at the gas works in this city to generate electric current.

Spokane, Wash.—Money is being raised to put in a large electric plant to cost from $100,000 to $150,000, and a 300 stamp mill on the Palmer Mountain tunnel property in Okanogan County this season. D. M. Drumheller and Dr. N. Fred Essig, of this city, are interested.

Watsonville, Cal.—The Big Creek Power Company of Santa Cruz will purchase five acres of land in this city as a site for a plant to furnish the local circuit with electric power. About $100,000 will be spent in improving the service here

BIDS WANTED.

Baltimore, Md.—Sealed proposals marked Proposals for Electric Lighting in Druid Hill Park, and addressed to the Board of Awards, care of H. F. Hooper, City Register, City Hall, will be received until May 11 for installing and maintaining electric lights in said park.

Effingham, Ill.—Sealed bids will be received until May 17 by the city clerk for the lighting of the streets for a period of 5, 10 and 15 years from November 5, 1904. Address J. S. Johnson, city clerk,

Washington, D. C.—The Treasury Department is inviting sealed proposals until May 10 for installing a system of electric light wiring and fixtures in the United States court house building at San Antonio, Tex. Drawings, specifications and blank proposals can be obtained upon application to the custodian of the building or to the Secretary of the Treasury, this city.—Sealed proposals are invited until May 11, for furnishing the office of public buildings and grounds of this city with electric battery supplies during the next fiscal year. Address Col. Thomas W. Symons.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 13⅛@13¼c.; Lake 13⅜@13⅝c.; casting, 13@13⅛c.

Holders of Twin City Rapid Transit common stock believe they will receive a dividend of 6 per cent.

The Cincinnati Gas & Electric Company will increase its dividend rate from 4 to 4½ per cent., beginning July 1.

At the annual meeting Monday of the New England Telephone & Telegraph Company the retiring board of directors was re-elected.

It is reported that for the first 26 days of April Brooklyn Rapid Transit showed a gain in gross earnings of over $60,000, as compared with the same period last year.

The Michigan State Telephone Company, the successor to the Michigan Telephone Company, has declared the first quarterly dividend of 1½ per cent. upon its preferred stock.

Stone & Webster report that a dividend of $5 per share has been declared on the Tampa (Fla.) Electric Company, payable May 16 to stockholders of record at the close of business May 5.

The receivers of the Chicago Union Traction Company have issued certificates of indebtedness amounting to $500,000 to pay interest on the floating debt and to meet other urgent expenses.

It is reported in Wall street that the Kings County (Brooklyn) Electric Light & Power Company will soon increase its capital stock and then be taken over by the Consolidated Gas Company.

At the annual meeting on Monday of the Philadelphia Company of Pittsburg G. E. McCauge, formerly traffic manager of the Carnegie Steel Company, and John C. Riley, a local capitalist, were elected new directors.

It is reported that the Public Service Corporation, which controls the trolley lines and gas companies in New Jersey will soon begin to sell tickets from Jersey City to Philadelphia. As far as Trenton, the route will be over trolley lines and from there, it is said, that the company proposes to run a line of boats.

It is stated that the Michigan State Telephone Company has arranged with the holders of Detroit Telephone Company bonds, of which there are $600,000 outstanding, on the basis of $480 in new bonds, $265.25 in preferred and $428.75 in common stock and $250 in cash, in lieu of the January interest on each $1,000 bond assenting.

The action of Governor Bates of Massachusetts last week in signing the bill permitting the Boston & Northern and Old Colony Street Railway Companies to issue a blanket mortgage upon their property paves the way for the financing of the Massachusetts Electric Companies this year without resorting to a stock issue, which, with the preferred stock selling at 73, or 20 points under the selling price of the last $5,000,000 preferred stock issue, could not now be placed to advantage.

For the payment of the assessment of $2.50 per share on the stock of the Philadelphia Electric Company the books will be closed May 20 at 3 P.M., and reopened June 17 at 10 A.M., for the June payment, and closed November 19 at 12 noon and reopened December 17 at 10 A.M. for the December payment. No transfer will be made of any certificates upon which the payment of any installment which is due and payable has not been made. Stock certificates must be presented when payments are made in order to have the same indorsed properly thereon.

ELECTRICITY.

VOL. XXVI. NEW YORK, MAY 11, 1904. NO. 19.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone. 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.......................... 3.00
Single Copies..........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

EDITORIAL NOTES.

A Fortune in Car Fares.

A report made public last week by the New York State Railroad Commission, regarding the number of passengers carried on the railways of Greater New York, is extremely interesting and shows what up-to-date electric traction is capable of doing.

The report shows that for the year ending February 29 car lines in Manhattan alone carried 670,000,000 passengers, exclusive of transfers.

This is more than 100,000,000 more passengers than all the steam railroads of the United States carried in the same period, their record being 568,000,000 passengers. In Greater New York more than one billion passengers were transported.

While there was the enormous gain of more than 37,000,000 passengers on the elevated lines during the year the surface lines had only a trivial increase. This is explained by the fact that the New York City Railway Company in operating the Metropolitan Company's street car lines has reached the limit of its capacity. It can provide no further accommodations.

On the surface lines the total number of passengers for the year was 397,644,829, an increase of only 144,311.

Much more promising was the report of the Interborough Company, operating its elevated lines with its longer trains and new electric system. It carried in all 273,133,242 passengers, an increase over the previous year of 37,318,852.

Transfers in Manhattan amounted to 166,000,000. The Union Railway Company carried in the year 21,273,870 passengers, an increase of 1,998,543 over the year 1902-3, which was 19,275,327. With transfers the total number carried was 21,698,501. In the Bronx, all railroads, the total number carried for the year was 22,147,077, an increase of 1,988,636.

In Manhattan the total car mileage of the Interborough was 60,730,337, an increase of 12,870,859 over the previous year. The car mileage of the Metropolitan system showed a total of 62,412,527, a net increase of 954,666.

In a recapitulation for the Borough of Manhattan a total of 670,778,071 passengers carried in the twelve months is shown, an increase of 37,463,163 over the previous twelve months.

In Brooklyn the Brooklyn Heights Railroad Company, which is operating the Brooklyn Rapid Transit system, carried 285,725,986 passengers, an increase of 25,280,425. Transfers amounted to 55,146,001. Car mileage was 54,394,315.

By the Coney Island and Brooklyn Railroad Company 33,129,812 passengers were carried. The total number carried in Brooklyn on all lines was 320,107,163. In Queens, passengers numbered 16,058,-207. In Richmond, on all the roads, 7,744,255 were transported.

In the Greater City the total of passengers on all the lines was 1,036,834,773, which means that the citizens of the metropolis spent last year $51,841,738.65 for being carried to points within the city limits.

* * *

The Design of the Modern Power Station.

The salient features of an electric generating station for power supply, whose design rendered all other considerations subservient to the commercial success of an undertaking as a whole, were discussed in an exhaustive paper which came before the London Institution of Electrical Engineers on Thursday, April 28. The authors, Messrs. C. H. Merz and William McLellan, are consulting engineers who have been associated with some large English generating systems, and many of their observations were the outcome of practical acquaintance with the

design of these works. They omitted particular reference to electric generation from waste products and by water power for obvious reasons—water power being very limited in its English applications, and waste products and their utilization being of sufficient interest to claim a separate paper in order to assure for it an adequate treatment.

Though it may be true that in the past few years engineers have recognized that cheapness and reliability of supply are the main factors controlling the commercial success of electric light and power plants, it is contended that if a station for power supply were designed on similar lines to many existing stations "commercial failure would almost certainly result." To insure reliability of supply, which must really take precedence over everything else, even over economy of production, the governing general principles which must be kept in view are: Simplicity of design, sub-division of plant and apparatus, labor-saving devices and provision for extensions. The complication which existed formerly when station engineers seemed to regard breakdowns as inevitable, and when they devoted attention to minimizing the effect of mishaps rather than to reducing the amount of apparatus in which a breakdown would occur, now appears to be diminishing. To obviate risks of complete shut-downs, due to the failure of a steam pipe, the boiler-house plant must be sub-divided into a series of groups. Indeed it is imperative in a large power station to sub-divide all parts of the apparatus, from the boiler-house to the switchboard, into a series of units, each complete in itself. This is essential in order to obtain reliability of supply, and yet is in no way inconsistent with economy of production. Endless trouble may follow the crowding together of all kinds of water and steam pipes in one trench; and in the same way endless trouble with switchgear may result from fixing many cables or connections for different purposes, either on one panel, or in one partition, or in one trench, as the case may be. In regard to labor-saving devices, the adoption of such apparatus may either increase or reduce the reliability of supply, and before expending money upon them the pros and cons of a case should be systematically considered.

In respect of future extensions, power stations for wholesale supply, if the eventual capital expenditure per unit sold is to be kept down, "must not be designed for to-day;" there is nothing which increases the station capital account so rapidly, and prevents that gradual decrease of capital expenditure per unit sold which should take place with the growth of a system, as alterations to existing work, and rearrangements in order to meet increased output. In deciding upon general arrangements, or the position of any particular piece of apparatus, or the size of any pipe or trench, it is essential to consider whether such decision is likely to affect, or to be affected by, future extensions.

After elaborating at some length upon the main principles governing power station design, Messrs. Merz and McLellan proceeded to discuss some of their effects on the actual design of a station for the supply of three-phase high tension current at 5,000 volts or over. Steam turbines of any type were regarded as being possessed of great advantages over reciprocating engines, on both counts, reliability and economy, and curves of steam consumption obtained from a 1,500 kw. to 2,000 kw. turbine installed at Wallsend power station between two and three years ago were advanced in support of the latter effect. The set ran 7,500 hours without ever having been opened up, and only on two occasions had the bearings needed any re-setting in order to keep the clearance correct, although they were three times examined and the clearance tested. In fact the only faults of any kind which it was ever necessary to repair were the relining of one of the governor throttle valve chests and the renewal of an oil disk.

The authors admitted that the high thermal efficiency of gas engines has long rendered their use attractive to power station engineers, but they have not so far attained the same perfection as the steam turbine; and they contended, in discussing the general question of the steam turbine, that its use "simplifies the remainder of the power station and generally the system as a whole." One of the arguments made use of was this: "Of course such improvements in gas engines may be made as will result in their superseding steam turbines, but if the advocates of gas engines are correct in stating that the present type of gas engine is being rapidly improved upon, it is the more advisable to install at first a cheap plant in order to diminish the cost of superseding it when gas engines approach finality in development."

It was suggested that a very great saving in the total cost of production could be obtained by paying proper attention to the following points: By correctly apportioning the spare plant for each piece of apparatus making up a complete unit; by correctly apportioning the overload capacity of each piece of apparatus; by designing the plant so that the economical rating of each component is identical, and by relying upon the overload capacity not only for dealing with sudden emergencies (say a shut-down of one of the units that may happen to be running at the time), but also depending upon it for the ordinary peak load of the station, or when other plant is being overhauled.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

The regular meeting of the Ohio Society of Mechanical, Electrical and Steam Engineers will be held at Columbus, May 13 and 14.

The Canadian Geological Survey reports the Dominion's output of copper for 1903 as increasing about 11½ per cent.

In Vienna, Austria Hungary, telephone call boxes are provided with napkins, bearing the request, "Wipe if you please." The practice of wiping the mouthpiece of the transmitter is a sanitary precaution.

The observation tower at Coney Island, which is 375 feet high, is to be illuminated by 33,000 electric lights.

It is now stated that the Rowland Printing Telegraph system, which has been on trial for the past year in Italy will be adopted by that Government.

Advices from South Africa state that a movement is on foot to electrify a section of the Central South African Railway between Springs and Krugersdorp, also some $400,000 is to be expended in the construction of an electric lighting system at Port Elizabeth, Cape Colony.

Electricity is to be used as the motive power for the grape crushers in Livermore, Cal.

The Government has a contract with the De Forest Wireless Telegraph Company of New York, for the use of its system along the chain of Great Lakes, and 35 stations will be established at important points. The entire service is expected to be in commission before next fall, the first link, that between Buffalo and Cleveland, already being in working order. One station will probably be at the Soo, another at Marquette, a third at Portage Lake (Keeweenaw Peninsula) and a fourth at Duluth, with the probability of a fifth between Portage Lake and Duluth and still another between Marquette and the eastern end of the lake.

THE LATEST PROGRESS IN WIRELESS TELEGRAPHY.

BY EMILE GUARINI.

Translated for "Electricity" by Jean A. Wetmore, M. S., E. E.

(*Concluded from page 244.*)

It is desirable to choose the type of transmission in accordance with the detector employed, and also bearing in mind the purpose in view. The practicable statements of M. Ferrie on this subject merits a restatement.

If detectors are used which integrate the energy received during a series of discharges by a receiving antenna (thermic and hysteresis detectors, etc.), the oscillatory devices, slightly deadened, will give the best output, because the total amount of energy received is considerably greater.

When, on the contrary, we use detectors which are sensitive to the maxima of instantaneous energy corresponding to maxima of tension, such as coherers, it is much better to employ direct oscillatory apparatus on account of the very brisk

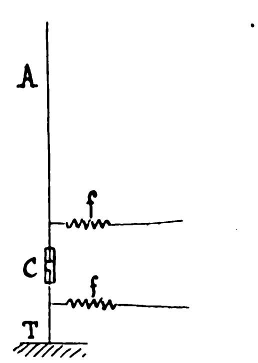

FIG. 19.

variations produced by the shocks of each discharge.

On the other hand, if in the latter case we obtain much greater distance effects, we find that the non-attuned receivers are much more easily operated, and may be annoying in certain instances, nevertheless coherers alone, as we know them up to the present time, allow of the registration of the discharges.

Furthermore, it is found that harmony may be secured, especially with coherers. If it is desirable to obtain it slightly deadened waves must be used. M. Ferrie states that it is necessary to employ antenna in transmission devices, which, taking into consideration the losses, have a lesser effect upon the coherer.

As coherers are almost wholly employed in all wireless telegraph installations, M. Ferrie has classified the various devices, dividing them as follows:

First—Apparatus which is directly acted upon (Fig. 19). The coherer is inserted in the antenna circuit A, which latter may be considered as being insulated by the coherer C and the self-induction f. If the transmitting wave length is attuned to the receiving antenna (the latter being considered as grounded direct) the effect produced by the presence of the coherer will be to double the period of the antenna, since the latter is insulated by it. The action would consequently be very feeble, but in reality the presence of the coherer extends the period of the antenna itself as a result of the capacity of this

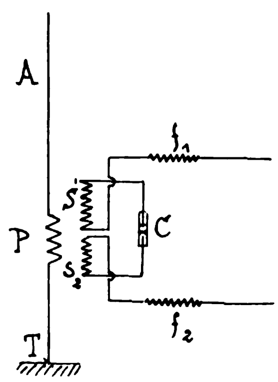

FIG. 20.

instrument. Again the vibratory movement, which is set up in the antenna, effects partially the self-induction f, and the period is thus again lengthened out by this cause. It is to be noted that signals may be received by this process from considerable distances.

Second—Induction apparatus (Fig. 20). This class of apparatus requires a tuning to make it correspond to the transmission wave periods, connecting first with the receiving antenna and then with the circuit which acts upon the coherer. The harmonizing of the receiving antenna is easily accomplished by making it identically the same as that of the transmission, if it is possible to do so, and if it be not possible, the form or the number of wires in the antenna may be modified until the wave lengths become equal to that of the given transmission.

The primary of the transmission ("jigger") is inserted in the antenna circuit, which latter is of short length (about 2 meters) and having a small number of coils, so as not to appreciably change the period of the antenna. It is better to insert these coils in the antenna circuit as near the earth as possible, because the intensity of the oscillations at this point are at their maximum. The secondary is divided into two portions, S^1, S_2, each respectively connected to two self-inductions, f_1 f_2, and to the terminals of the coherer, so we then have to consider two distinct circuits, S^1 f_1 and S_2 f_2.

To harmonize them it is necessary to so establish these circuits that they will have a maximum tension at the extremity of each of them connected to the coherer; but by referring particularly to the works of M. Perrot on the propagation of Hertzian waves in long wires, we must admit that each of these circuits are to be always closely adjusted, whatever the excitation period may be, within certain limits. In fact the stationary waves, which are set up by reflection at the extremity connected to the coherer, are automatically taken up by the self-induction as a result of the deadening of the propagation, whatever their length may be.

We should give to the secondaries, S^1 S_2, a sufficient length at the start from the point where the primary acts (which is always wound upon and wound around both the near extremities of the two half-secondaries) so that it may be able to produce at the extremity connected to the coherer an elevation of tension, in order to secure the Oudin effect. The tensions produced at the coherer terminals of the circuits are of opposite polarities, which results from the direction of the windings.

We are able in practice to easily construct the "mean jigger," that is to say, the transformer, which gives the best results, whatever the transmission wave length may be, from 100 meters up to 1,000 meters, but this is not always the best in every instance. The increase in length, which S^1 S_2 must undergo, so as to obtain the maximum results, are feeble, being of a few turns only.

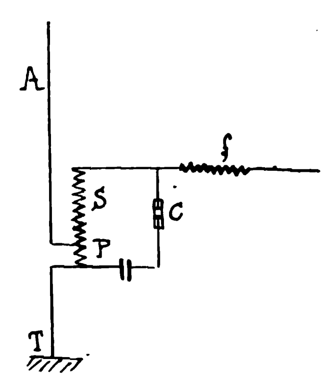

FIG. 21.

It is interesting to note here that the capacity of the coherer is a factor in harmonizing on account of its increased length. Mr. Marconi connects each of the extremities of a condenser to the interior ends of S^1 S_2, but M. Ferrie observes that experience shows that it is of no value.

Third—Derived circuit apparatus. It is necessary to tune up these devices the same as the preceding, i.e., the antenna is made to harmonize with the shunt circuit (Fig. 21), the stationary waves, which are produced in the derived circuit and still drowned in the self-induction f (which is made up of the relay coil in accordance

with the arrangement devised by M. Slaby). But as the coherer must be placed in a tension curve it is important to exactly regulate the length of S, so that this maximum shall be exactly placed at the derived point of the coherer and not any further in the self-induction.

Consequently with this apparatus it is not as easy to construct the "mean jigger," as more accurate adjustments are necessary in each case. This is a good point in this process, but on the other hand the carrying effect must be less, because one terminal of the coherer is at 0 potential, on account of its being connected to the ground, and consequently the single terminal only is at a maximum tension, but the one tension, which it can have, appears to be considerably more than that obtained through induction in the preceding case, for the losses must necessarily be considerably less.

M. Rochefort has attempted to overcome these last mentioned defects by operating in the following manner (Fig. 15): He employs a bipolar resonator (S_1 S_2), and the antenna oscillations determine the production of the two maximum tensions, having opposite polarities at the extremities of S_1 S_2, which are connected to the coherer, but this device requires the use of a coherer of three electrodes, i.e., two coherers in series, for the purpose of preventing a short circuiting of the battery. The advantage resulting from the production of two such tensions must consequently be counterbalanced by a diminution of the coherer's sensitivity.

In this respect we cannot say we agree with M. Ferrie. From the fact itself that M. Rochefort uses a two-chambered filing coherer in series he is thus permitted to place two batteries in tension in circuit with the coherer in such way that the sensitivity of the coherer remains the same. In other words, the advantage which M. Ferrie attributes to the use of the Rochefort devices exists, but not the disadvantage.

M. Ferrie further states that with the Rochefort devices the "mean jigger" cannot be constructed, for it becomes necessary to exactly harmonize S_1 S_2, so as to get a maximum of tension at the extremities. This device consequently appears to give absolutely analogous results to those obtained by M. Slaby, we will add, with the difference that here we have a double tension, i.e., that we can attain a much greater carrying distance with a given amount of energy.

Fourth—Compound devices, derivation and induction combined. M. Ferrie has employed for several years a device in which he has attempted to unite the advantages secured by both the induction and shunt devices (Figs. 22 and 23).

The coherer is operated on by two tension curve waves of opposite polarities, one of which, S_1, is obtained by derivation, and the other, S_2, by induction.

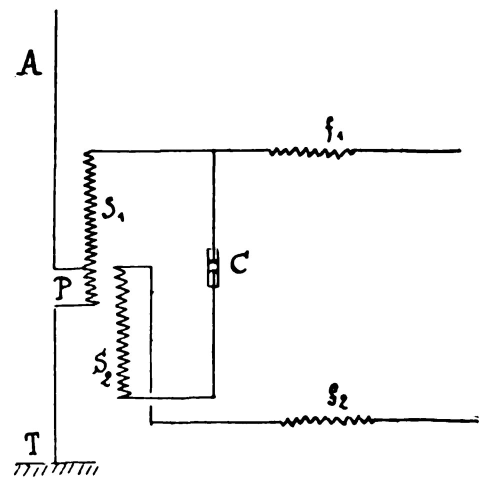

FIG. 22.

The theory stated in the preceding cases still prevails. The two devices (Figs. 22 and 23) are almost equivalents. The one in Fig. 22 may be derived from the induction apparatus (Fig. 20) by joining the interior extremities of S^1 in the latter to the earth terminal.

To sum up, as a result of the preceding discussion, to obtain the maximum operating distance with a station (a ship for example), whose wave length is not known, it is desirable to use a direct excited transmission apparatus, that is to say, a device which is in general public use, as we have shown in the *Scientific American Supplement* of April 25, May 2 and 9,

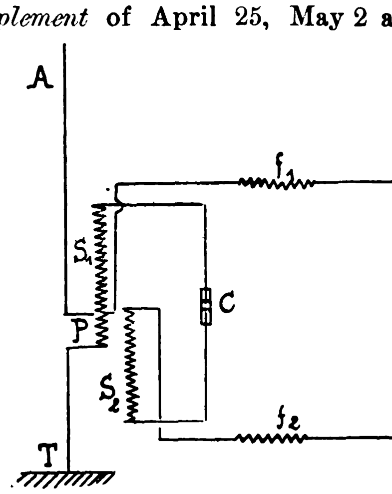

FIG. 23.

1903, and for receiving induction apparatus (Tesla 1897) or a compound device in place of Popoff direct. But for the purpose of communicating with a known station, with the least possible annoyances to the stations which may be in the near vicinity, it is preferable to transmit with an induction apparatus and to receive by means of a derivation or a compound apparatus. The transmission should be more energetic if the receiving is done through derivation, for the sensitiveness of receivers in this class of apparatus is less than with the compound devices, but whatever kind is employed for transmission and for receiving, it is impossible to obtain independence in these transmissions, or in other words, to have simultaneous service in two neighboring stations.

This does not seem to us to be admissible without restrictions, for if, as we have clearly stated, the solution of syntonization can never be absolutely accomplished, the problems regarding secrecy of the dispatches and of the non-interference between stations, it is incontestable that Marconi and Slaby have practically demonstrated that at least, under certain favorable conditions, it is possible to solve these problems and likewise that of multiple transmission.

After the preceding considerations, M. Ferrie took up the matter of the applications made, and he mentioned relative to transatlantic attempts: "The purpose does not appear to have been accomplished." He has cited the American, English, German and Italian installations. Relative to the German, we have just learned that there are already about 250 Slaby-Braun stations, which during the middle of January, 1904, were in operation in various parts of the world, and besides 69 other stations are in process of construction.

M. Ferrie stated that the use of wireless telegraphy in public service in France has shown itself to be very prudent, and outside of its application to the marine, military and war requirements, there has not been made up to the present day, a single installation open to the reception of private telegrams; the installation connecting Martinique with Guadeloupe is very soon to disappear, as the cables have been recently repaired. However the experiment can be considerered as conclusive, and it is probable that new installations will be undertaken at various points. M. Ferrie has been until recently a very great sceptic in respect to wireless telegraphy, which is encouraging for this new kind of communication. He, however, concludes that it will always be of advantage to install a wire between two points which are to be telegraphically connected every time that it is possible to do so, wherever the expenses of doing so are not disproportionate to the prospective income. But we will add, how many countries are there, even in Europe, which can meet such conditions? What must we then say in regard to other continents?

M. Ferrie states that the applications of

wireless telegraphy are consequently not possible on land, except for the requirements of defense or for the colonies.

This appears to us to be saying too little; what, then, is to become of the special applications, such as fire alarms, intercommunication between moving trains, etc.? M. Ferrie's remarks appear to be made from a French standpoint only. Why should wireless telegraphy be of service to the colonies and not in new countries, such as the Congo and South America, etc., where it is difficult, and even impossible, as we have seen in the Congo, to install and above all to keep up wire lines?

On the other hand it may be advantageously employed, as M. Ferrie states, to connect islands with continents, to communicate between boats, and between them and the coasts, with reservations only that the stations are to be sufficiently far from each other, so as not to mutually interfere. Applications of this kind increase from day to day to such an extent that an international understanding has been recognized as being necessary for maritime purposes. The first conference in this respect was mapped out last August in Berlin relative to the preliminaries of a convention for the purpose of submitting technical regulations and to furnish service to all the coast stations which are open to private service.

Although attempts have already been made to build up a monopoly in favor of this or that company, everything leads us to believe that the field will remain an open one for all the systems of every nationality. This appears to us just, although it is true that even though Marconi be the pioneer in wireless telegraphy, it is likewise true that the present devices employed are as a whole the results of work of several inventors.

It is our sincere hope, M. Ferrie states in conclusion, that a new incentive will result from this convention, which will favor the discovery of the necessary improvements in wireless telegraphy, to give to this new means of tele-communication all the safety and convenience in its use which its predecessors have possessed.

M. Ferrie admits that in a future more or less distant wireless telegraphy may be able to attain all the perfection now found in ordinary telegraphy. This is saying considerable, if we recall M. Ferrie's statements on several occasions and even during the course of his present address. In comparing wireless telegraphy with the history of ordinary telegraphy we are practically guaranteed the future success of telegraphy without conductors; we are able to foresee a much larger field for its application and that it will greatly contribute to bring the people of the earth closer together.

ELECTRIC WINDING ENGINES.*

BY MAURICE GEORGI.

Up to the present time in England electrical winding engines are practically unknown, although on the Continent, especially in the mines of Silesia and Westphalia, they have during the last few years made rapid headway. The modern steam winding engine is well adapted to all the demands of the service; it nevertheless absorbs an immense quantity of steam, as the effort is never constant, and therefore the admission in the cylinders is essentially varying. For instance, in starting his machine the driver has to open his stop valve completely, giving full admission in order to shorten the acceleration period. After a certain number of turns of the engine the haul is finished, and he has to stop his machine by using his brakes or giving counter steam to the cylinders; thus the whole of the kinetic energy of the system is lost in the brakes. Should a load be lowered, as is often the case, we possess no means of turning to any practical use the work done by the engine, the liberated energy having to be constantly absorbed by the brakes.

If we now turn to an electric winding engine we find that its first advantage is to diminish very considerably the coal consumption, which can be brought down to about one-third of its original value if a modern generating plant is adopted. Steam turbines, superheated steam, variable expansion, and gas engines fed by producer gas cannot be utilized by the present winding engines, but all are now at our disposal, and as it is now possible to maintain an absolutely constant load on our machinery, an entirely new set of conditions is arrived at in the arrangement of our power-house plant.

Considering that the work done by winding machinery is of the most intermittent character, the torque to be overcome at the beginning being sometimes more than double that during the haul (owing to acceleration), it will be necessary, should no special contrivance be used, to calculate the steam engine driving our dynamos to enable it when starting up to overcome the corresponding torque; and, on the other hand, it must work with an economical admission during the haul and whilst the winding machinery is at rest. These conditions are, as a rule, incompatible, so that engineers have been led to invent means by which energy should be accumulated whilst the winding engine is at rest, this energy being given up whilst working, so to have as far as possible a constant admission in the cylinders, and consequently a high working factor. If we use continuous current our mind is at once led in the direction of a storage battery. This system, so far as theory is concerned, gives a perfect compensation should the battery be properly calculated, but it does not do away with the starting resistance, although the machine can be started in an economical way by a complicated battery sub-division, the motor being grouped on to various combinations of cells.

The disadvantages of such a method of operating are at once apparent; the complicated and delicate electrical contrivances, together with the inherent disadvantages of storage batteries, more than compensate for any gain which may be obtained in efficiency of operation.

On the Continent numerous electric winding engines, and some of considerable importance, have been designed after this system, but have not proved themselves suitable for the operations they had to perform.

There are fortunately, however, other methods, using mechanical means of compensation, which achieve the same purpose by means of massive fly-wheels coupled on our prime movers.

As far as safety is concerned, the conditions that will have to be realized are:

1. The utmost security of working, as winding engines are not only used for the extraction of minerals, but also for transporting men.

2. The speed of the machine will have to be regulated independently of the load —that is to say, independently of the current in the armature, and with the utmost possible economy.

These conditions, especially the second, can be said to have been solved in a satisfactory manner by a new system of compensation discovered by Herr Ilgner, of the Donnersmarckhutte.

The system is based on the well-known fact that a direct current shunt-wound motor with field of constant intensity, and fed by an independent source, will run when an EMF. is applied to the armature terminals with a speed directly proportionate to the voltage, and to the number of turns on the armature. Therefore, if we arrange a continuous-current dynamo with independent excitation, whose voltage can be regulated from zero to a positive or negative maximum by means of a field resistance, a motor

*Abstract of paper presented at a Glasgow meeting of the Institution of Electrical Engineers.

coupled on the same circuit, and having a constant field, will run at a speed varying between zero and a positive or negative maximum.

The starting of the machine is thus most economical, and at any time the power consumed is only equal to the product of the voltage by the current.

To compensate the variations of power required, Mr. Ilgner adopts the following device:

The current taken from the supply drives a converter, composed of a motor, a continuous current dynamo, and a heavy fly-wheel.

An automatic slipping device is fixed to the motor by means of which, should the dynamo call for power, and, therefore, the current in the motor have a tendency to augment, the slip is increased, the fly-wheel giving up kinetic energy. The reverse operation occurs if the dynamo gives no more power, the current in the motor then being used only to bring the speed of the fly-wheel from its present speed to its maximum. The weight and speed of fly-wheel are to be calculated so that for a given slip the output of the motor should remain the same.

Thus the winding engine, as far as the supply station is concerned, may be considered as an ordinary motor of constant output, and treated accordingly.

That the speed is practically independent of the load lies in the fact that we have to do with a shunt motor. This is a most important advantage, possessed by no steam or electrically-driven engine, that to one position of the controller lever corresponds but one speed.

Another advantage is that the machine can be always very economically stopped in the following manner:

Let us suppose that the machine is running at full speed corresponding to the maximum voltage; if we draw the controller lever backwards the voltage of the dynamo will drop, but that of the motor remains the same, so that current will go from motor to dynamo. The system is thus economically stopped, as the recuperated energy is sent from the dynamo through the fly-wheel and motor back into the supply mains. The brakes are absolutely useless excepting for holding up the machine.

If we turn to the actual economy of the system, we find it in no way inferior to that of the very best of other known methods. No starting resistances are used, the energy recuperated at any time is sent back into the line, and the working factor of the fly-wheel is nearly equal to unity.

The current from the dynamo of the converter is carried, without interposition of any switch or fuse, to the winding motor. In this manner no sudden stoppage of the electric supply to the winding motor is likely to occur; the safety appliances are practically useless, as the machine cannot be overloaded, and a short-circuit due to defective cableage is always noticeable immediately. The field magnet exciting current is produced by a small dynamo on the shaft of the converter.

Now, it is of absolute necessity that the voltage of the terminals of this motor should remain the same whatever its speed may be. To produce this, we place a very small dynamo, series wound, next to the exciting dynamo. The current of this auxiliary dynamo passes through windings on the poles of the dynamo, having a demagnetizing effect; thus the fall of speed of converter will have no effect on the voltage, as the loss in turns will be compensated by a stronger field, the current in the auxiliary dynamo diminishing.

The mechanism is so designed that it is absolutely unnecessary for the attendant to pay any attention to slowing down his machine; the apparatus does it for him, and also stops it should he be unable to do so. Moreover, the attendant cannot start too suddenly.

The maximum speed can never be exceeded; a special speed controller is therefore utterly useless.

The sudden stoppage of electric energy from the main does not jeopardize in any way the good working of the engine, as the kinetic energy contained in the fly-wheel is more than sufficient to complete several hauls.

ELECTRICAL STATION PRACTICE.

ARTICLE XXXVI.

BY W. H. RADCLIFFE.

(Concluded.)

The supervision and control of an electrical station is in the hands of the general superintendent or manager. The attributes that must necessarily be possessed by the modern superintendent to render him competent to fill this position successfully, constitute an important feature of electrical station practice, and the presentation of them will conclude this series of articles.

In general, the key to success is an intimate knowledge of the local conditions and requirements. No two stations or plants are precisely alike, and it is the man who knows his station as a small boy his pockets and who keeps constantly in touch with the community, that can make a success of the enterprise. In addition to this the superintendent must be endowed with the necessary amount of practical experience and of technical knowledge, he must also possess executive ability, strict integrity, and good moral character; these fundamental qualifications, together with others, will be discussed in detail later in this article.

The problem that frequently confronts the new superintendent is this: Given an electrical station equipped with old apparatus and machinery, how best to increase the net earnings of this plant without making any radical changes in the equipment? Thousands of dollars have probably been invested in the installation and to throw this away at the start and spend still more in purchasing an entirely new equipment, is usually both injudicious and impracticable. The new superintendent should therefore make up his mind to content himself temporarily with the conditions as they exist, but he should investigate the situation thoroughly so that when he has a certain amount of money at his disposal he will be able to make the most necessary additions and improvements to the plant. It must be remembered that when such additions and improvements are to be made, they should conform with modern practice and be such as to reduce to the greatest extent the cost of current production. The superintendent should not, however, be prejudiced in favor of any one machine, system, or manufacturer, but should investigate thoroughly the respective merits and defects of each relatively to the case in hand, he must also consider in this connection, the requirements that a future growth of the station would necessitate and base his selections accordingly. Having given the matter due consideration, he will be in a position, when the opportunity presents itself, to lay before the directors a clear statement as to the best kind of machines and apparatus to install, their cost, and the profit that will arise from their installation. If his suggestions be acted upon, and his judgment be such that the additions and improvements when made result in an increase of business, he will soon have more money at his disposal, which in turn should be directed toward still further alterations and extensions of the plant,. Gradually, the transformation of the station will thus be brought about, and when satisfactory conditions are once secured every effort should be made toward the maintenance of them.

The station superintendent must of

necessity be a man of many parts; not only must he be perfectly familiar with the operation of the different types of electrical machines and apparatus and of the steam portion of the plant, but he must also thoroughly understand the various overhead and underground systems of distribution. It is equally necessary that he keep posted as to the various applications of electricity to daily life so that he be in a position to introduce or develop business along these lines, thereby increasing the revenue of the station. To be successful he must also be a good business manager. This point has heretofore been overlooked in the engineering courses of technical schools, and the graduates have in consequence often found themselves at a disadvantage in assuming charge of electrical stations. The fierce competition and the small margin of profits which have become prominent features of electrical station practice during the last few years, necessitate the general adoption of the most improved business methods. The station superintendent therefore requires some commercial training; he should be familiar with bookkeeping and with all the details of estimating costs, taking stock, controlling correspondence, and other affairs of a similar nature. Without this knowledge and the ability for organization and management, he cannot successfully perform his duty as superintendent even though he has had both technical training and practical experience in engineering subjects.

The real value of a superintendent to the company by whom he is employed may be said to depend more upon his executive ability than upon any one of the other attributes with which he may be endowed. It is here presumed that a man of good executive ability is himself an excellent judge of human nature, and that he will therefore be able to select and surround himself with subordinates from whom he will obtain the best results with the least expenditure of his own energy. He will of course appreciate the fact that "the laborer is worthy of his hire," and that to obtain and hold good men it is necessary to show his appreciation of them by paying them what they are worth, and advancing them to higher situations when vacancies occur or new positions are opened. Such recognition of able and conscientious service will bring good returns; if, however, promotions are not feasible, a word of appreciation now and then for services faithfully rendered will not usually fall upon stony ground. If the superintendent has himself risen from the ranks so much the better will be understood the conditions of the workmen, and they in turn will hold him in higher esteem if he possess a practical knowledge of the details of their work; he will also be in a position to estimate more accurately the actual value of each class of labor, and therefore to gauge the wages of the workmen accordingly.

The superintendent should not be averse to coming in personal contact with his subordinates, for it is necessary that he know his men to the extent of being able to rely upon them for the proper performance of their duties. It is also in this way that he can best learn of the characters of his employes, and he may possibly receive from them many valuable suggestions; he must, however, be careful to maintain his dignity at such times lest the prestige of his high office be lost. The instructions given by the superintendent to his subordinates must in every case be worded plainly so that no doubt may exist in the minds of the employes as to the proper execution of them; they should, furthermore, be of such a nature that they may be enforced to the letter. Under no conditions must favoritism be shown, and social or political influence should not be considered in the proper enforcement of the rules and regulations of the station.

Inasmuch as the superintendent represents the company before the public, all complaints arising therefrom are brought to him; it is therefore quite necessary that he be sufficiently versed in law to know the liability of the company in case of accidents, and also the rights of the company together with those of the public, under the charter granted. Equally important is it that he familiarize himself with the laws relating to the employment of labor, with the best forms of contracts and specifications, and with the liability of the company in case of injuries to its employes. Legal troubles are liable to arise at any time in the operation of an electrical station of appreciable size, and it is the superintendent who is familiar with the matters previously mentioned that will then be in a position to best protect the company's interests.

The technical training that must necessarily have formed a part of the station superintendent's education is the foundation upon which he builds with material derived from observation and experience. His training should be that of a mechanical and electrical engineer, but in most technical schools the necessary mechanical subjects are included in the electrical engineering course and this course requires from three to four years of study depending upon the educational standing of the man upon entrance. Although more or less experimental work is done in connection with an electrical engineering course at a technical school, it will generally be found to differ considerably from actual working conditions, and it is therefore advisable to afterward supplement the theoretical training thus received with practical experience in some electric light or power station. The length of time required to become thoroughly proficient to assume the position of station superintendent depends altogether on the ability of the man. As in other sciences, those naturally inclined require less time and achieve a more marked success than those whose abilities lie in other directions. The position is such as to require a person possessed of large mental capacity and of a resourceful nature. Problems of an unusual character frequently arise in the operation of a station, the solutions of which cannot be obtained by the application of any cut and dried rules; it is then that the skill and the resourcefulness of the superintendent becomes of particular value in securing satisfactory results. Not only is this true of the solutions of problems which are clearly presented, but it also applies in many cases to the exact conclusion whereon the problem itself is formulated.

In this age of electricity the rapid progress which is being made yearly—nay, monthly, and one may almost say weekly—along electrical lines renders any book on the subject which previously may have been studied in acquiring technical training, more or less out of date; indeed, the same may be said of many electrical books during their passage through the printing house and bindery. It is therefore necessary for every person who desires to keep thoroughly informed and up-to-date on matters relating to improvements in machines and apparatus, together with the best modern methods in station management, as every station superintendent should be, that he subscribe for and read the electrical magazines. By so doing he will keep informed of the ideas of men prominent in his profession, their ideas in the majority of cases being formed either from close observation or from actual practice.

Following the technical training, or if possible contemporaneous with it, should come the practical experience. Practical experience without technical training is hardly sufficient in this age to equip a man for the position of station superintendent. Admitting that experience is a good teacher as far as it goes, it is nevertheless true that many a company has lost many a shekel through a technically

incompetent superintendent, and not infrequently human lives have been sacrificed at the altar of ignorance. As previously stated, the necessary practical experience can well be acquired in some electric light or power station. A number of our largest and best electrical manufacturing concerns also have regular channels through which one possesses a technical education and being fortunate enough to enter can secure much valuable experience in the design and construction, together with the testing and operation, of the various classes of electrical machines, apparatus and appliances. In acquiring this practical experience, the technical training already received is put to test and is thereby impressed more forcibly upon the mind, tending in consequence to develop a sense of self-reliance and of rapid discernment in cases of emergency. The superintendent will not therefore be so liable to become confused when compelled to attend to several important details at a critical moment, and the confidence thereby established in his ability among the employes will give him a certain prestige among them that will react toward his welfare.

Lest the prestige mentioned in the last paragraph develop into self-conceit and as such interfere with the relations which should properly exist between the superintendent and his subordinates, it will be well to state that egotism on the part of the former party will not only react toward his welfare but on the other hand will seriously impede his progress. In order that willingness and hearty cooperation characterize the efforts of the employes, it is quite necessary that they be treated gentlemanly and yet governed in a calm effectual manner. This often requires considerable patience and perseverance on the part of the manager, but the man who is lacking in these characteristics has not the natural ability of a station superintendent. Better far would it be for him to seek calmer channels and less trying situations in which to direct his efforts, for there are many instances in the supervision and control of an electrical station where patience and perseverance are the only means whereby the superintendent can work out his own salvation.

The best means of judging the actual worth of a superintendent to his company is from a profit-making basis. In order that the net profits from any given installation be a maximum, the corresponding costs of operation and maintenence must be a minimum. Of these costs, the former is naturally the larger, and therefore the most important to keep within reasonable limits. To facilitate this work it is advisable to have the various accounts of the station properly divided and subdivided, and the items in each reduced to a kilowatt-hour basis. Comparisons can then more readily be made with the corresponding costs in the operations of similar stations, and from these it will at once be evident in which direction efforts can most consistently be exerted toward the reduction of operating expenses. Having decided upon the object of attack, the superintendent should at first make himself perfectly familiar with the conditions as they exist and then strive to improve them to the best of his ability. The introduction of modern methods and of labor-saving devices which have been upon the market sufficiently long to have proved their standard worth, will go a great way toward attaining the desired result. To reduce the cost of maintenance it is quite necessary to have frequent inspections made of all the machines, apparatus and appliances in the entire installation, and the results entered in proper form upon report blanks. If it be made customary throughout the plant to have the slightest defect noted on the report blanks upon its first appearance, and the defect attended to at once, much less money will be spent in repairs than if the matter be allowed to progress from bad to worse and not remedied until it becomes absolutely necessary to attend to it.

The superintendent is held directly responsible by his employer for the results which he produces. The degree of success or failure of the company rests entirely upon his shoulders, and he should therefore be given the privilege to put into effect whatever methods he deems advisable. Under no circumstances should his methods be disputed or confidence lost in his ability until positive proof of the same is at hand. In the meanwhile perfect harmony should characterize all dealings between the superintendent and his employers, and they should endow him with power plenipotentiary so that his subordinates will regard him as the one man in authority whose orders are not to be questioned. If complaints occasionally arise or accidents sometimes occur, the superintendent should have the hearty cooperation of his employers in smoothing out matters to the satisfaction of the public who may have had to submit to more or less inconvenience. No matter how well regulated be the station or how systematic its operation, occasional accidents will occur, and complaints from an overexacting public will be entered regardless of the efficiency of the service. It is therefore necessary that due allowance be made for irregularities of this nature when they do occur.

If the efforts of the superintendent fail to produce the desired results after he has been in charge for a reasonable length of time, he should be informed of the fact, in a private conference, by his employers. Information regarding the nature of this meeting should be withheld from the rest of the force, for even if the superintendent is to be discharged he will presumably be given a month's notice, and during that time he should exercise the same authority over his subordinates as he did previous to the conference.

SOME REMARKS UPON CAUSES OF BREAKDOWN IN ELECTRIC MOTOR INSTALLATIONS.*

BY A. H. M.

That accidents will happen and repairs from time to time become necessary to all classes of machinery is beyond dispute, but as far as the direct current motor is concerned, the trouble might frequently be avoided by the exercise of a little extra foresight with regard to the details of the installation. How much depends upon mere details, both with reference to the construction of the motors themselves and also the accessories, will probably be made painfully manifest when the machinery has been running for a short period under working conditions. By the expiration of a few months an employe will certainly have found an opportunity of getting a spanner or other equally undesirable article firmly jammed between the armature and pole piece of the open type motor which has so far given no trouble, and this expensive mishap will bring out the advantages of the protected ventilated type with considerable distinctness.

Then, again, those shunt windings (the writer has seen many such) merely insulated from the pole-piece by a few turns of paper and cotton cloth will suddenly develop an earth to the framework, and as a result the field coils must be entirely removed. This points with no uncertain finger to the necessity of a bobbin of hard fiber or similar suitable material for winding the coils upon. With regard to these bobbins, it is highly important that the end disks and connecting sleeve shall be in one piece, or at any rate shall be so joined that oil or moisture cannot find an entrance, as damage to the coils will often make a start at this point if moisture finds its way in. The last few outside layers of wire should also be satur-

*From the "Electrical Engineer," London.

ated with a highly insulating and waterproof varnish, forming practically a damp-proof skin over the whole. The above remarks with regard to insulation will also apply in some cases to the armature, the writer being conversant with several machines in which the insulation between the armature disks and the winding is quite insufficient to stand the test of time, although a really fabulous voltage may have been employed in testing previous to leaving the maker's works.

Or, again, trouble may arise because for some reason the armature of motor No. 3 refuses to revolve, even when encouraged by the application of a current immensely in excess of the carrying capacity of the windings, and when by steadily reinforcing the conveniently handy fuses the attendant at last succeeds in burning out the armature, the machine will be overhauled and the alarming discovery made that the nut provided to hold the commutator in position has worked loose and jammed back against the framework. An additional thin lock nut or even sunk set screw would have saved all this damage. Many a disaster amongst electric motors has been caused by the accidental dragging out of the shunt lead from its terminal. This is one of the most inexcusable of accidents and is directly attributable to the use of ordinary set-screw terminals. Set screws have a habit of working loose in time, especially when subjected to the constant vibration attendant upon the running of an electric motor. Even when firmly screwed down the grip is of a poor mechanical character, and for this reason the shunt lead should not be less in section than $\frac{7}{20}$ S.W.G., and the end should be thoroughly soldered into a thimble and loop, and the loop fitted over an upright threaded terminal, and held firmly by means of a spring washer and a winged nut. It may be added that a large winged nut and a hard bronze spring washer fitted to an upright threaded brass stud form a most excellent terminal for the main current leads as well as the shunt.

The running parts of motors are often unduly strained, especially where a direct drive by toothed gearing is employed, by allowing too large a starting torque with the starting switch arm on the first contact. This is, of course, due to the fact that the total resistance of the rheostat is too low. Probably, in the majority of cases, the starting current required exceeds the full-load current by about 50 per cent., but that is no legitimate reason why such a rush of current should pass through the armature all at once. A properly designed rheostat should have its resistance so graduated that about half of full-load current will pass with the starting arm on the first contact, full-load current on the second, and then, providing that the motor has not started, the current should rise to about 50 per cent. excess on the third contact. Even when the motor does not start with the first two sections of resistance, cut-out work is being done, as the current passing through the armature is tending to move it, and the next rise of current will start the motor without undue shock or strain.

The original cost of an installation is often unduly increased by the employment of motors of the totally inclosed class, owing to the low efficiency of such machines from overheating. There are, of course, cases in which it is necessary to use the totally inclosed type, but the protected ventilated motor would often be equally as suitable for the work and far more economical. Improper connections between the starting switch and the motor are sometimes responsible for damage, especially if the shunt wiring is not properly connected. The writer has seen several instances in which the shunt lead is taken direct from the double-pole switch to the motor terminals. This is quite wrong, as upon opening the double-pole switch the shunt circuit is suddenly opened, and a great strain thrown upon the insulation. The lead for the shunt terminal of the motor should always be taken from the first contact of the armature starting resistance, and upon breaking circuit the shunt discharge will expend itself in discharging through the main resistance. The type of starting switch selected for use in the installation will exercise an immense influence upon the satisfactory, or otherwise, working of the plant.

Starting switches are generally described in makers' lists as a given horsepower and a given voltage. It would be far better if a further sub-division were made classing the switches for heavy and for light duty. A certain starting switch may satisfactorily start a motor of given horse-power and voltage, but may at the same time be utterly unsuitable for continuous and heavy starting work such as starting apparatus is called upon to perform in large engineering works. When the motor is to be frequently stopped and started, and the starting load uncertain, and likely to reach a large excess current, it is absolutely imperative that the carrying capacity of the resistance shall be ample to meet emergencies, otherwise continual expense and annoyance will follow. For the above heavy duty it is necessary to provide contacts of the renewable segment type, and the contact maker should be of ample area.

One other point, which cannot be too frequently driven home, is the absolute necessity of providing reliable fuses in each motor circuit. They are a perfect safeguard, and, where omitted, a heavy bill for repairs and stoppages will mount up swiftly and surely.

The extent to which electric driving has been adopted during the last five years is ample evidence in establishing its superiority over the older forms, and it would indeed be a pity to hinder its further rapid progress by lack of attention to small matters, which may amount to a great deal in the formation of the user's opinion of his installation at the end of year.

The Telegraphic Transmission of Handwriting and Pictures.

Prof. Cerebotani, of Munich, recently lectured at the Berlin Urania on the interesting telegraphic apparatus designed by himself. After continuously improving his invention for many years past, says the *Electrical Engineer*, London, Cerebotani finally tested the same on the telegraphic lines connecting Munich and Augsburg, Milan and Rome, Milan and Turin, and finally Munich and Berlin, the results being quite satisfactory. It is intended to apply the system to wireless transmission of pictures, etc., which would be particularly easy on account of the exceedingly small current intensities (about two milliamperes) sufficient to actuate the receiving apparatus.

The electromagnetic arrangements consist of four coils, comprising two windings each and crossing one another on a small board. According as the currents put into these coils are more or less strong and of the same or opposite directions, an enormous quantity and variety of currents may be generated in both directions, resulting in corresponding electromagnetic effects. The nearly unlimited number and variety of these current impulses is the most important feature of the apparatus, while the receiver shows a similar arrangement. In the case of the apparatus being used as a type-printing telegraph, the metallic types embedded in a non-conductive substance obviously play the most important part with the transmission.

The Cerebotani apparatus, is likely to assume considerable importance as a facsimile telegraph. In the latter case the sending apparatus contains a pen, carried over the paper by means of a system of co-ordinates, and to which corresponds a similar device in the receiving apparatus, which, however, is susceptible of being

modified or reduced. The system of coordinates is embodied by two bars crossing each other at right angles, and being provided each with a slit where the other is made to slide. By means of this device for guiding the pen the latter may obviously be conveyed to any point of the writing paper, producing at each point the current impulse corresponding to the same, and which will cause the pen placed in the receiving apparatus to record this point at the identical place in the receiver. Some practice, it is true, is required to handle the apparatus. A speed of 100 letters per minute seems to be quite practicable, and the apparatus may be used wherever a Morse apparatus is being employed. It may even be connected to a telephone, and used simultaneusly with the latter. The range of transmission seems to be practically unlimited. In the case, however, of any drawbacks being met with in this connection, relays would have to be resorted to.

ELECTRIC LIGHT CONVENTION.

Plans Nearly Completed for the Meeting to be Held in Boston.

Following is the programme of papers and reports to be presented at the 27th Convention of the National Electric Light Association, to be held in Boston May 24, 25, 26 and 27:

PAPERS.

"The Sale of Electrical Energy"—W. F. White.

"Economy Test of a 5,500 Horse-power, Three-Cylinder, Compound Engine and Generator"—J. D. Andrew and W. F. Wells.

"A One-Hundred-Mile Transmission Line"—Robert Howes.

"The Mechanical Stoker and the Human Operator"—Edwin Yawger.

"The Organization and Equipment of an Arc-Lamp Department"—Samuel G. Rhodes.

"Practical Notes on Steam Turbines"—Francis Hodgkinson.

"Electric Light and Power Plants in Connection with Ice Plants"—C. L. Wakefield.

"Single-Phase Power Motors for Electric Lighting Stations"—W. A. Layman.

"A Three-Wire, 500-Volt Lighting System"—Walter I. Barnes.

"Notes on the Internal-Combustion Engine as Applied to Central Station Service"—E. E. Arnold.

"A Proposed System of Standard Instruments for Operating Companies"—H. P. Davis.

"Remote Control of Electrical Apparatus"—William H. Cole.

In addition to these papers, which are already in print, are three or four others on timely subjects which have not yet gone to press, among them one by Dr. F. A. C. Perrine, on "Types of Large Water Power Installations."

REPORTS.

Report on Progress—T. Commerford Martin.

Report of Committee on District Heating—E. F. McCabe, chairman.

Report on Lost and Unaccounted-For Current—C. W. Humphrey.

Report on Purchased Electric Power in factories—W. H. Atkins, chairman.

Report on Office Methods and Accounting—Frank W. Frueauff.

Report on Advertising—LaRue Vredenburgh.

Report on Sign and Decorative Lighting—Arthur Williams.

Report on Analysis of Flue Gases—Henry L. Doherty, chairman.

Report on Standard Rules for Electrical Construction and Operation—Capt. William Brophy, chairman.

Report of Committee Appointed to Investigate the Steam Turbine—William C. L. Eglin, chairman.

Wrinkle Department—Edited by Chas. H. Williams.

Question Box—Edited by H. T. Hartman.

There are 100 or more "wrinkles" submitted. and the Question Box contains nearly 450 questions, nearly every one of which has been answered.

In addition to the papers above enumerated will be the paper an "Underground Construction," for which Past President Doherty will present a gold medal.

ENTERTAINMENT.

Mr. James L. Ayer is chairman, and will have a staff of 63 assistants.

The following programme will be carried out for the entertainment of the visitors.

On Tuesday afternoon the ladies in attendance will take carriages and drive through the Fenway and possibly to some points of interest about Boston.

On Tuesday evening there will be given at Hotel Vendome a lecture on "Historical and Electrical Boston."

On Wednesday morning the ladies will visit the shopping districts.

On Wednesday afternoon there will be a trip down the harbor, and on return a visit to the L street station of the Boston Edison Company.

Wednesday evening will be spent in Symphony Hall, attending a popular concert. All the space within the rail has been reserved for use of the guests and their friends.

On Thursday there will be provided for the ladies a trip in automobiles to Wayside Inn, Lexington and Concord.

On Friday the entire day will be devoted to personally conducted trips in and about Boston. The business sessions of the association will close on Thursday evening, leaving Friday to be devoted purely to entertainment in the manner above outlined. A general information bureau will be established at Hotel Vendome, in charge of Messrs. Vose and Peasley, and in addition to the usual duties that such a bureau is intended to have, during the week lists made of those desiring to take any particular trips to see any particular points on Friday, so that adequate arrangements may be made for properly personally conducting the visitors to such places as they desire to go.

The foregoing briefly outlines the general plan, more definite details of which will be incorporated in the programme, which will be printed in a short time in advance of the meeting.

Prof. Thurston's Successor.

At Ithaca, N.Y., on Saturday the Board of Trustees of Cornell University elected Prof. Albert W. Smith director of Sibley College of Mechanical Engineering, to succeed the late Robert H. Thurston.

St. Louis World's Fair Exhibits.

The Standard Underground Cable Company in conjunction with the McRoy Clay Works have a joint exhibit in Section 3, immediately adjoining the northwest entrance of the Electricity Building, at the World's Fair.

The exhibit shows a cross-section of an actual conduit, consisting of 72 ducts with a manhole at either end, one manhole being complete with a cover, the other being open. A trench 7 feet deep and 5 feet wide extends the entire length of this conduit, enabling close inspection of the method of laying conduits, including the wrapping, concrete base and top, and the general construction of the manholes, showing hangers, pipes to poles, etc.

At one end in the manhole is shown a capstan rigged up for drawing in cables and connected to a cable which is mounted on a reel at the other manhole; the cable being drawn through the ducts and part of the ducts being split so as to show the method of fastening cables to rope, etc.

From the manholes, cables go to distributing poles, showing the method of distribution to aerial cables for telephone, electric light and street railway work, with various terminals used to protect the ends of the cable in such work.

The McRoy Clay Works show piles of clay as it is dug from the ground and the various processes through which the ma-

terial goes to produce the finished duct.

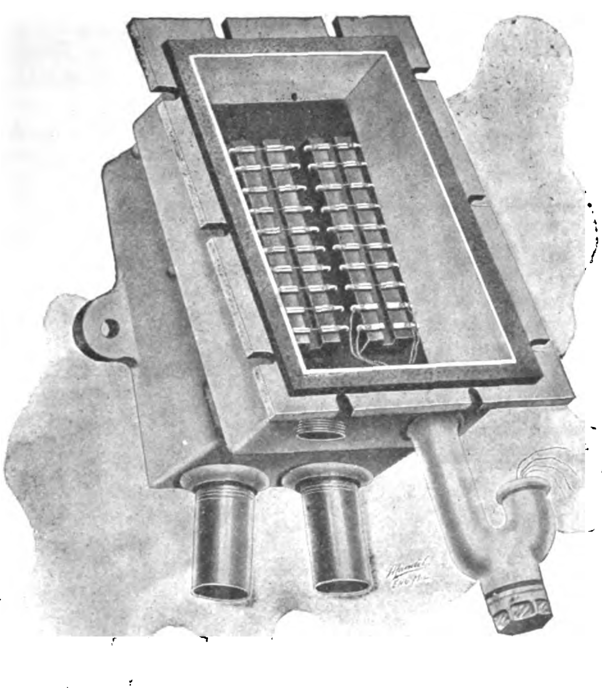
The Standard Underground Cable Company shows samples in handsome cases of all the various cables and appliances made by the company. An examination of this system will show, in every complete detail, the method of installing conduits and drawing cables into completed conduits.

The Andrae O. K. Distribution Box.

Time and practice have demonstrated that the underground electric system, with its clay conduits through which leaded electric cables run, is perfectly safe and economical and a necessity for quick transaction of business by telephone or for public security in connection with fire and police protection.

It is claimed that the Andrae O. K. Distribution Box allows you to add, subtract or change without disturbing the system.

The illustration herewith represents a



ANDRAE PATENTED JUNCTION BOX.

patented junction box. The box is of cast metal and the front side has a removable cover with brass bolts and screw connections, and is provided with a rubber gasket to keep out the moisture. The bottom of the box has two or more tapped openings for screw threaded brass nipples, engaged by the cables, and these brass nipples and cables are united by soldering joints.

Each box is provided with two goose necks which can be attached whenever necessary under the front of the box through insulation to scrape off. No taping and no soldering.

For further information write to Julius Andrea & Sons Co., 225 West Water street, Milwaukee, Wis.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 3, 1904

Electric Railways and Appliances.

758,757. Traction-Engine. William R. Jones, Kremlin, Okla. Filed Jan. 30, 1904.

758,785. Electric-Railway Trolley. David M. Shaler, Stryker, O. Filed Aug. 6, 1903.

758,922. Signaling on Electric-Traction Systems. Thos. H. Jones, Portsmouth, Eng. Filed July 7, 1902.

758,977. Guard-Covering for Third Rails of Electric Railways. John Kress, New Rochelle, N. Y. Filed Dec. 30, 1903.

759,060. Electric-Railway Switch-Point and Operating Means Therefor. Arthur J. Backer, Syracuse, N.Y. Filed July 8, 1903.

759,098. Safety Device for Electric Railways. George Gibbs, New York City. Filed Dec. 24, 1903.

Electric Lights and Appliances

758,644. Electric-Arc Lamp. Thomas Hamilton-Adams, London, Eng. Filed Aug. 29, 1903.

758,730. Electric Lamp. Alexander J. Wurts and Edward Bennett, Pittsburg, Pa., assignors to George Westinghouse, same place. Filed Jan. 10, 1901.

Electrical Machinery and Apparatus

758,610. Controller for Electric Motors. Thomas E. Barnum, Milwaukee, Wis., assignor to the Cutler-Hammer Manufacturing Company. Filed Feb. 7, 1902.

758,621. High-Tension Circuit-Breaker. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 13, 1902.

758,631. Collector-Rings and Brush-Holders. Karl F. Elers, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 26, 1903.

758,635. Direct-Current Generator. William H. Foot, Wilkinsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 16, 1903.

758,647-648-649. Electric Safety-Fuse or Cut-out. John A. Heany, York, Pa., assignor to the Teter-Heany Developing Company, Charleston, W. V. Filed Oct. 12, 13 and 14, 1903.

758,667-668. Single-Phase Alternating-Current Power System and Motor. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Dec. 26, 1901, Oct. 31, 1902. Renewed Sept. 24, 1903.

758,669. Brush-Holder for Electrical Machines. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 16, 1903.

758,683. System of Electrical Distribution. John S. Peck, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Aug 8, 1903.

758,702. System of Alternating-Current Distribution. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Filed Sept. 13, 1902.

758,726. Indicating or Recording Dynamometer. Edward Weston, Newark, and Adelbert O. Benecke, Vailsburg, N. J. Filed May 31, 1902.

758,756. Electrical Recording Device. James H. Johnson, Louisville, Ky. Filed July 15, 1903.

758,880. Machine for Testing Dynamos. James J. Wood, Fort Wayne, Ind. Filed Aug. 4, 1903.

758,938. Automatic Magnetic Circuit-Breaker. William M. Scott, Philadelphia, Pa., assignor to the Cutter Electrical & Manufacturing Company. Filed July 31, 1903.

759,004. Alternating-Current Motor. Burton McCollum, Lawrence, Kan. Filed April 4, 1903.

759,096. Frictional Electric Generator. Garabet Germakian, Paterson, N. J. Filed Aug. 22, 1903.

759,119-120. Electrical Conductor and Electric Inductive Conductor. Percy A. McGeorge, West Hoboken, N. J., assignor of one-half to William McGeorge Jr., Philadelphia, Pa. Filed Sept. 10, 1902, March 17, 1904.

759,122. Electric Dynamo. Roger M. Newbold, Birmingham, Ala. Filed Nov. 3, 1903.

759,150. Motor-Starter. William Baxter, Jr., Jersey City, N. J. Filed Feb. 9, 1904.

759,183. Method of Utilizing Single-Phase Alternating-Current Energy. Benjamin G. Lamme, Pittsburg, Pa., assignor to the Westinghouse Electric & Manufacturing Company. Original application filed Dec. 26, 1901. Divided and this application filed July 16, 1902.

Telephones and Telephone Apparatus.

758,623. Telephone System. William W. Dean, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed May 11, 1901. Renewed Sept. 24, 1903.

758,703. Apparatus for Telephone-Lines. Charles E. Scribner and James L. McQuarrie, Chicago, Ill., assignors to the Western Electric Company. Filed Aug. 2, 1900.

758,795. Telephone-Receiver. Ernest H. Strauss, Chicago, Ill. Filed May 25, 1902.

759,094. Telephone-Transmitter. James I. Gemmill, Cleveland, O. Filed Aug. 28, 1901.

759,095. Telephone-Receiver. James I. Gemmill, Cleveland, O. Filed Dec. 22, 1902.

Miscellaneous.

758,638. Lightning-Arrester. Louis R. Gaw, Asbury Park, N. J., assignor to Daniel Killion, Hoboken, N. J. Filed June 3, 1903.

758,650. Electrode for Vapor Electric Apparatus, Peter C. Hewitt, New York City, assignor to the Cooper-Hewitt Electric Company. Filed Jan. 13, 1904.

758,655. Magnetic Ore Separator. William L. Imlay, Philadelphia, Pa., assignor to Adolph Segal, same place. Filed Oct. 2, 1899.

758,692. Storage Battery. William J. Redmond, Cleveland, O. Filed Sept. 29, 1902.

758,701. Electric Burglar and Fire Alarm. Solomon Schwarzschild, Rochester, N. Y. Filed Feb. 24, 1902. Renewed Oct. 8, 1903.

758,724. Signaling System. Joseph Weatherby, Jr., New Cumberland, Pa., assignor to the Weatherby Electric & Manufacing Company, same place. Filed June 1, 1903.

758,73[illegible]. Printing-Telegraph. John C. Barclay, New York City. Filed July 24, 1903.

758,736. Automatic Fire and Burglar Alarm Telegraph. Robert G. Callum, Washington, D. C. Filed March 1, 1902.

758,819. Electric System for Indicating the Temperature of a Distant Point. Robert G. Callum, Washington, D. C. Filed Oct. 28, 1902.

758,842. Wireless Telegraphy. James F. King, Washington, D. C. Filed Dec. 17, 1902.

758,946. Electroheater. Edwin R. Waterman, San Francisco, Cal. Filed July 13, 1903.

759,007. Storage Battery. Job T. Niblett, Greenwich, Eng. Filed Feb. 5, 1903.

759,026. Electric Clock. Herbert Scott, Bradford, and Alfred Loebl, London, Eng. Filed June 10, 1903.

759,041. Magnetic-Speed Indicator. Simon B. Storer, Syracuse, N. Y. Filed April 16, 1903.

759,047. Electric Signal System. George L. Vannais, Hartford, Conn. Filed June 20, 1903.

759,058. Storage Battery. Vincent G. Apple, Dayton, O. Filed June 5, 1901.

759,065. Method of Accumulating and Using Electrical Energy. Anson G. Betts Troy, N. Y. Filed Aug. 17, 1903.

759,066. Electric Storage Battery. Anson G. Betts, Troy, N. Y. Filed Aug. 17, 1903.

759,148. Electric Attachment for Rocking-Chairs. Gaines M. Allen and Samuel M. Cawker, Denver, Col. Filed Nov. 3, 1903.

THE TELEPHONE WORLD.

Southern Bell Expelled from Tennessee.

Last week Chancellor Allison, of Nashville, ordered the Cumberland Telephone & Telegraph Company into the hands of a receiver, and moved that the corporation be ousted from the State. Later he amended his decree, stating that for satisfactory reasons he would decline to appoint the receiver. The telephone company entered an appeal to the next term of the Supreme Court. The appeal vacates the order of expulsion.

The company has an authorized capital of $20,000,000, and about $12,000,000 is outstanding. It controls the telphone situation in the South by reason of its relations to the Bell Telephone Company and has lines radiating into Southern Illinois and Indiana.

The Wolverine Telephone Company has been organized at Coldwater, Mich. The stockholders are all business men of Coldwater. This company and the Southern Michigan Telephone Company will exchange line service. The Southern Michigan Telephone Company is now operating over 500 'phones in Branch County. Coldwater is the largest city in Michigan not having an Independent exchange. That city and Hillsdale are the only two cities in Michigan not having Independent service. Lines are now being built into Hillsdale from all directions, and that city will soon have an Independent exchange.

The Plymouth, Mich., Telephone Company will soon begin the construction of a toll line to Livonia Center, with a pay station at that point, connecting on the way with farm residences. A line is also to be built to Canton. The advantage of these rural lines to Plymouth is very manifest as it brings the farmers in direct touch with the village and helps to build up the Plymouth business.

The Hutchison Wireless Telephone Concession Company of St. Louis, Mo., has been formed to operate a system of wireless telephones on a capital stock of $3.000. Among the men interested are M. R. Hutchinson, New Rochelle; Hallon C. Spaulding, Boston; Edward C. Husted, Joseph A. Wright and L. Z. Harrison, of St. Louis.

The Snyder County Rural Telephone Company was lately organized in Middleburg, Pa., by electing G. Alfred Schock, president, and J. M. Baker, of Beaver Springs, secretary. The company is organized to take the place of the United Telegraph & Telephone Company.

Chester, N. Y., is to have a mutual telephone apparatus of its own. At a recent meeting of citizens the matter was discussed, and resulted in a vote to make application for a charter with a capital of $2,000.

The Lewiston-Auburn, Me., Telephone Company is laying a conduit in which four cables can be placed and 800 persons accommodated on these wires. The automatic telephone system will be used.

The recently organized Independent Telephone Company at Wilkes-Barre, Pa., has C. H. Randall as president.

Bell Company Cannot Enter Van Wert, O

The Central Union Telephone Company tried to secure a foothold in Van Wert to operate an exchange by an application through the probate court, declaring that it had exhausted all means to secure a franchise through council. The city's attorneys filed a demurrer stating that the plaintiff was not entitled to the relief asked because it was a foreign corporation, and Judge Sweet, in a comprehensive opinion, sustained the demurrer. As the Central Union has made application in various probate courts of the State for franchises the decision of Judge Sweet may have a far-reaching effect.

Sanitary Telephone Mouthpieces in Germany.

A special mouthpiece for the public telephones has been introduced in Germany with the object of avoiding the spread of diseases carried by the condensed moisture of the breath. A pad of a large number of disks of paper, with a hole in the middle, is inserted in the mouthpiece, and the upper disk of paper is torn off after every conversation.

Telephones have been installed by the Louisville, Ky., and Southern Indiana Traction Company at all of its stations and sidings between New Albany and Jeffersonville. This will greatly facilitate the movement of the interurban cars and will put the men operating them in touch at all times with the office in New Albany.

The Commercial Union Telephone Company of Troy, N. Y., has filed with the Secretary of State a certificate of an increase of its capital stock from $10,000 to $800,000. The stock is to consist of $300,000 six per cent. preferred and $500,000 common stock. The company also filed a certificate increasing the number of directors from nine to fifteen.

One of the new enterprises of Eldridge, Ia., is the Eldridge Mutual Telephone Company, which was organized in 1903, with an authorized capital of $10,000. It has 150 subscribers, and its lines extend into all the immediate surrounding territory. James H. Wiese is president.

The question of establishing a telephone exchange is causing much interest in Rockport, Mass., and it is expected that some arrangement will be made whereby the telephone will be more generally used there.

The manager of the Home Telephone Company of Ft. Wayne, Ind., states that the company, is installing new telephones at the rate of 100 a month.

At the annual meeting of the stockholders of the International Bell Telephone Company held last week the retiring board of directors was re-elected.

The Independent telephone system at Cape Vincent, N. Y., has been purchased by John H. Grapotte.

An Independent telephone exchange will be installed and operated at Keensburg, Ill, by Elisha Rotrammel.

Telephone Company to Change Name.

The Golden Rod Telephone Company that located in Osceola, Neb., a couple of years ago, reducing the rates a third from what had always been paid for 'phones in that town and county, has sold out to a party from Ida Grove, Ia. The present county treasurer of Ida County, Ia., I. M. Shearer, being the president of the corporation, proposes to change the name to the Polk County Telephone Company..

After considerable agitation on the part of the members of the Business Men's Association, the New York & New Jersey Telephone Company has consented to grant relief from the excessive tariff which has existed previously. Subscribers in Flushing, L. I., have heretofore paid $48 per year, and were entitled to 500 local calls, which include Flushing, Whitestone and College Point. The concession that the company has just made will permit Flushing subscribers to have an unlimited number of local calls for $48 per year. The company has also promised to consider the matter of reducing the toll charges to Jamaica, Brooklyn, Long Island City and Manhattan.

The Olathe, Kan., Citizens' Telephone Company has been sold to Oscar Ayers, of Gardner, Kan, for $20,000. Mr. Ayers is the owner of the Gardner Telephone Company, but will remove to Olathe and manage his new company, of which he is president and general manager. F. R. Ogg has been elected vice-president of the new company; M. G. Miller, treasurer, and H. C. Livermore, one of the directors. The sale included all of the Citizens' Company's lines throughout Johnson County.

The Ravena & Medway Telephone Company was lately incorporated in this State with a capital of $5,000. The line will extend from Ravena to Medway and the town of New Baltimore. The directors are William C. Harden and Ernest Bilz, of Stanton Hill; Harry Thorne, New Baltimore; Clifton Bedell, Aquetuck; E. L. Haight, Arthur Hartt, Frederick C. Bush and Clarence E. Whitney, of Ravena. Harrie McK. Curtis, Coxsackie.

Telephones are being installed in Tewksbury, Mass., and when completed there will be quite a system and one which will prove of much convenience. The only limit on the system is that subscribers in the farmers' system have to pay toll charges when using the line outside of their own town, and the same in regard to persons calling them. Beyond that the service is as available as the general system.

Telephone Incorporations.

The Evansville Telephone Company, Evansville, Ill. Capital stock, $2,500. Incorporators: William Wolff, John V. Tummel and William R. Mathews.

The Tenney Telephone Company, Alma, Wis. Capital stock, $2,000. Incorporators: Jacob S. Tenney, John T. Tenney, Jacob Accola and Valentine Thoeny.

The People's Telephone Company, Mercer, Me. Capital stock. $2,700. Incorporators: C. K. Allen and N. E. True.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Alton, Ia.—It is reported that an electric light plant will be erected by the town. The plant will be equipped with modern appliances and machinery.

Alturas, Cal.—The Alturas Electric Light & Power Company has been incorporated by D. E. Mulkey, I. W. Gibnins and others. Its capital stock is $20,000.

Aurora, Ill.—Commencing with June 1 there will be but one electric lighting and power plant here, that of the Fox River Light, Heat & Power Company.

Burlington, Ia.—Messrs. Sweet and Caster will be in charge of the installation of the new electric light plant here.

Clinton, S. C.—The city council is considering a proposition made by some Washington capitalists to put in an electric light and waterworks system.

Depere, Wis.—The Electric Light & Power Company will spend about $1,500 in improving its system.

Elkton, Ky.—The officials have made a five-year contract for lighting the town by electricity with E. L. Peck, who conducts the plant at Guthrie.

Goffstown, N. H.—An electric light plant is being contemplated here. The committee appointed comprises J. G. Dodge, F. A. Parker and others.

Jasper, Ind.—The town board has purchased the electric light plant here of the Jasper Electric Light Company.

Madera, Cal.—The Madera Electric Light Company's plant is to be rebuilt and improved. F. W. Krogh is president. A 150 hp. boiler and a triple expansion engine of 150 hp. will be installed and the line will be extended to parts of the town not heretofore lighted.

Napoleon, O.—Proposals will be received by the village clerk for $25,000 4½ per cent. coupon bonds for electric light improvements.

New Castle, Pa.—Business men here and at New Wilmington and at Pulaski are considering a trolley line to connect the three places. A. B. Getty, J. M. Houston and R. J. Totton are among those interested.

New Concord, O.—J. K. Mercer of Woodsfield, O., has secured the contract for installing an electric light plant for the New Concord Electric Light & Power Company. This company wants one 100 hp. steam engine, and boiler to suit a 75 kw. A. C. dynamo. Dealers having second hand machinery for sale may address the Zogg Electric Company in care of N. A. Geyer, of this place.

New Haven, Ind.—J. M. Jackson, town clerk, states that bids were received for constructing an electric light plant, and all were rejected. Bids may be readvertised about May 15.

Paris, Ill.—George E. Levings and John C. Risser, receivers for the Paris Gas Light & Coke Company, have been unable to dispose of the plant at a private sale, and will publicly auction the gas plant, electric light and heating plant May 21.

Pittsfield, Me.—A recent fire destroyed the large plant of the Pittsfield Electric Light & Power Company, entailing a loss of $50,000.

Salt Lake City, Utah.—The owners of the D. F. Walker Block may install their own electric light, power and heating plant. The estimated cost is about $20,000.

Sayre, Pa.—The council has decided to install five 1,200 cp. electric lights in the business portion of the town, taking the place of gas lights.

Shediac, N. B.—The Shediac Electric Light & Power Company has been granted papers of incorporation by the Legislature.

St. Francis, Wis.—The board of directors of the St. Amelianus Orphan Asylum has voted to install a new electric light plant, including generating outfit and probably some changes in the heating system. George W. Collies, of Milwaukee, is engineer.

Sylacauga, Ala.—At a recent meeting of the council a $20,000, bond issue was authorized, the proceeds of which will be spent in the erection of a water and electric light plant.

Wauwatosa, Wis.—A municipal electric light plant is under consideration. The Advancement Association is interested.

Wichita, Kan.—An electric light and waterworks franchise was lately granted to J. C. Borntregor.

STREET RAILWAYS.

Auburn, Me.—Edgar S. Hill, of Boston, who was recently here on business in connection with the proposed Auburn-Turner Electric Railroad, made satisfactory arrangements with M. J. Googin, of Lewiston, to solicit the preferred stock.

Bainbridge, Ky.—The Chillicothe, Bainbridge & Aberdeen Traction Company is the name of a new company to build a line from Chillicothe via this place to Aberdeen.

Cedarville, O.—The council has granted a franchise to the Springfield & Washington C. H. Traction Company, to build and operate an electric line on the streets of this city.

Chariton, Ia.—Messrs. E. A. Ferrin, of Marshalltown, and F. B. Ufer, of Toledo, are the promoters of the Chariton-Knoxville, Electric Railroad.

Covington, Ind.—James Copeland, C. L. Woody and E. Heath are interested in the proposed electric railroad from here to Rockville.

Danboro, Pa.—A movement is on foot to build an electric railway from Point Pleasant to this place. It is stated that the Philadelphia & Easton will build the road.

Dowagiac, Mich.—H. C. Mason, manager of the McMicheal Electric Railroad interest, says that a franchise is now being secured from Silver Creek Township.

Hillsdale, Ind.—J. H. Roberts, of Grand Rapids, is interested in a new electric line for this city.

Indianapolis, Ind.—The board of county commissioners has granted a franchise to J. P. McGratz, of Hartford City, for an electric road through Delaware Co.—The Chicago & Northern Indiana Railway Company, which proposes to build an electric line from here to Chicago, has filed articles of incorporation in this State.

La Grange, Ind.—The right of way has been secured by the La Grange-Elkhart Electric Railroad Company, of which H. E. Bucklen is president, to build a line between Middlebury and this place.

Leadville, Col.—The announcement was lately made that a first-class electrical system is to be installed in the Yak tunnel. Three miles of underground trolley is one of the features of the proposition. The big electrical plant will be located at the mouth of the Yak tunnel and the trolley wires will penetrate all the crosscuts connected with the property, as well as the main bore.

Mansfield, O.—The Mansfield & Eastern Traction Company will soon commence work on its new traction line.

Marshalltown, Ia.—The promoters of the Marshalltown Street & Interurban Railway Company are planning to run an electric railway through Butler and Grundy Counties.

Mt. Vernon, O.—Fred Jones, of this place, is endeavoring to promote an electric line from Barberton to Doyleston.

Port Huron, Mich.—The City Electric Railway Company has under way plans to improve its lines here.

Schenectady, N. Y.—This city will offer for sale at public auction on May 17 a franchise for the building, construction, and maintenance of an electric railway. J. C. McDonald is clerk of the board of contract and supply.

Taylorville, Ill.—The American Central Traction Company has been organized to build an interurban electric line from here to Shelbyville.

Westfield, N. Y.—A trolley railway that will connect this place with Barcelona, an abandoned port of entry on Lake Erie, a few miles from here, is talked of. Rights of way are being secured. The terminus will probably be used as an excursion point.

POWER PLANTS.

Ceresco, Mich.—It is stated that W. A. Foote, president of the Kalamazoo Valley Electric Company is interested in a $20,000 power plant to be erected here by that company.

Gouverneur, N. Y.—Eli Pettis has sold the old saw mill property to B. G. Parker, of this place, who has purchased the same with a view of developing electric power.

BIDS WANTED.

New Harmony, Ind.—Bids are asked until May 16 for all machinery, apparatus, materials and supplies of every kind for an electric light plant for this city, f. o. b., care New Harmony, or delivered on the ground at site of plant, and for any and all parts of the work. George Cadogan Morgan, engineer, 808 Royal Insurance Building, Chicago; John H. Chaffin, president board of trustees; C. H. Wheatcraft, clerk.

New Haven, Ind.—Bids are asked until May 24 for constructing an electric light plant. Address John M. Jackson, town clerk.

New York City.—The Navy Department, through the bureau of supplies and accounts, is inviting sealed proposals until May 17, for furnishing the New York Navy Yard with 47,000 feet lighting wire, single conductor; two portable testing sets, two ohm-meters, four testing generators, three tachometers, a quantity of platinum, compressed mica plates, etc. Specifications and full information will be furnished intending bidders upon application to the bureau or to the navy pay office in New York.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, $13\frac{1}{8}$@$13\frac{1}{4}$c.; Lake $13\frac{3}{8}$@$13\frac{5}{8}$c.; casting, $12\frac{7}{8}$@$13\frac{1}{8}$c.

The Boston & Worcester Street Railway Company will declare a dividend on its preferred stock in July at the rate of 4 per cent. a year.

A dividend of 2 per cent. has been declared on the Indianapolis Street Railway stock, payable July 1 to stock as registered June 25. The books close on the latter date.

Owing to delay in receiving some of the briefs it is said the decision in the 99-year traction franchise case in Chicago will be delayed about ten days, and the opinion will be given by Judge Grosscup and Jenkins about May 25.

President McCall of the Philadelphia Electric Company says there is no truth in the report that there are any plans being contemplated for the acquisition of the Philadelphia Electric Company by the United Gas Improvement Company.

The Toledo Electric Storage Battery Company, capitalized at $100,000, has been reorganized with Joe Grasser as president. The inventor, George J. Miller, and Messrs. Tyler Greene, Louis Alexander and Mr. Dick remain with the company.

The Mutual Electric Light Company of San Francisco, of which D. O. Mills is a large stockholder, proposes to issue $400,000 five per cent. bonds for extensions. This company is the only competitor of the San Francisco Gas & Electric Light Company.

Judge Colt, in the United States Circuit Court in Boston on Monday, appointed John L. Hall of Boston, John P. Burnett of Southboro, and George E. Newhall of Providence receivers for the Lowell & Boston and the Concord & Boston Street Railway Companies.

The Central Trust Company, as trustee for the bondholders of the Brush Electric Illuminating Company, has brought suit to foreclose the mortgage on the property, alleging that the interest due in January last has not been paid. The bonds outstanding amount to $275,000.

The Peekskill Lighting and Railroad Company has been given permission by the New York State Railroad Commission to increase its capital stock from $500,000 to $650,000, and the Auburn and Syracuse Railroad to increase its capital stock from $1,300,000 to $1,500,000.

The Light, Fuel & Power Company of West Virginia, the stock of which broke from $46\frac{1}{2}$ to $19\frac{1}{2}$ on the sale of 200 shares on the curb in New York Friday morning, and was afterward bid up to 48 by brokers said to represent the company, was formed in 1902 with a capital of $2,500,000.

The report of the Albany (N. Y.) Home Telephone Company, submitted at the annual meeting of the shareholders last week, showed that the company's earnings for the first fifteen months of operation had been 9 per cent. on the stock, after providing for all expenditures for operation and maintenance, and for interest on the 6 per cent bonds.

It is understood that the Metropolitan Street Railway Company of New York is only $125,000 behind last year in its gross receipts to date. It is figured by directors of the Metropolitan Securities Company that the Metropolitan Street Railway at the present time is running within 1 per cent. of its guaranteed 7 per cent. dividend, and this deficit would be quickly made good if the system of collecting fares could be made as efficient on the surface lines as it is on the elevated lines.

ELECTRICITY.

VOL. XXVI. NEW YORK, MAY 18, 1904. NO. 20.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries.......................3.00
Single Copies.......................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

Rapid Transit Talk.

The Rapid Transit Commissioners are considering a proposition of the moving platform syndicate—which has been endeavoring to get permission to do something in this city for so long—to build a subway through 34th street and install in it its moving platform system.

In the application for permission to construct the subway it was pointed out that arrangements had been made for transferring passengers to the elevated and subway lines and that when the Pennsylvania Railroad tunnel and the Post Office, just west of Herald Square, were completed present conditions would be unbearable. This is not to be denied, as the Pennsylvania Railroad Company alone will land passengers at the rate of 600 persons per minute at certain portions of the day.

As a solution of the congestion problem a representative of the moving platform scheme is reported as saying:

"We propose that the subway in 34th street be extended west to 9th avenue and east to 2d avenue, and that it be equipped with the moving platforms or continuous train. In other words, we propose to establish under this important street what may be termed a moving terminal for the continuous collection and distribution of passengers from and to all the intersecting north and south lines.

"For a single fare of five cents we will transport passengers, or cause them to be transported, from any point on the moving platform route to any point in Manhattan or Brooklyn reached by the Interborough Rapid Transit Company, whether by its elevated or subway lines.

"We will also carry over our route without additional fare passengers in transit from any one to any other of the Interborough Company's lines, provided that the journey of such passengers shall be continued in the original direction."

The Borough of Manhattan is of a peculiar shape and is ill adapted to the requirements of a great city, except from the shipping standpoint. There is bound to be more or less congestion of traffic, but it can be minimized by suitable rapid transit subways, equipped possibly with moving platforms, if steps are taken to have them built in time. The underground road should have been built and in operation ten years ago, and it is to be hoped that other subways will be built at once where they are needed and not be begun when they should be finished.

* * *

Electric Motors vs. Shafting.

Considerable has appeared from time to time in technical publications discussing the advantages and disadvantages of electrical driving for engineering establishments. At a recent meeting of the Manchester Association of Engineers in England Mr. B. Longbottom presented a paper bearing on the subject. In it among other things the author stated that in the past there has been great diversity of opinion as to whether each machine in a work should be driven by a motor, or a number of smaller machines should be grouped together and driven from a short line shaft by one motor.

It was, however, now generally recognized that where machines were in constant use, provided they were below a given horse power—say, 5 horse power—grouping was the most desirable. The greatest care, however, must be taken that too many machines were not driven from one motor, or that they were not spread over too wide an area, as that would entail additional shafting. But if a proper system of motor units were employed—and this was the first thing that

ought to be settled in planning the electrical driving of a works—there would be no difficulty in obtaining a high efficiency, as it was only necessary to sub-divide the machines into the most efficient groups to suit the units.

In the average engineering works 5 brake horse power could be taken as the smallest unit to be used, except in special cases of isolated machines, or machines used for intermittent working. This motor had an efficiency of 82 per cent. at three-quarter load, and could, therefore, be looked upon as an efficient power unit.

In the majority of cases the other useful power units could be taken as 7½, 10 and 15 brake horse power, and only in works where very heavy materials were handled would it be found necessary to have larger units, except, of course, for individual machine driving.

It was not only shown that the efficiency of electrical compared favorably with that of mechanical distribution; there were other advantages that could not be overlooked. In these days of specialization it was of the greatest importance that machinery and departments should be arranged with a view to economical and increased output, and it was now possible for the works organizer to achieve that result without taking into account how the power had to be delivered to the machines. It was no longer necessary to arrange the machines in parallel lines down the works so that it could be driven from line shafts supported from the main girders, as was the case with the best arranged mechanical distributions; but under the same roof he could have as many sections of departments as he wished, each entirely self-contained.

It was quite probable that in attaining that result some sections would not be driven as efficiently as might otherwise have been possible; but provided the production was increased by the arrangement with the same outlay in labor it justified itself, and the saving of power, in such an instance, was of secondary consideration. Another advantage was that as they had not to contend with the weight and strain of heavy shafting on the girders, lighter structures could be used, resulting in a material reduction in the cost of the building, thus further defraying the outlay of the electrical plant. Then the advent of portable machine tools and other labor-saving devices had been rendered more possible by the electric motor, and the economies to be obtained by these methods of manufacture were daily becoming more apparent.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Governer Odell vetoed the Niagara Power bill. He declared that the measure was universally disapproved in the State and that he received protests from all over the Union.

Prof. Reginald A. Fessenden has placed a bid with the Russian Imperial Government, on behalf of the National Signaling Company, for the construction of two wireless telegraph stations at Port Arthur and Vladivostock.

The general meeting of the American Institute of Electrical Engineers will be held at the St. Louis Exposition during the week ending September 17, at which no unsolicited Institute papers will be presented or discussed.

About 70 per cent. of the stock of the General Electric Company was unanimously voted last week at the special meeting increasing the capital stock of the company by $3,325,500. After the special meeting the annual meeting was held and directors were re-elected without change.

The number of incandescent lamps to every 1,000 inhabitants is greater in Boston than in any other city in the world.

An English exchange states that a mechanical genius has invented an automatic magnet safety-lock for the doors of railway trains. When the train starts all the "carriage doors" lock automatically and cannot again be opened till the train comes to a standstill, when they unlock automatically. The inventor will not get rich out of royalties in this country.

According to a recent dispatch from Washington, President Roosevelt overruled a decision of Patent Commissioner Allen in a case in which Thomas A. Edison is interested, and directed that a hearing be given to Mr. Edison, which had been denied. It appears that Mr. Edison applied for a patent in connection with his storage battery, and that another inventor working along the same lines, it is alleged, was permitted to withdraw his application and insert it in the substance of Mr. Edison's claims. Mr. Edison protested and asked for a hearing, which the Commissioner refused to grant. President Roosevelt was appealed to and granted the request, but Mr. Allen will have an assistant attend to the matter.

According to an English contemporary a Mr. John Gell, of the New Zealand Postal Department, has invented a new telegraph tape perforator. It appears that the instrument, which is for use in conjunction with Wheatstone senders, is in the form of a typewriter, and that the depression of keys corresponding to the required letters automatically effects the correct perforation and spacing of the tape. It is asserted that the saving in time which may be effected by the use of the new machine will be very considerable, a speed of 72 words per minute having been attained. The instrument may be worked by compressed air or electricity.

President Edgar, of the National Electric Light Association has completed final arrangements for the convention to be held in Boston May 24–27. He says that 25 papers and reports have been printed, and that copies will be distributed to those members who have announced their intention of attending the meeting, reaching them before they leave home, and thus enabling them to prepare themselves to discuss the papers intelligently.

There is renewed talk of a combine among the Independent telephone companies from the Atlantic seaboard to Kansas City. Officials of the Independent companies from Baltimore, Philadelphia and Pittsburg will within the next few weeks inspect systems in the West. Backers of the Pittsburg & Allegheny Company and other Western Independent lines, and President Mack, of the Keystone Company, of Philadelphia, and George R. Webb, president of the Maryland Telephone Company of Baltimore, are now in St. Louis to consider the matter. Former Senator William Flinn, of Philadelphia, is said to be at the head of the consolidation movement.

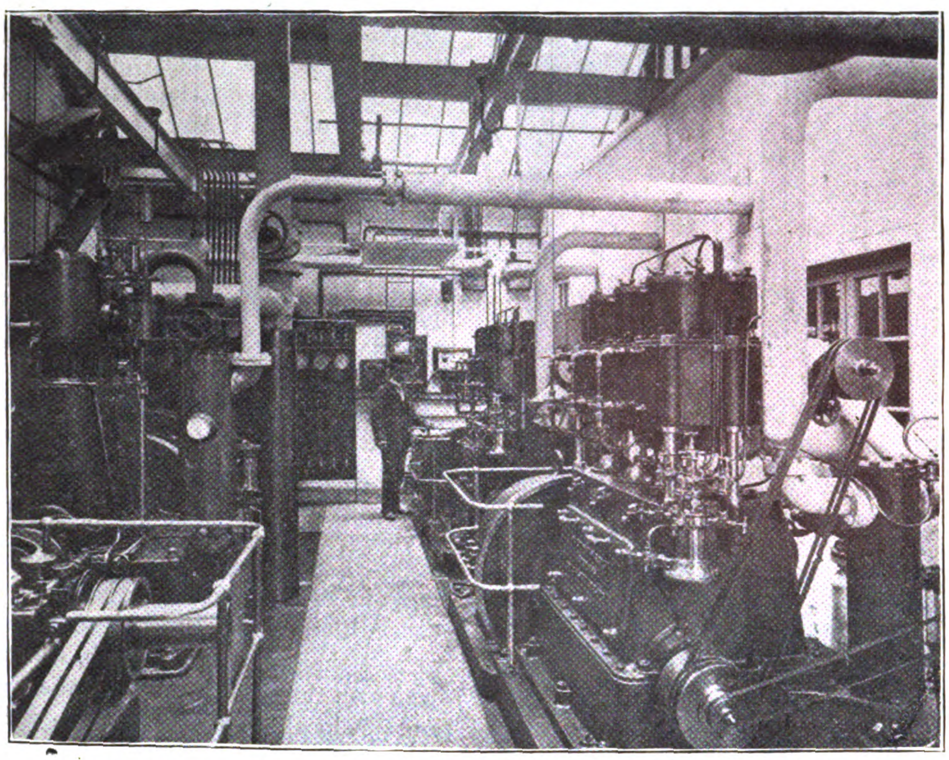
A supplemental report to be issued by the New Jersey State Board of Assessors shows that there are 70 trolley lines in New Jersey, with a total mileage of 980, and the estimated cost of equipment and roads is $160,344,176.31.

A Reuter telegram from St. Petersburg, published in several English newspapers, states that the Japanese, knowing that the Russians have been intercepting wireless messages, tried a clever ruse to deceive and harass the Russians. For several nights in succession, says the *Electrician*, London, they sent messages purporting to come from the Japanese Admiral ordering preparations to be made for landing, for sending fireships into the harbor, for attacking with submarines, and so forth.

A MODERN ENGLISH ELECTRICALLY OPERATED PIANO FACTORY.

BY FRANK C. PERKINS.

One of the largest grand piano-forte factories in the world has recently been completed in England near Old Ford Station and Victoria Park, and it is thoroughly equipped with electric power transmission and lighted throughout by incandescent electric lights. The accompanying illustrations show the power house installation as well as some of the numerous applications of electric power for driving the various cranes, elevators and shop machinery.



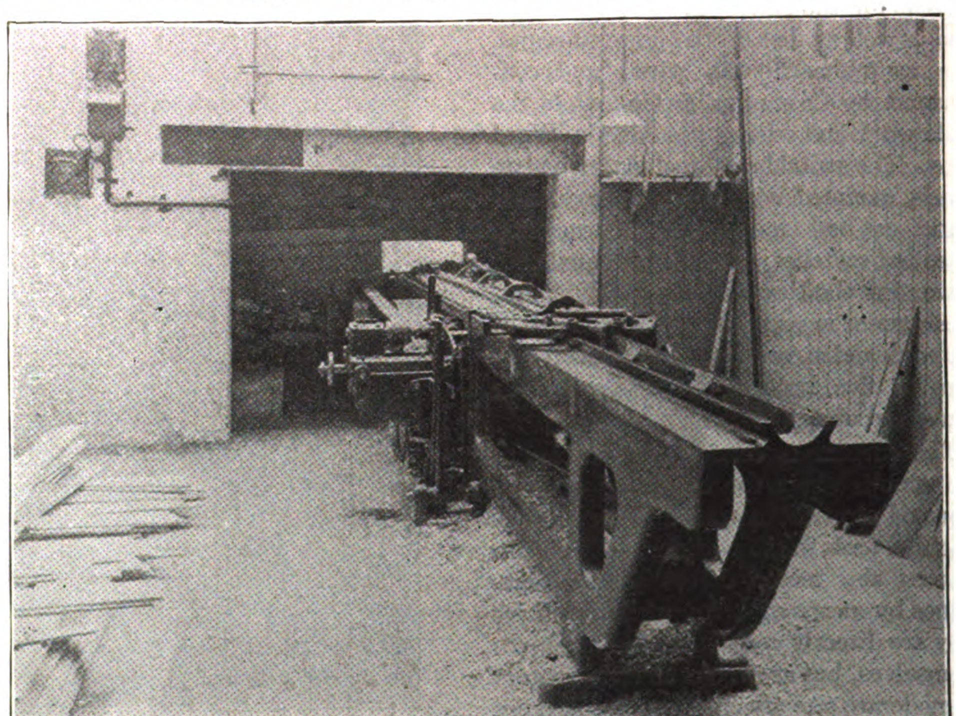
Engine Room in Electrically Operated Piano Factory.

The electric power transmission at the new works of Messrs. John Broadwood & Sons, Ltd., include machines directly driven by individual electric motors, also a combination system of driving the various machines, partly by high speed shafting and partly in groups. An electric railway has also been provided for transporting materials about the works and yards, and three floors are arranged with tramways and overhead traveler rails and appliances for the economical handling of the work, which lead to and from the four $1\frac{1}{2}$ ton elevators operated by 12 hp. electric motors.

An automobile electric crane is used in the yards for handling timber. This traveling jib crane is operated upon the electric railway about the new factory for placing the material in piles on one side of the track or transferring it to the trucks which are used for transporting the same to the ruff mill. This crane has a capacity of two tons, lifting this load at the rate of 50 feet per minute, while the speed when traveling is 220 feet per minute. It has a jib of 14 feet radius and timber may be stacked by it to a height of 12 feet from the ground. It is operated by a 15 hp. motor which runs at a speed of 500 revolutions per minute. It is provided with double friction clutches fitted on the main shaft and is arranged to revolve completely about in either direction. The crane revolves on four rollers and the traveling motion is transmitted by a vertical shaft from the main shaft, the vertical shaft passing through a hole bored in the center pin. The vertical shaft is connected to both of the axles by means of steel beveled gearings under the truck. For lowering a load a foot brake is provided, and while the load is being lifted a brake is arranged to hold it automatically if the current is broken, it being magnetically released when the current is flowing.

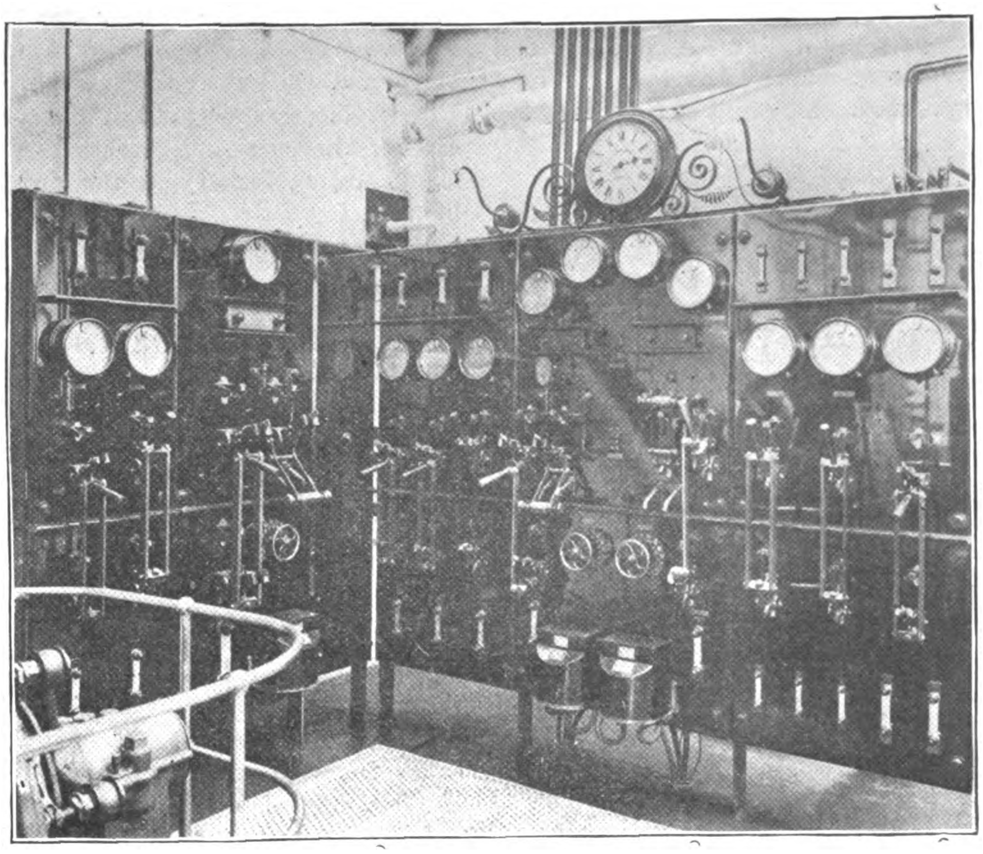
Before mentioning the other electrically operated machines at the works it may be of interest to consider the electrical equipment at the power plant. The boiler plant includes a 100 hp. Babcock & Wilcox boiler, which is fired by waste wood from the shop as well as by the saw-dust and shavings from the wood-working machinery conveyed to it by a Sturdevant pneumatic conveyor equipment. In addition to this boiler there are three locomotive boilers of 320 hp. capacity. The boilers operate at a pressure of 120 pounds per square inch and are supplied with feed water from which impurities have been removed by a Boby-Chevalet detartarizer.

The engine room is equipped with four engines, one of which is employed for driving the shafting of the wood-working shop and metal shop directly by belt transmission, while the other three engines are direct connected to compound direct current dynamos of the Crompton type, supplying current for operating all the other machinery at the works. Two of the engines are of the Peache high speed type, operating at 500 revolutions per minute. These engines are coupled to 40 kw. dynamos which are capable of heavy over-load.



Direct Driven Jointer in Electrically Operated Piano Factory.

The third engine is of the Belliss & Morcom high speed type running at 450 revolutions per minute. It is directly coupled to an 80 kw. electric generator and is capable of taking care of the heavy fluctuations in load successfully, and operates extremely well in parallel with either or both of the 40 kw. outfit. These engines and electrical generators supply the current for the entire incandescent lamp load as well as that of the power circuits. The switchboard was wired and constructed by Crompton & Co., while the cable work and wiring was done by Ward Bros. The switchboard includes five slate panels, mounted with the necessary automatic cut-out measuring instruments, fuses and switches, as well as an equalizing power for the three compound dynamos. The current is generated at a pressure of 230 volts and is conducted by common busbars to five lighting circuits and three power circuits.



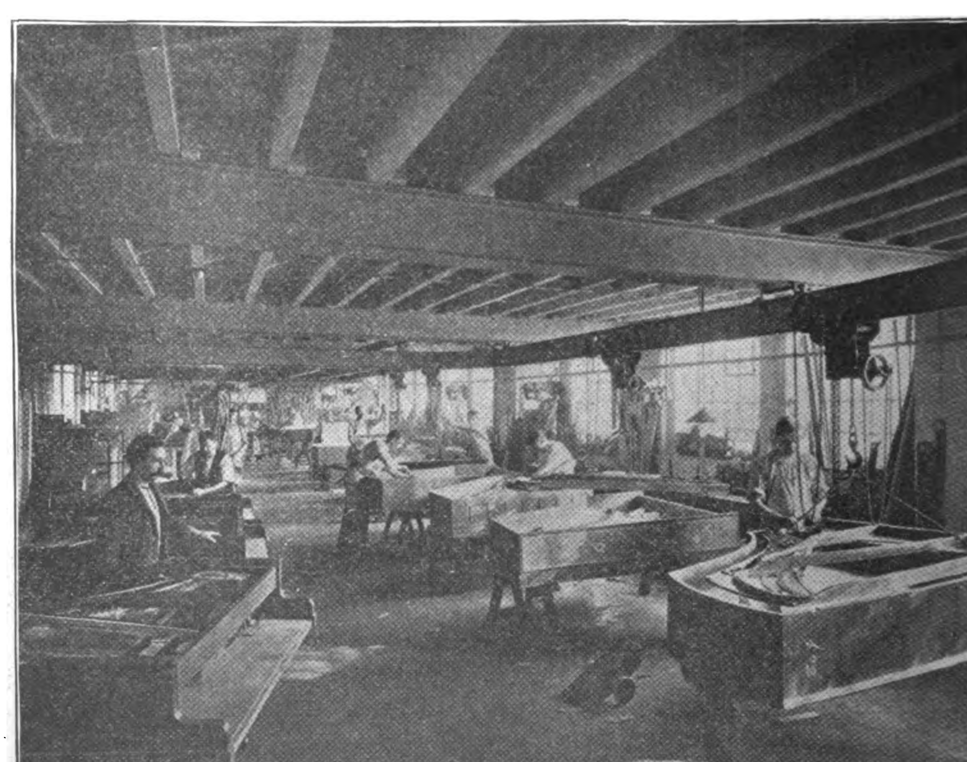
Switchboard in Electrically Operated Piano Factory.

The current is connected by cables to the various shops for operating about a score of electric motors driving various machine tools in the works. In some instances the motor drives separate machines by means of belts, while in others they are directly coupled to the machines themselves, but as a rule electric motors of moderate size are employed for driving groups of machines by light high speed shafting. As an instance of the latter method a 26 hp. motor is mounted on the floor of the rough saw-mill and is used to drive half of the saws in the mill, another 20 hp. motor being utilized for driving the remaining half; the motors are compound wound and thus give a very heavy torque under full load or overload.

To facilitate the removal of the sawdust and shavings every floor is provided with communication with a large shoot, from which the material is carried from the boiler house by a system of pneumatic conveyor, the fans providing the air exhaust and blast at a pressure of 1,000,000 cubic feet per hour, requiring electric motors of 36 hp. capacity; 7 hp. electric motors are mounted on shelves and drive the fans which supply the air exhaust to carry away the saw-dust from the saw benches. As an example of the electrically-driven machine it may be well to mention the new glue-jointing machine, which is directly coupled to an electric motor operating this machine exclusively.

Three of the electric elevators in this plant are of the Pickering type, the remaining two being installed by J. G. Childs & Co. The three-ton electric elevators have two ropes at each corner, which pass around pulleys at the top of the elevator shaft, and the 12 hp. electric motor drives the two shafts by two worm gearings, the thrusts of the latter being balanced.

A system of 20 electric clocks has been installed by the Synchronome Company, insuring uniform time throughout the factory. These clocks are driven by electric impulses sent over the circuits by a single master clock. As each workman enters or leaves the works he moves the arm of the recorder opposite to his number and then presses the knob, which indicates on the sheet the time of the operation. A local telephone exchange with 25 stations has also been provided.



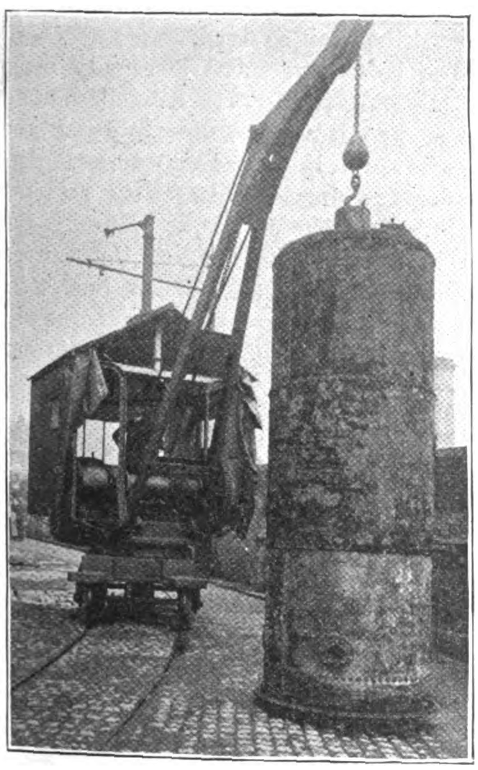
Grand Bellying and Marking Off (Overhead Runway) in Electrically Operated Piano Factory.

It is stated that the advantages of electric power transmission in this factory are most marked, particularly as there are a number of motors operating at considerable distance from the engine room, and

the losses would undoubtedly be excessive were main shafting and belt transmission employed for supplying the necessary power.

A TYPE-PRINTING TELEGRAPH.

A new kind of telegraph printing apparatus, which was introduced in Berlin, Germany, last winter, combines the advantages of the exchange ticker with the telephone service facilities for intercommunication of the subscribers with one another and with the exchange. Dr. Mantler, director of Wolff's telegraph office in Berlin, has taken the matter up, and the apparatus used represents improvements on instruments constructed by Dr. Raps, of Messrs. Siemens & Halske, in 1899, according to the *Engineer and Iron Trades Advertiser*, of Glasgow. Dr. Raps wished to devise apparatus which would enable large firms to communicate their telegraph messages direct to the nearest chief office, and to receive them likewise direct from there without the waste of time which the use of messengers involves. The mechanical power for his printing apparatus was derived from springs, to be wound up at intervals. This is now got from an electric motor. When the spring is wound up sufficiently, two carbon disks are separated from one another, and the motor is thereby cut out. The disks are themselves turned, so that the contact surfaces are kept clean. The instruments are type-printers of simple construction; the printing magnet does not respond to the alternating currents which turn the type-wheel, and the latter is arrested when the current remains steady for a little while. By 1901 the apparatus had so far been improved by Stechern, as we see from the description which Adolf Franke gave before the Elektrotechnische Verein in December, that the telegraph department granted a concession. According to the agreement, the subscribers of the company enjoy the facilities above explained, and the company may further send group messages, as by the telegraph tickers. Since the apparatus must always be ready to receive and print a message, special switches had to be devised for these group messages. These switches interrupt any private communication which happens to pass, and, as long as the group signals continue, a small incandescent lamp glows in every instrument. Messrs. Wolff circulate their political news and the stock quotations in this way. The telegraph department is by privilege empowered to take its wires along the public roads; the company has, however, to come to terms with the authorities as regards this point. Originally, currents of four volts and of eight milliamperes proved sufficiently strong to work the relays, but as the earth potentials amount frequently to several volts, the batteries of accumulator cells had to be strengthened to 12 volts, giving currents of 12 milliamperes. Metallic loop circuits are applied only when indispensable. The new instruments compete, of course, with the telephone, and the central offices are arranged like telephone exchanges.



Electric Crane in Electrically Operated Piano Factory.

MICA AND ITS APPLICATIONS.*

BY J. C. B.

Mica is a substance that is now so very common, that to conjecture as to what would have been the influence on electrical industry had the substance not been a commercial article would be difficult; indeed, as regards electrical progress, mica has always been, as it were, ready at hand to aid any discovery or improvement. On the discovery of the principles of the self-excited dynamo, which marked the advent of both a scientific and commercial evolution, it seems a most fortunate coincidence that such a material should have been to hand, and one that so successfully filled in, so to speak, the interstices of modern progress. Just before this time some practical use to which mica could be applied was being diligently sought after; now, however, what is required are new sources of supply to cope with the multifarious demands for the material. The substance has become now as essential to every branch of electrical engineering as electricity itself seems to be to human progress.

From a geological point, mica, slate and gneiss are the oldest stratified rocks that we are acquainted with. That it was known in past ages is evident from the many marks of ancient operations to be found in mines, and in so many places, for the material was employed for windows, mirrors and ornaments in the early days. In some form or other mica exists all over the earth; it may be found in granite and quartz, rubelite, green tourmaline, feldspar, lepidolite, and many other minerals. It varies in color from white through green, yellowish and brownish shades to black, and its color is greatly influenced by the mineralogical peculiarities of the rock in which it occurs or has been associated, and its commercial value varies also with these circumstances.

One of the most important properties of mica, and one on which its value depends, is the remarkable property of lamination, its structure being so perfect that it is possible to divide it by cleavage into leaves $\frac{1}{250000}$th part of an inch. In consequence of its powerful insulating property, and also the very great advance made in electrical industries, the demand for mica at the present day in almost every country is so great that the supply is almost inadequate. It is not only the superior insulating property of the mineral that gives it such an advantage, but its characteristic and peculiar structure which makes it so adaptable as an insulator requiring very little machining or shaping; for instance, it is a substance which could not be well replaced as an insulator of commutator segments, for it is not only the best but an efficient insulator under every condition. In the case of the commutator its hardness makes it invaluable, for it wears away under the friction of the brushes nearly at the same rate as the hard-drawn copper of the commutator itself.

Further, the fact that heat has no injurious effect on either its physical structure or insulating property, makes it almost indispensable in armature construction, safety appliances, and a multitude of industrial applications, such as lamp chimneys, smoke radiators or preventers, and all purposes where transparency, infusibility, and toughness are required. As is the case with the incandescent burner chimneys, it is also taking the place of gas in many respects,

*From the "Electrical Engineer," London.

especially on board ship, where its combined transparency and tenacity enable it to withstand the wear and tear and the concussion of heavy firing. The qualities of elasticity and toughness are properties in which it is not excelled by anything natural or artificial. These properties are taken advantage of in its employment as an absorbent of nitro-glycerine, and when so used explosions by percussion are rendered less liable, while at the same time nothing is taken from the nitro-glycerine; and for such purposes the pulmose mica is used, or that kind in which the scales are arranged in a feathery form.

The unalterable nature of the substance and its resistance to the corrosive action of acids, smoke and dust, make it also invaluable as a decorative material; the French silver mouldings are made with ground mica, which is accomplished by passing the prismatic or foliated material through a mill, which process increases the bulk forming a mass of translucent and beautiful bean-like scales. Mica is also now being used extensively as a lubricant, and for such purposes it has no superior, except plumbago; it is likewise employed for boiler covering, as roofing material, and as fireproofing for safes, etc. As a reflector of light it has many applications, for it can be readily stamped into any desired shape. At the present time such reflectors are on the market in very many varieties, being admirably adapted to electric incandescent lamps.

Probably the most interesting and beautiful properties of mica are its optical, which, in connection with polarization of light, are both edifying and instructive. Mica under such conditions is what is called a biaxial crystal, which cleaves perpendicular to the bisector of the angle between the optic axis. Its properties in this respect are used for instructive demonstrations of the property of thin films.

There are so many ways of utilizing scrap and cuttings of this material in the manufacture of other insulating substances, such as micanite, etc., that it is almost impossible to find any real mica that may be pronounced useless.

Belgian Commission Decides for Electricity.

A special Dutch Belgian Commission appointed to advise as to the motive power to be adopted for working gates, cranes, swing bridges, etc., at the new Terneuzen docks has, after visiting the principal ports in Germany, England and France, reported in favor of electricity.

SAFE PRESSURES FOR STEAM BOILERS.

ARTICLE I.

BY W. H. WAKEMAN.

A certain applicant for an engineer's license was asked to determine the bursting pressure of his boiler, to which he replied that it was unknown because it has never burst. This answer has been published in several papers, and has furnished amusement for hundreds of readers including the writer.

However, the answer is very suggestive, and I will venture to say that there are two classes who will partially or wholly indorse the same. One is composed of those who have not given the matter any attention, and the other consists of engineers who have studied the subject a great deal.

In explanation of this apparent inconsistency, I would say that those men in charge of steam plants who have not given the matter due attention are not supposed to know anything about it, nor have any ideas on the same, and nobody will be surprised at this, but the statement that those who have carefully studied the subject, are still in doubt about the answer, requires explanation, and the real object sought in presenting this series of articles is to give this explanation in a way that I hope will be satisfactory to those who read all of the statements made, and then study them.

After an engineer has gained a little knowledge on this important subject, he can answer any question along this line that can be asked, but further consideration and study convinces him that while the answers obtained by given rules and formulas when applied to various boilers, are undoubtedly correct, provided the conditions are fully and correctly stated, yet there are so many things to make allowance for, some of which are difficult to fully understand, that the final answer cannot be stated with confidence in all cases.

It is much easier to determine a pressure under which a given boiler will be safe, and this is a strong point in our favor, because this is a matter that concerns us more than the bursting pressure.

The safe pressure is based upon the bursting pressure, and this would seem to indicate that a knowledge of one assures a perfect understanding of the other, but this is not necessarily true, for the simple reason that the vast difference between them allows so much latitude that we have a good chance to avoid over-pressure.

For illustration of this suppose that the bursting pressure of a boiler is 750 pounds, and 5 is adopted as a factor of safety. This gives 150 pounds as the safe working pressure, and it certainly ought to be safe, for if the former has been correctly determined there is a difference of 600 pounds, therefore if the latter is exceeded by 25 pounds in practice, there is still a margin of 575 pounds.

The uncertainty in the matter is due to the fact that when we apply a given rule to a case in hand, we are not sure that all of the conditions are well known, and as we are certain that some points in the design of our boilers are not fully covered by even our best rules, the only plan that insures a reasonable degree of safety is to allow a wide margin and then not exceed the limit so fixed.

The latter statement is easy to make but not so easy to carry into effect at all times, and it is necessary to break the rule but once in order to do a great deal of damage, provided conditions are just right. Of course it is easy to fix the theoretical safe pressure, set the damper regulator at about 5 pounds less, then place the safety valve weight so that it will lift at the safe limit and prevent further increase of pressure, but this is not all that must be taken into consideration.

Some of the strains due to uneven contraction and expansion, are much greater than direct pressure ever brings upon the several parts, and these are not indicated by the pressure gauge.

Shocks caused by disturbance of the water, although not frequent, are still to be counted among the agents which act for the destruction of boilers, as the writer is well aware of from personal experience.

Uneven distribution of the total load is another cause of trouble that it is very difficult to eliminate. This may be caused by failure of one part, making it necessary for some other to do double duty. When first set, a boiler may rest evenly upon its supports, but later on one or more may settle, thus altering the case, and changing a portion of the load.

When calculating the bursting pressure it is necessary to assume that the parts possess definite strength as a basis, but they do not always have the strength, hence a reduction on this account is warranted.

The tensile strength may be less than the engineer supposed, for in many cases only an estimate can be given. A laminated plate may be the cost of the reduction, for when the several layers of an iron plate become partially separated from each other, the strength is reduced there-

by. If the plate is crystallized, or in other words, where the small parts which compose the plate lose their tenacity largely, it becomes brittle instead of tough, so that although the required thickness remains unchanged the real strength is reduced.

The plate may not be as thick at all points as it is assumed to be, for although modern machinery produces very good results along this line, defects are sometimes found. These may appear as thin spots extending over a comparatively large area, or as affecting only a small surface, yet they are both dangerous.

The riveted joints may not be as strong as calculation asserts, as the rivets may not be as large as regulations call for, and even if full size, imperfect spacing of the holes may cause bad defects in the rivets.

Where old boilers are concerned, corrosion and grooving may have gradually made the plate less efficient.

OPPORTUNITIES IN THE ELECTRICAL FIELD.*

BY GEORGE A. DAMON.

The electrical business is a complicated one and is constantly undergoing changes. By the time a method or system becomes standard enough to be looked upon as a precedent, a tendency develops in some entirely new direction. The men who succeed in electrical work must therefore be quick to grasp the lessons of the past, must be ready to appreciate the limitations of the present, and above all should be alert to seize the opportunities for improvement.

The leaders in the various branches of the industry during the first developments, when electrical work was an art and not a science, were graduates from the well-known university of "Hard Knocks." The men of the second generation of workers who are now doing things are largely the product of a semi-scientific training in schools of technology, supplemented by experience of a practical nature picked up in a more or less haphazard way. A few years more will see the development of a third and better-prepared generation of electrical experts, and it is safe to say that they will be the result of a combination of practical training thoroughly mixed with theoretical education. As it must be expected that the next generation will be superior to the present one, will it not be well to stop for an instant in the strenuous rush for results and make a few suggestions which may be of assistance to our successors in planning their life work?

"Work harder," "dig deeper," "put in a better cement foundation," are the keynotes of the suggestions which our older brothers give us as the result of their experience; and the ambitious young man will be quick to recognize the value of their advice. But what is wanted most is some definite information as to how to spend the time devoted to preparation in the most efficient manner, and how to get the benefit of a combined training in theory and practice in the most effective way.

That those who have traveled well on their way toward their goal have many opportunities to point their way to the ones behind, is well indicated by recounting a recent conversation with a boy of 18.

"I am a senior in the High School," he said, "and I want to become an electrical engineer. What shall I do?"

He was strong, bright, ambitious and willing to work.

"Some men tell me to take a college course first, and enter practical work afterward; some tell me to get a few years' experience first, and then take a college course; while still others tell me to study several years, work a year or two, and then finish my senior year. In planning my course, should I include the language studies, or cut them out in favor of shop, laboratory, or commercial courses? Should I try to get through in three years, or should I extend my college education over a period of five years? Others tell me to leave out the university work entirely, go to work in the shop or upon construction work, getting what theoretical training I require by attendance at night school or by taking a correspondence course. What shall I do?"

And there are some of us who will appreciate the young man's bewilderment.

Knowing that the leading electrical men of Chicago would afford a valuable field for studying results and would welcome an opportunity to help furnish a solution for the problems of the boy, a letter of inquiry was sent to 100 of the leading men in Chicago engaged in the various branches of the electrical industry. An opportunity was given at the same time for the expression of opinion on various questions pertinent to the general subject. The response to the circular letter was hearty and spontaneous; and we are under obligations to 100 of our friends who have so kindly consented to become living examples, and who are willing to be analyzed for the good of the cause. The following is an analysis of results:

Young men control the business. The inquiry was, therefore, confined to men between the ages of 27 and 45, upon the theory that the older men are the product of a set of conditions which have passed away, while the youngest men are, as a rule, still engaged in a period of preparation. The average age is 33½ years.

The average income at each age shows an earning of $2,170 at 27, and this increases to $4,000 at the age of 38. The average income of the entire 100 men is $3,440 per year, which will give us a standard by which we can measure the different branches from a mercenary standpoint.

The 100 men may be divided into groups as follows:

	No. of men.	Average age.	Average income.
Salesmen	7	33	$2,400
Sales managers	11	36	3,400
Business men	10	36	4,800
Sales engineers	8	35	2,350
Electrical engineers	16	33	2,800
Constructing engineers	6	33	2,850
Electrical experts	8	33	3,200
Operating engineers	3	32	2,250
Operating managers and superintendents	10	34	3,550
Professors and editors	8	34	2,500
Patent attorneys	4	32	4,000
Consulting engineers	9	40	6,400

Total number of men, 100. General averages: Age, 33½ years; income, $3,440.

Classified in reference to incomes, the record is as follows:

	No. of men.
Income over $10,000 per year	5
Income between $5,000 and $10,000	9
Income between $2,400 and $5,000	66
Income below $2,400	20
Total	100

It should be stated that there are in Chicago at least 100 more men in the business whose incomes will average about the same as the first 100 selected. An effort was made to make the list representative, and the men were selected on account of their positions without reference to their incomes.

It is to be understood that the dollar is not the most desirable standard by which to measure men individually; but looked upon as a class, a study of the averages furnished by the inquiry is interesting and may be made instructive.

Salesmen who have technical ability or possess engineering information, as a rule, get better salaries than those who do not. Add initiative and executive ability to the salesman's qualifications, and he becomes a sales manager with a still greater re-

*Abstract of paper read before the Western Society of Engineers, Chicago, March 18, 1904.

ward. Enterprise and energy put the man in possession of his own business, or often result in a partnership arrangement. A technical man without the commercial instinct is only fairly well paid. Ability to develop new methods or apparatus puts him in the expert class where the rewards are greater and in proportion to his ability.

Routine work, such as operating, is the least rumunerative work of all. Operating managers and superintendents, however, are very well paid.

The phenomenal development along all electrical lines, and particularly in the telephone business, makes the profession of patent attorney a paying one for those who are qualified for that kind of work.

The field of consulting electrical engineering looks attractive; but it will be noted that the average age is greater in this branch than in the others, which means that the successful consulting engineer brings to his work years of experience, and that it is therefore not a branch to be adopted at once by the young man.

Forty per cent. of the men in the list are employed by what might be termed the "large" companies.

Thirty-five per cent. of the men either control the business in which they are engaged or own a partnership interest.

Twenty per cent. of this 100 successful men never had any college education whatever.

The average age of the 20 men who are succeeding without a college education is 36 years, and their success measured by a monetary standard shows an income of $3,670 per year.

It will be noted that the 20 men without the education are getting along financially slightly better than the general average of $3,440 per year. This is explained by the fact that in their number are included several men who are prospering as a result of their business enterprise.

There are few non-technical men engaged in the strictly technical end of the business who reach the average income. There seem to be more openings for the man without a college training in the telephone field than in any other.

Each of the 100 men included in the inquiry was asked to name the three fields which he considered most promising within the immediate future, and the votes received were as follows:

Electric railway work	63
Telephony	36
Transmission	30
Electro-chemistry	29
Power applications	21
Lighting developments	12
Manufacturing	11
Central station work	9
Patent law	6
Consulting engineering	6
Contracting	5
Management of properties	5
Storage batteries	4
Reconstruction of plants	3
Mining	3
Metallurgy	3
Turbines	2
Wireless telegraphy, designing, high-speed telegraphy, underground-conduit construction, isolated plants, train lighting, and municipal lighting, each	1

Practical experience is as essential as theoretical training. Too little attention has been paid by students in getting into thorough contact with the way things are actually done. This is the result of the general practice of allowing the young man to shift for himself. "I can't get a job without experience," he says, "and I can't get experience without a job;" and then more or less discouraged at the outlook, he takes the first opening which presents itself, and it may or may not be the kind of work for which he is fitted. What is needed is a general clearing-house of information, a closer union between the ambitious student and the successful men who have been pioneers in the work. The electrical business has now progressed so far that the actual experience essential for the highest success along any one of its various lines can be generally indicated by experts familiar with the ground to be covered. It is time, therefore, to abandon a thoughtless and perhaps selfish attitude toward the beginner, and make some organized effort to map out the territory which he must travel with guide posts and signs marked: "This way to the front."

The trouble with a great many young men is that they don't "find" themselves early enough in life. They fail to realize the possibilities, and are not prepared to grasp their opportunities. Ambition, aptitude, preparation, and hard work are the stepping stones to successful attainment. Let the ambition to excel be deeply seated, and directed along the line of natural endowment; let the purpose be firm; and, as day follows night, the preparation will be thorough and the man will be known by his works. "If I had it to do over again I would pick out some definite line of work suited to my talents and work like fury," is the advice of many successful and even unsuccessful men.

The purpose of this paper is to encourage a general discussion, which may be of some help in arousing the latent ambitions of the young men who have not selected their life work, by showing them the boundless opportunities of an undeveloped science; to encourage the efforts of the students in our colleges by presenting the results which have been attained by their predecessors; to crystallize the sentiment in favor of a scientific combination of theory and practice; and, finally, to give an opportunity to the men on the fighting line to point the way to their successors, who must come to the front prepared in every way if they intend to take some part in the phenomenal developments which are to be expected.

In order to direct the discussion along definite channels, the following is offered as a suggestion to a young man seriously considering engaging in the electrical business:

In General.—The purport and intent of this specification is to cover the labor and material required to produce in complete working order a man prepared to attain his own ideal of success in that branch of electrical work he may elect.

It is to be understood that the omission of the mention of small details in this description does not obviate the necessity of their being furnished. What is wanted is a thoroughly trained, well-seasoned, broad-minded man, complete with an individual character, a strong intellect and a sincere purpose.

Plans.—He will form his ambition early in life.

He will take a natural interest in the history of men of eminence in his chosen work, and their achievements will inspire him with a desire to accomplish great things.

He will develop his imagination, and constantly broaden his conception of his own possibilities.

He will seek to learn what the world wants and will then endeavor to train his natural abilities so as to supply that want.

Foundations.—He will as a boy develop a knack of "doing things" either as a mechanic, as a draftsman, or in some boyish business enterprise; and a combination of any two or all three proclivities is desirable.

He must early learn the advantage of doing some one thing well; but he should not allow praise for his proficiency to encourage him to neglect study along the lines he does not naturally fancy.

He will not let the attractions of practical work interfere with his intentions to secure the best theoretical and technical training the country affords.

Capacity.—Even if the young man possesses only ordinary talents, his capacity

for hard, conscientious, intelligent, well-directed work will attract attention and win advancement.

When the occasion demands, he will be able to stand a long run on overload or respond to excessive demands for short periods without permanent injury.

He will be able to direct others, and will not depend entirely upon his unaided efforts for results.

Operation.—He will work quietly, and will be turning in the right direction every minute in a simple, direct and accurate way.

He will join that great army of workers who are actually doing things, rather than that smaller class of men who occupy most of their time telling what they are going to do.

He will make friends among his superiors, who will respect his ambitions and will be glad to assist him in realizing his ideals.

He will study men and know how to deal with them.

Work to Be Done by Others.—Parents should study their children and encourage them to develop their natural tendencies.

More occasions should be made for successful men to meet students and give them the benefit of their advice and experience. The students should not be isolated in a little world of their own, but should be brought in contact with an atmosphere of actual affairs.

Shop Tests.—If he enters the shop or testing department of a manufacturing company, he will make a bargain which will result in his getting an all-around experience in exchange for his services, and while in the shop, will keep "on the move" in every sense of the word.

He will seek to make himself thoroughly practical in all his ideas and methods of work.

Fittings.—He will find it necessary to possess accurate knowledge of nearly every branch of science, including physics, chemistry, mathematics, mechanics, pneumatics, hydraulics, mining, metallurgy, and civil engineering.

He must know something about accounts and a great deal about business and commercial law.

He will find that the electrical business is so broad in its scope that a natural aptitude in any direction can be made of use.

Completion.—He will make every sacrifice to get a thorough preparation and a broad experience up to the age of 28 or 30 years.

He will accomplish much between the age of 30 and 45, at the end of which he will be well settled in his business or profession. Let us leave him at this time to inherit his own. May he live long and prosper!

STEAM TURBINE DEVELOPMENTS.*

The future possibilities of the steam turbine, both for land and marine purposes, represent a question which is attracting a considerable amount of attention in different parts of the world at the present time. Apart from Great Britain, the United States, Germany, Switzerland, and France are now seeking to take a prominent part in the development of the turbine engine, and each country has made a certain degree of progress. A short time ago we referred to the formation of an American-German turbine combination between the various companies represented by the General Electric Company of New York and the Berlin Allgemeine Elektricitats Gesellschaft, which is now entirely absorbing the Union Electricity (Thomson-Houston) Company of the same city. It will be recollected that the object of this combination, which is the first immediate result of the establishment of friendly relations, supported by binding agreements, for the interchange of patents, experience, and inventions between the New York and Berlin companies, is to develop the American Curtis type of turbine, in conjunction with that devised by Professors Riedler and Stumpf in Germany. For this purpose two separate companies have been formed under joint auspices in Germany, one being to promote the patents and the other to construct the engines. At first sight it seemed that the combination aimed at the introduction of keen competition with the Parsons steam turbine, which has not only earned an excellent reputation in certain countries of continental Europe, but has also been adopted to a large extent in central stations; while orders for two marine engines of 6,000 hp. and 10,000 hp. respectively for the German Navy were placed some time ago with the Swiss firm of Brown, Boveri & Co., who are the European licensees for the Parsons turbine.

Recent events, have, however, shown that the desire exists, at all events in interested circles in Berlin, for co-operative action with the licensees of the English company. This is illustrated by the fact that of the increase in the share capital which has just been sanctioned from $15,000,000 to $21,500,000, the Berlin Allgemeine Company is devoting a portion to the acquisition of one-half of the share capital of the Brown-Boveri Company. The arrangement to this effect has been made with shareholders in the latter company, and is not necessarily the subject of an agreement with the directors. The formation of one turbine combination, interesting as it may appear, has actually been followed by the constitution of another, and what is of equal importance is the evidence that the other great German electrical group is concerned in the second syndicate, together with certain leading firms in the mechanical engineering branch in Germany, Switzerland and France. The new combination, which has been established to promote the use of the steam turbine devised by M. Zoelly, of Esher, Wyss & Co., of Zurich, comprises the latter company; the Frederick Krupp Company, the North German Machine Works Company, of Bremen, the Siemens-Schuckert Electric Works, and the United Augsburg and Nuremberg Machine Construction Company, while the Schneider Company, of Creusot, is said to be also included in the syndicate. In contradistinction to the first turbine combination, it is not proposed to form a separate company for the development of the Zoelly turbine, which is claimed to have already yielded satisfactory results in actual working. Each member of the new syndicate is, howevever, empowered to construct this particular type of turbine, and the work will be carried out on a common basis in regard to the utilization of drawings, patterns, etc. Of the members of the syndicate, it may be said that the Krupp Company is largely interested in the question from the marine point of view as a result of the company's ownership of the Germania Shipbuilding Works at Kiel, and the desire to gain practical experience with turbine-equipped steamers.

The North German Machine Works Company is a subsidiary of the North German Lloyd Steamship Company, and its participation is therefore of significance. The Siemens-Schuckert Company is naturally concerned from the standpoint of turbines for electric lighting and power stations, while the Augsburg-Nuremberg Machine Company, which ranks as one of the largest and best established steam engine works in Germany, cannot fail to be interested in a type of engine which is making such progress in various countries. There is very little to say in regard to the developments which are taking place, beyond the fact that both in Europe and America the principal electrical and mechanical engineering firms have become alive to the

*From the "Engineer," London.

posibilities of the steam turbine in the near future. In the United States the Allis-Chalmers Company, which has among its directors Cornelius Vanderbilt and E. H. Gary, of the Steel Trust, is reported to be on the point of embarking upon the construction of steam turbines in competition with the Westinghouse and General Electric Companies, whose turbine systems are both being introduced in Great Britain. But whilst the promotion of turbines is welcome, and will, doubtless, result in a large amount of business, there is, of course, another side of the question, namely, how will this particular business affect the trade in reciprocating steam engines? Herr C. Lueg, president of the Association of German Machine Construction Works, drew a gloomy picture of the outlook for the makers of steam engines and boilers at the annual conference held recently, as a result of the increasing competition of gas engines and steam turbines.

We can, however, scarcely share his pessimism at the present time, seeing that although a few instances exist where the newer types of motors have superseded the old, there is no absolute proof that the total horse power of the steam engines and boilers in use has been reduced, or that a material diminution in the output of new engines and boilers has taken place. What has really happened is, regarded from the total horse-power point of view, that the aggregate demand for power has largely increased, and the latest types of prime movers have obtained a share of this augmentation. Whether a decline in the building of steam engines and boilers will eventally take place is a question which may safely be left to the future to decide. The electric light has not reduced the consumption of gas, nor has the introduction of electric motors made any material difference in the number of small gas or steam engines to be found in different parts of the country.

A Coal-Testing Plant at St Louis.

Among the interesting exhibits connected with the Department of Mines and Metallurgy at the Louisiana Purchase Exposition will be a coal-testing plant operated under the direction of the United States Geological Survey. The tests will be conducted not for the purpose of determining the relative value or merit of different coals, but primarily for the purpose of demonstrating the most economical methods for their utilization.

The testing plant will comprise two standard boilers, a gas producer, coke ovens, washery plant, and two or more briquetting plants. In connection with the boilers one Corliss and one steam turbine engine will be operated, and in connection with the gas-producing plant one explosive gas engine. The power generated by these plants will be utilized for operating the working exhibits in the Mines Building. The testing plant will be located on the ground reserved for outdoor mining exhibits, at a short distance from the Palace of Mines and Metallurgy. The director of the Survey has appointed to conduct this work a committee consisting of Messrs. E. W. Parker, J. A. Holmes and M. R. Campbell.

The equipment for carrying on these tests has been loaned by the exhibitors of the machinery, and Congress has appropriated $60,000 to enable the director of the Geological Survey to make the tests. It is especially provided in the Act of Congress making the appropriation that all the testing machinery and all the coals tested shall be furnished without charge to the Government, the expenditure of the appropriation being limited to the absolute cost of assembling the plant so as to make it conveniently available for the work and the expenses necessarily incurred in its operation. Not only will physical tests be applied, but each carload of coal will be carefully sampled and the composition of the samples determined under the direction of the chemical laboratory of the Geological Survey.

The material to be tested will be collected under the direction of Mr. M. R. Campbell, of the Geological Survey, who will procure the co-operation of the various State geologists. Great care will be exercised to see that the samples sent for testing represent the commercial product of the mines or districts from which the coal is shipped and are not selected samples. No tests will be made of any coals shipped in less quantity than one good-sized carload, as it will require from 8 to 20 tons for each of the different tests to which the coals will be subjected.

The work possesses a peculiar interest from the fact that this Government has not heretofore attempted to make any uniform and comprehensive examination of our mineral fuels. The Governments of Great Britain, Germany, France, and Belgiun have made such examinations and published the results in official reports, which are of great value in securing foreign trade. They have also had an undoubted influence in encouraging the establishment of manufacturing industries in territories accessible to any fuel that is especially adapted to the needs of those industries.

MARCONI'S LATEST EXPERIMENTS.

In Constant Communication With Land in England and America on Voyage to New York.

Mr. William Marconi arrived in New York on Saturday last on the Cunarder Campania, and he informed reporters that all long distance wireless transmission records were broken by his latest apparatus:

"From the day we sailed we were in communication with England or America," said Mr. Marconi. "For 1,700 miles we received messages from Poldhu on the Cornish coast. Then we dropped that station and picked up American stations without trouble.

"None of the American stations has machines like the one I brought with me. If they had we would have picked them up and transmitted our English news from Poldhu to America. There was no hitch in transmitting or receiving.

"The regular Cunard line apparatuses are short distance machines, with a range of 150 miles at most. In two weeks they will be substituted by duplicates of the machine I used on this voyage, and transatlantic wireless Marconi cables will be an assured fact.

"The publication of the transatlantic morning paper will follow. With the new model in every station transmission is beyond question.

"These machines I bring with me are for receiving only. Equally powerful transmission machines can be made, but for the purpose of publishing a newspaper on the ocean they are a success.

"My idea for a mid-ocean newspaper was regarded skeptically by the Cunard people. They wished me to make a personal test. Now on my return voyage I will demonstrate that an ordinary operator can do the work.

"I have contracted to connect our shore stations with the British postal service and to equip twenty new passenger ships.

"My next experiment will be that of girdling the globe by means of instruments on vessels at sea. The British Government has placed several of its warships at my disposal, and the next three months will be devoted to fitting them with the long-distance keys and receivers. Then they will be stationed at different points around the world, and I shall try to pick each one up in succession.

"The only instruments that can take our messages are those keyed up just as ours are, and to do that is so nearly impossible that I say it cannot be done.

"I expect to remain over here only a

week or two, the length of my stay depending on whether I shall have to visit my station in Canada. On my return to England I shall continue the experiments from this side in connection with the Cape Cod station. After that the work will be carried on by the regular operators.

"The instrument to be adopted will be a modification of the best of all that was good in the four types in use. It has a multiplication of my receiver, and will always be in communication with either the eastward or westward shore of the Atlantic, and a ship on which the apparatus is installed will never be out of touch with land."

Mr. Marconi was accompanied by his assistant, Mr. Kemp; two special operators, two secretaries and W. W. Bradfield, who assisted in the experiments during the voyage. Communication was maintained with Poldhu after the Campania had picked up the station on Cape Breton Island.

It is said that the new Marconi news service will cost the Cunard Company $50 per day. Mr. Marconi said that he expected the new ocean news service would be in great demand, and that is why he wished to determine upon a standard receiver.

Clergyman Says He Beats Marconi.

A dispatch from Wilkes-Barre, Pa., May 15, says that Rev. Joseph Murgas, of the Sacred Heart Church of that city, has received notification from Washington that the sixth and seventh patents have been granted him on a wireless telegraphy system he has invented. He says it is better than Marconi's, because it can send and receive messages in half the time. He has been engaged on the invention seven years.

Electric Patent Case Decision.

Judge Bradford, in the United States Circuit Court at Wilmington, Del., handed down a decision in the case of the Westinghouse Electric & Manufacturing Company vs. American Transformer Company. The Judge held that the claim for letters patent 366,362, dated July 12, 1887, issued to George Westinghouse and by him assigned to complainant is valid and has not been infringed upon by the defendant company, and therefore dismissed the bill. The patent relates to an improvement in electrical converters.

Obituary—Andrew Hickenlooper.

Gen. Andrew Hickenlooper, president of the Cincinnati Gas & Electric Company, died in Cincinnati last Friday.

The Edison Medal Competition.

President Arnold, of the American Institute of Electrical Engineers, has addressed to the educational institutions of the United States and Canada a statement with regard to the Edison Medal founded this year, and calling their attention to the fact that it is open for competition by students for the best thesis or record of research on theoretical or applied electricity and magnetism. Mr. Arnold announces that the medal committee of the Institute is being formed and requests the authorities of institutions qualified and desirous to compete to send in their names to the medal committee, at 95 Liberty Street, New York City, on or before June 1, when further information will be given. It is expected that there will a large competition from among the graduating students in electricity.

Society of Chemical Industry.

The last meeting of the New York Section of the Society of Chemical Industry will be held at the Chemists' Club, 108 West 55th street, on Friday evening, May 20. The following papers will be read: "Method for the Rapid Estimation of Boric Acid," by M. F. Schaak; "Notes on Reduced Iron," by A. H. Gotthelf, and "The Hazard from Explosives and Combustibles in the City of New York," by Charles F. McKenna.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 10, 1904.

Electric Railways and Appliances.

759,241-242-243-244. Electric-Railway System. George L. Cragg, Chicago, Ill., assignor to Bion J. Arnold, same place. Filed May 22, 1902.

759,327. Railway Switching and Signaling Apparatus. John D. Taylor, Buffalo, N. Y., assignor to the Taylor Signal Company, same place. Filed Oct. 25, 1901.

759,346. Railway-Block Signal System. Winthrop M. Chapman, Newton, Mass., assignor to the Electric Railway Signal Company, Kittery, Me. Filed May 12, 1902.

759,433. Trolley. Elmer E. Gillingham and Delancey E. Huntley, Wellston, O. Filed April 27, 1903.

759,446. Car-Fender. Frederick R. Keith, Randolph, Mass. Filed June 22, 1903.

759,453. Electric Railway. Timothy Mahoney, San Francisco, Cal. Filed July 1, 1903.

759,543. Electric Railway Signal. Elwood W. McGuire, Richmond, Ind. Filed Aug. 15 1902

759,707. Fender. John O. Harrison, Evansville, Ind. Filed Feb. 8, 1904.

Electric Lights and Appliances

759,506. Means for and Method of Securing Lead-in Wires in Electric Lamps. John C. Entriken and William S. Everett Malvern, Pa., assignors of seven-sixteenths to Charles F. Kindred, Philadelphia, Pa. Filed Jan. 21, 1904.

759,650. Manufacture of Small Incandescent Lamps. Allen D. Whipple, Chicago, Ill., assignor to the Kellogg Switchboard & Supply Company. Filed Dec. 5, 1903.

Electrical Machinery and Apparatus

759,222-223. Power-Transmission Mechanism. Bion J. Arnold, Chicago, Ill.. Filed Feb. 26, 1901, April 26, 1901. Renewed Dec. 13, 1902.

759,237. Circuit-Changer. Charles C. Cadden, Cleveland, O., assignor to the Williams-Abbott Electric Company. Filed June 15, 1903.

759,286. Electricity Meter. Martin Kallmann, Berlin Germany, assignor to the Internationale Electricitats Zahler Gesellschaft, M. B. H., same place. Filed Sept. 28, 1901.

759,288. Electric Brake. Walter Lasar, St. Louis, Mo., assignor of one-half to the Lasar Elevator Company. Filed Feb. 10, 1902.

759,352. Meter for Measuring Electrical Energy. Louis P. Decombe, Paris, France. Filed Nov. 26, 1901.

759,358. Magnetic Separating Apparatus. Thomas A. Edison, Llewellyn Park, N. J. Filed June 21, 1900.

759,426. Electric Soldering-Iron. Sydney Evershed, London, Eng., assignor to himself and Evershed & Vignoles, Limited, same place. Filed Dec. 8, 1903.

759,431. Electric Accumulator. Ricardo Fortun and Eduardo Semprun, Madrid, Spain. Filed Sept. 30, 1901.

759,436. Electrical Warp Stop-Motion for Looms. Henry I. Harriman, New York City, assignor to the American Loom Company, Readville, Mass. Filed Dec. 3, 1901.

759,586. Electric Switch, Henry C. Baer, New York City. Filed Nov. 9, 1903.

759,600. Electrical Switch. Fay L. Faurote, Ann Arbor, Mich. Filed March 14, 1903.

Telephones and Telephone Apparatus.

759,280. Telephone Attachment. Stephen O. Houghton, San Francisco, Cal., and Frank M. Potter, Jr., Syracuse, N. Y. Filed Dec. 30, 1903.

759,316. Telephone-Receiver. Walter C. Runge, London, Eng. Filed Dec. 6, 1902.

759,428. Telephone-Transmitter Hood. Robert D. Fannon, Chicago, Ill., assignor, by mesne assignments, to Delos Dunton, Carpentersville, Ill. Filed Oct. 29, 1901.

759,441. Telephone-Transmitter. Alfred W. Hill, West Hoboken, N. J., assignor to himself and D. P. Chesebro and Alfred E. Davidson, New York City, doing business as the Phonic Carbon Company. Filed Oct. 9, 1902.

759,492. Telephone-Exchange. Clarence A Anderson Salina, Kan. Filed Dec 5, 1901.

759,641-759,762. Signaling Apparatus for Telephone-Switchboards. Edwin H. Smythe, Freeport, Ill., assignor to the Western Electric Company. Filed Jan. 26, 1903; Sept. 14, 1903.

759,697. Telephonic Apparatus. Alfred Graham, London, Eng. Filed Feb. 4, 1903.

759,741. Electric Block-Signaling and Telephoning System for Railways. Charles G. Otwell and Ira H. Melvin, Laurel, Del. Filed Feb. 11, 1904.

759,771. Signal Apparatus for Telephone-Switchboards. De Witt C. Tanner, Chicago, Ill., assignor to the Western Electric Company, Filed March 27, 1902.

759,836. Generator for Telephone-Calls. Ernest H. Strauss, Chicago, Ill. Filed Nov. 17, 1902.

Miscellaneous.

759,276. Insulator for Telegraph-Wires. Clayton Hobert, Philadelphia, Pa. Filed April 10, 1903.

759,281. Signaling. Gustav A. Huber, Mounthope, N. Y. Filed Jan. 9 1904.

759,464. Alarm System. Felix McGloin, New York City. Filed Dec 31, 1902.

759,472. Thermostat. Alfred Roesch, Bridgeport, Conn., assignor to the Davis & Roesch Temperature Controlling Company, New York City. Filed. Jan. 27, 1903.

759,550. Secondary-Battery Electrode. Charles J. Reed, Philadelphia, Pa. Filed Jan. 16, 1901.

759,701. Facsimile-Telegraph Apparatus. Ernest K. Gruhn, Dresden, Germany, assignor to the Telautograph, Gesellschaft mit Beschraenkter Haftung, same place. Filed Nov. 21, 1902.

759,722. Electric Heater or Rheostat. Max C. Krueger, Chicago, Ill., assignor, by mesne assignments, to the Magneto Electric Company, Amsterdam, N. Y. Filed Oct. 6, 1902.

759,740. Battery, Jay Noble and Edward L. Anderson, St. Louis, Mo. Filed June 1, 1903.

759,796. Lightning-Arrester. John C. Barclay, New York City. Filed Sept. 9, 1903.

759,797. Rheostat. John C. Barclay, New York City. Original application filed Sept. 9, 1903. Divided and this application filed Nov. 18, 1903.

759,798-799. Electrolytic Apparatus. Henry S. Blackmore, Mount Vernon, N. Y. Original application filed July 22, 1903. Divided and last application filed Feb. 23, 1904.

759,814. Door-Lock Actuated Circuit-Breaker. Grayson G. Knapp, Auburn, N. Y., assignor of one-half to Charles S. Averill, Syracuse, N. Y. Filed Feb. 13 1903.

759,825. Wireless-Telegraph Apparatus. Joseph Murgas, Wilkes-Barre, Pa. Filed Oct. 2, 1903.

759,826. Method of Communicating Intelligence by Wireless Telegraphy. Joseph Murgas, Wilkes Barre, Pa. Original application filed Oct. 2, 1903, Divided and this application filed Feb. 24, 1904.

THE TELEPHONE WORLD.

Indiana Independent Telephone State Convention.

The Indiana Independent Mutual Telephone Association will hold its annual meeting at Hotel Lahr in Lafayette, June 28 and 29.

This meeting is sure to be of interest and benefit to both the operating companies, manufacturers and supply people attending. There will be able papers prepared and discussions upon topics of vital interest to all Independent telephone people. The leading manufacturers and supply men will make creditable displays of all lines of goods

There will be a programme of entertainment, such as trolley rides, vaudeville shows, music, an inspection of the electrical and mechanical department of Purdue University, banquet and a dance, all of which will be free to the members attending the convention.

The Sterling Electric Company of that city is extending a hearty welcome to its associates, and says: "We want to see every company in the Independent telephone business in the State of Indiana represented at this meeting, and believe it will be to their interest to be represented. Come, whether you are a member of the association or not. There will be no charges for any entertainment. There will be no assessment, but a 'getting together' of all Indiana telephone men for the purpose of holding a harmonious meeting for the advancement of Independent telephone interests. We appeal to you to come and help make the Independent telephone movement in the State of Indiana the strongest and most united of any State in the Union."

To Oppose the Bell Company.

The Union Telephone Company of California, Pa., was lately granted a franchise to place poles and wires through Roscoe by the borough council. The company will establish an exchange and start an active canvass in opposition to the Bell and Federal telephone companies. The rates for 'phones to be installed by the new company are lower than Federal rates by nearly 35 per cent.

At a recent meeting of the citizens of Junction City, Ky., a company was organized for the purpose of installing a telephone exchange. The following officers were elected: President, Dr. J. R. Steele; vice-president, R. H. West; secretary, J. D. Shelby.

The Pennsylvania Telephone Company is erecting new poles between Hamburg and Windsor Castle. A new telephone line is being constructed from Windsor Castle to Dreibelbis, Virginville, Lenhartsville, Klinsville and Kempton, Pa.

The annual meeting of the Mexican Telephone Company was held in this city last week. C. H. Rollins was ré-elected president and W. French Smith, secretary. There was a single change in the board of directors made necessary by the death of Mr. Brice. The report of Treasurer Smith showed the company to be in a prosperous condition.

The Orfordville, Wis., Tel ephone Company, by O. P. Goorder, president, and T. E. Tollefsrud, secretary, has issued an amendment increasing its capital stock from $10,000 to $15,000.

Home Company in Albany Prosperous.

The annual meeting of the stockholders of the Albany, N. Y., Home Telephone Company was held at the office of the company a short time ago.

At a meeting of the board of directors, held at the conclusion of the stockholders' meeting, the following officers were elected: Howard Hendrickson, president; Irving H. Griswold, vice-president; George C. Lee, Jr., treasurer, and H. J. Prince, Jr., secretary.

The affairs of the company are in a very flourishing condition. The annual report submitted at the stockholders' meeting shows a net increase of 1,159 telephones for the year, or about 100 increase per month, with about 200 contracts on file waiting for installation. New contracts are being received daily. The report also shows that the company, after operating for 15 months, has an earning on stock of 9 per cent. after paying for operating, maintenance and all fixed charges.

Up-to-date Company in Albion, N.Y.

The Home Telephone Company of Albion, which was recently organized, Rochester and Albion capitalists being interested, has commenced work on its new plant, and is anxious to open the service next July with the most modern telephone plant in the United States. One great feature claimed for the new system is private service on all lines, both city and county. This is secured by the use of the "Stromberg-Carlson Selective and Lock Out System."

The signal to central will be the central energy call, similar to the Rochester and Buffalo Independent telephones, discarding the use of old-time hand generators.

The Home Telephone Company of Albion will connect with the Lakeside Company at Waterport, which will give the Albion merchants an equal chance to secure the patronage of the great host of farmers of the Ridge Road, who are now daily in touch with the markets of Medina by the use of Independent telephones. The motto of the Home Telephone Company will be, private service, prompt service, popular service and perfect service. Garrison Babcock, a telephone engineer of Rochester, is in charge of the work and has a large force of men employed.

A suit has been started in Media Pa., by the United Telephone & Telegraph Company to recover $30,000 from the Bell Telephone Company for the alleged destruction of wires during the sleet storm of February 21, 1901. The United Company alleges that the Bell people cut the former's wires, entailing great loss.

The Cooperstown, N. Y., Telephone Company certified to the Secretary of State that it has increased its capital stock from $7,000 to $10,000. The debts and liabilities of the company amount to $1,200.

A company has been formed at Woodburn, Ky., for the establishment of an Independent telephone company at that place.

A complete telephone system is to be installed in Lima, Peru, S. A.

Owego, N. Y., Wants Independent Company.

An Independent telephone company is at tempting to secure a franchise in Owego, for the purpose of putting in a local exchange in that village and operating a line in opposition to the Bell Telephone Company. The petitioners for the franchise are Lyman T. Stanbrough, Ward Decker, Fred Ford and John T. Gorman, of Owego, and Nelson P. Brink, of Binghamton.

The proposition of the petitioners is to form a stock company within 60 days and begin the work of installing the new system at once. The rates promised are for a business place, private line, one year, $28; business place, three party line, $20; residence, private line, one year, $18; residence, three party line, $12.

The Independent telephone in Binghamton is an unqualified success, and those who have the service would not think of attempting to do without it again. One of the things the new company has done is to reduce the telephone rates to such an extent that it is now possible for a person to have both 'phones at about the same price that one cost before the new company came to the field, so that the argument that two 'phones would be necessary does not carry much weight, as it would mean hardly any additional expense.

Many of the best people of Owego are in favor of the granting of the franchise and it is expected that the petitioners will be able to obtain the concessions they desire.

An Independent telephone company is being organized in Pottsville, Pa. The council recently declared the franchise of the existing company forfeited because of alleged violations of its provisions.

Henceforth the Cadiz, Ind., Telephone Company in Henry County will have no business relations with the Bell Company. All business in the future is to be done with the Independent companies.

A new telephone system is being talked up in Georgetown, Mass. The People's Company of Haverhill is interested.

Nearly 600 new telephone companies were organized in Iowa last year.

Telephone Incorporations.

The Rural Telephone Company, Hamlin, N.Y. Capital stock, $5,000. Incorporators; D. Singleton and A. Baase, Hamlin.

The Farmers' Telephone Company of Rensselaer County, Hoosick Falls, N, Y. Capital stock, $5,000. Incorporators: Jay C. Cottrell, Perry S. Pine and John B. Hill, all of Hoosick Falls.

The Keeseville Telephone Company Keeseville, N. Y. Capital stock. $20,000. Incorporators: J. H. A. Bond, J. B. Mace and W. C. Palmer, all of Keeseville.

The Linwood Telephone Company, Linwood, Tenn. Capital stock, $1,000. Incorporators: H. D. Beadle, W. M. Young, J. W. Andrews, A. A. McNabb, T. M. Turner and O. D. Hearn.

The North Collins Telephone Company, North Collins, N. Y. Capital stock, $5,000. Directors: W. M. Ward, D. A. Dillingham and H. G. Parker, of North Collins.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Antigo, Wis.—The plant of the Antigo Electric Light & Power Company here was lately destroyed by fire, causing a loss of $20,000.

Asbury Park, N. J.—It is proposed by the people of this place to install an electric light plant of their own.

Avoca, Ia.—The Avoca Electric Light Company is contemplaing using the meter system.

Colima, Mex.—A company has been organized here with $125,000 capital to generate electric power from the waterfall in the Hacienda de San Antonio. The company will furnish light in this city and for the haciendas in the vicinity. Arnoldo Vogel, owner of the hacienda, can give information.

Culican, Mex.—Carlo Escovar, of this city, proposes to light the city by electricity for a term of 12 years, furnishing 60 arc and also incandescent lamps.

Danville. Ky.—After many years of wrangling the city council has decided to sell a franchise for the installation of an electric light plant.

Fennimore, Wis.—This town has under consideration the establishment of municipal waterworks and an electric light plant.

Jonesboro, Ark—Manager Christy, of the Jonesboro electric light plant, announces that it is to be enlarged.

Moberly, Mo.—The Moberly Light, Power & Fuel Company has been awarded a 10-years' franchise for gas, electric light and power.

Oshkosh, Wis.—William Mainland, of this city, president of the Green Bay Light & Power Company, states that the company is about to double the capacity of its plant and thousands of dollars will be spent in providing new machinery and buildings.

Sebastopol, Cal.—G. W. Sawin has been granted an electric light and power franchise.

Stamps, Ark.—A new electric light plant is to be built here.

Tannersville, N. Y.—The Tannersville Electric Light & Power Company, capitalized at $20,000, has been formed by Charles Penrose, Renwick Dibbell and M. R. Francis, all of Tannersville.

Tazewell, Va.—The Tazewell Electric Light & Power Company has been incorporated with a capital of $10,000 and increased same to $15,000. J. S. Moss is president.

Thomson, Ga.—A system of waterworks and electric lights, to cost not over $25,000, was agreed upon at a recent meeting. James T. Neal, cashier of the Bank of Thomson, has been chosen as chairman, and Paul A. Bowden, cashier of the Farmers & Merchants' Bank, secretary.

West Liberty, Ia.—This city wants a company to furnish electricity for lighting.

Wilton, Ia.—At a special election held here May 2 it was decided to issue bonds to the amount of $5,250 to improve the Wilton electric light plant.

STREET RAILWAYS.

Asbury Park. N. J.—A party of capitalists interested in the proposed trolley road from Freehold to this city, lately went over a portion of the highway to be utilized for the building of the new road which is to run from Freehold to the shore via Colts Neck and Eatontown.

Battle Creek, Mich.—The Battle Creek Electric Railway Company has been incorporated with H. M. Griffin as president.

Cleveland, O.—A large storage battery station will be built in Newburg this summer by the Cleveland Electric Railway Company.

Coldwater, Mich.—The Toledo & Michigan Electric Railroad Company has secured the right of way from Adrian to this city.

Denver, Col.—Electric lines to form a network transportation system to cover the entire northern part of this State will be built, it is said, with the backing of the Burlington Railroad and be feeders for the big system. This will be the first venture of the kind in this section of the country. Two companies have been chartered, one to build from here to Greeley, and the other from Fort Collins to Longmont, where it will connect with the Burlington-Lyons branch.

Elizabeth City, N. C.—D. E. Evans, president of the Elizabeth City Electric Light Company, says that he will organize a company to build an electric railway here.

Geneva, O.—Homer Hood, of Toledo, proposes to build an electric line from this village to the Lake Shore, a distance of five miles.

Hummelstown, Pa.—Work will soon commence on the construction of the Hummelstown & Campbelltown Electric Railway, which will extend from Palmyra to this place.

Jeannette, Pa.—The Jeannette, West Newton & Monongahela Railway Company has arranged to begin construction before the end of the month. The capital is $4,000,000. All rights of way have been secured, and the line will extend across country to the river district of Westmoreland County through a territory with a population of 20,000.

Kansas City, Mo.—R. T. Mastin and G. F. Shields are the promoters of an electric line from Belton, Mo., to this city.

Knoxville, Tenn.—The Knoxville, Traction Company will greatly improve its lines.

Mt. Ayr, Ia.—Wallace Hubbard, an electric railway promoter, of Albany, Mo., will soon be here to make a survey of the proposed electric line from Des Moines to St. Joseph.

Neenah, Wis.—The Wisconsin Traction, Light, Heat & Power Company will build a line to Menasha Park.

Opelika, Ala.—Rush Taylor is the promoter of the electric railway system between this place and Auburn. Every indication points to the early commencement of work on the construction of its line.

Petersburg, Mich.—J. O. Zabel and S. A. Foster have been granted a franchise through Dundee for an electric line from here to Jackson.

Pittsburg, Pa.—The contemplated electric railroad from East Pittsburg to this city, known as the East Pittsburg & Wilkinsburg line, has been franchised.

Salida, Col.—The Chaffee County Electric Light, Power & Railway Company has been incorporated with a capital of $500,000, to construct street railway lines in this city and its suburbs.

Temple, Tex.—The Belton-Temple Traction Company, capitalized at $250,000, has been chartered.

POWER PLANTS.

Ameca, Mex.—George E. McCormick has applied to the State Government for a concession to operate an electric power plant with waters of Las Topenas stream. The power will be used for operating reduction works, which he will erect at his mines in this district.

Granite Falls, Minn.—A company has been incorporated for the purpose of improving the water power at Minnesota Falls, near here, to put in a power house and dynamo, and transmit power to Montevideo.

Marshfield, Wis.—The question of transmitting electricity generated from the large dam recently constructed by the Consolidated Water Power & Paper Company to this city, to light the streets, business houses and residences, is now being seriously considered by the council.

Red Bluff, Cal.—J. H. Leveck has filed notices appropriating 15,000 inches of water from the North Fork of Battle Creek, and for 7,000 inches from South Fork of Battle Creek for the purpose of generating electric power for running machinery.

Salt Lake City, Utah.—The Standard Power Company has in contemplation the erection of a 6,000 hp. electric plant on the Sevier River near Marysvale to furnish power to the mines and mills of the Gold Mountain district, also to supply the camps and towns in Beaver County. E. R. Jones, engineer of the American Geological & Engineering Company, is interested.

BIDS WANTED.

Chicago, Ill.—Sealed proposals are being invited until May 31 for wiring of buildings, furnishing and installing watt and voltmeters, transformers, arc lights and other electric fixtures, and furnishing of necessary current for electric lighting Fort Thomas, Ky., in accordance with specifications and lighting plan to be seen at the office of Lieut. Col. W. H. Miller, Chief Quartermaster, Pullman Building, this city.

Fort Flagler, Wash.—Bids are asked until May 26 for the construction, plumbing, heating and wiring for the electric lighting of a 12 bed hospital here. Address George H. Penrose, Quartermaster.

Washington, D. C.—Sealed proposals will be opened by the supervising architect of the Treasury on May 31, for new magnetic controlling device and new safety devices, etc., for the electric passenger elevator in the United States court house and postoffice building at Scranton, Pa. For specifications address James Knox Taylor, this city.—Mr. Taylor is also inviting sealed proposals until May 26, for the installation of a conduit and electric wiring system for the United States postoffice at Waterbury, Conn.—The bureau of supplies and accounts of the Navy Department is inviting sealed proposals until May 24 for furnishing the navy yards at Puget Sound and Mare Island with a quantity of arc lamps, carbons, incandescent lamps, electric fans and exhausters, transformer, rubber insulated copper wire, conduit and fittings, etc. Bidders can obtain specifications, etc., upon application to the bureau in this city.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, $13\frac{1}{8}$@$13\frac{1}{4}$c.; Lake $13\frac{1}{4}$@$13\frac{3}{8}$c.; casting, $12\frac{7}{8}$@$13\frac{1}{8}$c.

It is estimated that the electrical work on the New York Central Railroad will cost $12,000,000.

The Blue Grass Traction Company of Lexington, Ky., has filed a mortgage to secure $700,000 five per cent. 30-year gold bonds.

The General Electric Company has declared the regular quarterly dividend of $2 a share, payable July 15 to holders of record June 15.

The Turbine Electric Truck Company of New York has filed with the Secretary of State a certificate of increase of capital stock from $100,000 to $300,000.

The directors of the American Railways Company (Philadelphia) have declared a regular quarterly dividend of $1\frac{1}{2}$ per cent., payable June 15 to stock of record May 31.

The directors of the Public Service Corporation decided to pass the semi-annual dividend of $1\frac{3}{4}$ per cent. on the stock of the South Jersey Gas, Electric & Traction Company.

According to President Insull's annual statement sent to stockholders the Chicago Edison Company raised and expended over $3,000,000 of new capital last year and the Commonwealth Electric Company over $2,250,000.

Mason B. Starring has been appointed general manager of the Chicago City Railway. It was declared that the placing of Mr. Starring in the new position marked the beginning of a new policy and important improvements.

The stockholders of the Fairhaven & Westville Street Railway Company will meet at New Haven, Conn., next Friday to vote on a proposition to sell the property and franchises to the Worcester & Connecticut Eastern Railroad Company.

Earnings of the Interborough Company of New York for the quarter ended March 31 amounted in gross to $3,845,121, an increase of $615,000, as compared with the same quarter last year. Net earnings increased $469,000, while surplus after charges, including the dividend on Manhattan stock, increased $35,000.

Judge Gaskill of the Superior Court, Worcester, Mass., has granted a decree allowing Charles M. Thayer and John A. Hall, receivers of the Worcester & Southbridge Street Railway, to sell the road for not less than $300,000 at private sale. It is understood that a syndicate headed by William E. Rice, of Worcester, will purchase the road, together with the allied lines which were involved in the failure last fall.

It is announced that the $3,325,000 of stock authorized at the General Electric Company meeting last week is now offered to stockholders at par, on the basis of one share of new stock for every ten held. Of the amount offered to stockholders, $2,500,000 will be devoted to paying off the floating indebtedness of the Stanley Electric Company and the balance, $825,000, to the general uses of the company. The rights of the new issue of stock figure up at around $5.50.

The directors of the Massachusetts Electric Companies voted to petition the railroad commissioners for authority to issue $8,432,500 in 4 per cent. bonds for the purpose of refunding the present funded debt and $1,227,500 for the purpose of taking up the present floating indebtedness. The total capital stock of the company is $9,660,000 and the outstanding funded debt $8,432,500, the difference representing the additional amounts to be issued $1,227,500.

ELECTRICITY.

VOL. XXVI. NEW YORK, MAY 25, 1904. NO. 21.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

The Convention.

The National Electric Light Association Convention is now in full swing in Boston. There are an unusual number of excellent papers to be read at this year's gathering and the Question Box forms quite an attraction.

As usual the social and entertainment features will be everything that can be desired. The complete programme of the convention will be found elsewhere in this issue.

Wires to Burn.

As a result of a fire which started in one of the power houses of the Brooklyn Rapid Transit Company the trolley system in the Borough across the river was tied up for over an hour one day last week. Referring to the matter a Brooklyn daily says:

"The cause of all the trouble was a fire which broke out shortly after noon in the cable tower at the Third avenue station. The insulations of the mass of cables through which the heavy current is fed to all the down-town lines became defective and short-circuiting resulted. The fire itself was only a one-alarm affair and was extinguished in twenty minutes."

This burning of the insulation on the cables brings up the question as to why steps have not been taken to compel the Brooklyn Rapid Transit Company to make a move towards placing its innumerable cables and conductors under ground where they belong. We use the expression "make a move" advisedly, for we appreciate the fact that were the above mentioned company compelled to place all of its wires *at once* underground it would probably come very near to going into the hands of a receiver.

In the Borough of Manhattan even a few stray and lonely telegraph wires were recently forced to hide themselves, and yet the city fathers close their eyes to another portion of this great city, where power and other wires are so thick that the residents are obliged to climb to the roofs to ascertain if the sun is shining.

Probably the two greatest extremes in the world in the way of running conductors are to be found in two boroughs of the same city. Manhattan is an example of the modern method, Brooklyn of the ancient.

Brooklyn's wires will have to go underground sooner or later, so a move might as well be made now as five years from now. In order to make it easy, let the city fathers order the wires underground on the installment plan—so many miles a year. This method should not prove onerous to the company, will afford work for the laboring man and make everybody—except possibly the stockholders—happy.

* * *

A Mammoth Undertaking.

At no very distant date the principal railroads in the vicinity of Greater New York will all be obliged to follow the example being set by the New York Central and operate their suburban trains by electricity.

It is stated on good authority that not only will the New York Central make use of electricity in its tunnel as motive power, but that the electric zone will extend as far as White Plains on the Harlem and Ossining or Croton Landing on the main line. When the railroad yards are enlarged (upon which work is now being pushed) they will take in fifty-seven tracks and will extend from Madison to Lexington avenue, and an entirely new distribution of the traffic inward and outward will be made.

The new Grand Central Station, in its

main portico, will be devoted to through train traffic, with twenty tracks. Under this main station will be the suburban system, with from eight to twelve tracks.

The electrification, said Mr. Wilgus, chief engineer of the New York Central, on both the Harlem and Hudson River divisions means extending the electric system from twenty-five to fifty-five miles from the Grand Central Station. The suburban trains will be handled by the multiple unit system, under which every car or two out of three cars will be equipped with electrical motors. Each car is therefore practically self-propelling, so that a single car can be started or fifteen in a train.

For the through trains it has been decided to use electric locomotives, which will be handled with 2,250 horse power engines. The suburban trains will be capable of a speed of seventy-five miles an hour, and it is the intention of the company to eliminate small grade crossings.

The proposed changes will involve an expenditure of about $22,000,000 during the next year.

That the multiple unit system for suburban traffic has a decided advantage over the present system in vogue goes without saying. It should permit of a train of one or two cars being run at much shorter intervals than now, which, as every commuter has found out by experience, is much to be desired. Whether this will be done when the electrification of the road is completed of course depends on the management. It is to be hoped however that it will.

* * *

Radium Causes the Earth's Heat.

Ernest Rutherford, Professor of Physics at McGill University, Montreal, in a lecture before the Royal Institution in London, England, on Friday night, advanced the striking theory that the earth's heat is not attributable to a molten mass which has been slowly cooling for a million years, which has been the generally accepted theory, but to the presence of radium.

A cable dispatch says Prof. Rutherford's address was listened to by a distinguished audience, including Lord Kelvin, Lord Rayleigh, Prof. Dewar and other great scientists.

Prof. Rutherford, in the course of his lecture, stated that the heat in the center of the earth is due to deposits of radium, for the deeper you dig the more radium is obtained.

Prof. Rutherford was the first person to measure the mass and velocity of the electrons of radium. He announced the probability of radium being contained in all matter.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

A joint meeting of the American Society of Mechanical Engineers and the Institution of Mechanical Engineers, of Great Britain, will be held in Chicago May 31 to June 3. The headquarters will be at the Auditorium Hotel.

The daily papers are publishing the news that "Nikola Tesla and Prof. M. I. Pupin are jointly working on an invention, which, if successful, will go far toward putting an end forever to warfare. They are, it is said, planning nothing short of a wireless percussion for setting off explosives from a distance."

The General Electric Company is negotiating for an outfit whereby it can communicate between its plants at Schenectady, N. Y., and Lynn, Mass., by means of wireless telegraphy.

Mr. William Marconi, who arrived in New York a week ago after a succesful experiment in talking by wireless telegraphy to both sides of the Atlantic from mid-ocean, sailed Saturday to do more experimenting in Europe on his apparatus. He said that his efforts will be confined to working on an instrument by means of which rapid transmission can be obtained. "At present," he said, "we can send but 30 words a minute. That is a great drawback, and I shall keep at the work until I get something with which I can talk at the rate of ordinary telegraph instruments."

Many thousands of dollars are being invested in electrical machinery for mining coal in Colorado. When electricity is installed fewer men are required to operate the mine and a larger quantity of coal can be hoisted.

Some experiments to determine the influence of radium on the electric spark have recently been made by Prof. A. Stefanini and Dr. L. Magri. According to *Nature* the following results were noted: For discharges between two spheres, or between a positively charged point or sphere and negative disk, the discharge is facilitated by radium for short speaking distances and impeded for longer ones. If the disk is positive and the sphere or point negative, the discharge is impeded at small sparking distances within a limited interval; in general the effect is nil. For certain sparking distances between a sphere and disk it is possible for radium to impede or facilitate discharge according to which electrode is positive.

Several important contributions have been made recently to the fund which is being raised by the American Institute of Electrical Engineers as its share of the expense in securing the ground on which the new engineering building is to be erected in New York. Mr. E. W. Rice, of Schenectady, has contributed $1,000; Mr. Thomas A. Edison, $5,000, and Dr. M. I. Pupin, $5,000. This brings the total fund up to $60,000 at the present time.

A fleet of turbine-driven steamships is to be placed on the Great Lakes by British capital at once. They will make the round trip from Toronto to Port Arthur or Duluth in eight days. The ships will carry 250 passengers and will run at a sustained speed of 16 miles an hour.

Prof. Michael I. Pupin, Ph.D., of Columbia University, recently lectured on "Electric Resonance," before the Department of Electricity, Brooklyn Institute, and said that the subject of electrical resonance had acquired additional impulse in the past eight years, because of its connection with electrical signaling. He recommended students to make first a study of mechanical phenomena of matter in motion, and illustrated his talk by causing oscillation in a steel rod that was fastened to the end of a table. This problem of oscillation was explained, and by the aid of various instruments, run by an electrical machine in the small gallery, it was shown how the principle is carried out to its fulfillment in wireless telegraphy.

Charles T. Yerkes, who arrived from England last week, in speaking about his London underground railway system, said: "The lines in the Metropolitan district, which is the key to our entire system, will be ready for operation by January 1. Our power house is already finished, and the equipment is being supplied as rapidly as possible. The lines of the Metropolitan district have been in operation for 30 years, but the road has always been run by steam. To show what the British investing public think of our stock, I have only to say that it has advanced from 25 to over 40, while consols have, in the meantime, declined from par to under 90."

NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION.

The following is the programme for the three days' session of the Twenty-seventh Convention of the National Electric Light Association now being held in Boston:

Tuesday, May 24

MORNING SESSION.

Address, President Charles L. Edgar.

Report of Committee on Progress, by Mr. T. Commerford Martin.

"A Three-Wire, 500-Volt Lighting System," by Mr. Walter I. Barnes.

"Luminous or Flaming Arc," by Mr. Welles E. Holmes.

Report of Committee on Standard Candle Power of Incandescent Lamps, by Dr. Louis Bell, chairman.

Report of Committee on Legislative Policy, by Mr. Samuel Insull, chairman.

Report of Committee on Photometric

CHARLES L. EDGAR,
President National Electric Light Association.

Values of Arc Lamps, by Mr. Henry L. Doherty, chairman.

Report of Committee on Uniform Accounting, by Mr. Guy L. Tripp, chairman.

AFTERNOON SESSION.

"A One-Hundred-Mile Transmission Line," by Mr. Robert Howes.

"Grounding the Neutral of High Voltage Generators," by Mr. George N. Eastman.

"Remote Control of Electrical Apparatus," by Mr. William H. Cole.

"The Organization and Equipment of an Arc-Lamp Department," by Mr. Samuel G. Rhodes.

"Electric Heating," by Mr. James I. Ayer.

"Lost and Unaccounted for Current," by Mr. C. W. Humphrey.

Wednesday, May 25

MORNING SESSION.

"Economy in Minor Station Supplies," by Mr. Edgar B. Greene.

"Notes on the Internal-Combustion Engine as Applied to Central Station Service," by Mr. E. E. Arnold.

"Economy Test of a 5,500 Horse-power, Three-Cylinder, Compound Engine and Generator," by Messrs. J. D. Andrew and W. F. Wells.

"The Mechanical Stoker and the Human Operator," by Mr. Edwin Yawger.

Report of Committee on Award of Doherty Gold Medal, by Dr. Schuyler S. Wheeler, Chairman.

Report of Committee on Investigation of Steam Turbines, by Mr. W. C. L. Eglin, chairman.

"Practical Notes on Steam Turbines," by Mr. Francis Hodgkinson.

Thursday, May 26.

MORNING SESSION.

"Electric Light and Power Plants in Connection with Ice Plants," by Mr. C. L. Wakefield.

Report of Committee on Sign and Decorative Lighting, by Mr. Arthur Williams.

Report on Advertising, by Mr. La Rue Vredenburgh.

Report of Committee on Purchased Electric Power in Factories, by Mr. W. H. Atkins, chairman.

Report of Committee on District Heating, by Mr. E. F. McCabe, chairman.

Report on Office Methods and Accounting, by Mr. Frank W. Frueauff.

AFTERNOON SESSION.

"A Proposed System of Standard Instruments for Operating Companies," by Mr. H. P. Davis.

"Single-Phase Power Motors for Electric Lighting Stations," by Mr. W. A. Layman.

Report of Committee on Analysis of Flue Gases, by Mr. Henry L. Doherty chairman.

Wrinkles, Mr. Charles H. Williams, editor.

Question Box, Mr. H. T. Hartman, editor.

EVENING SESSION.

"Types of Large Water Power Installations," with stereopticon, by Dr. F. A. C. Perrine.

Executive session.

KUBEL HYDRO-ELECTRIC POWER HOUSE AND AUXILIARY STEAM PLANT.

BY FRANK C. PERKINS.

Some of the largest hydro-electric plants in Europe find it necessary to install auxiliary steam equipments for helping out during time of low water. A reserve steam plant of 1,000 hp. capacity has been provided at the Elektricitats Werk Kubel, supplying current for from 30 to 50 days when the water power is not sufficient to take care of the existing load. The Kubel hydro-electric plant shown in the accompanying illustrations, Figs. 1 and 2,

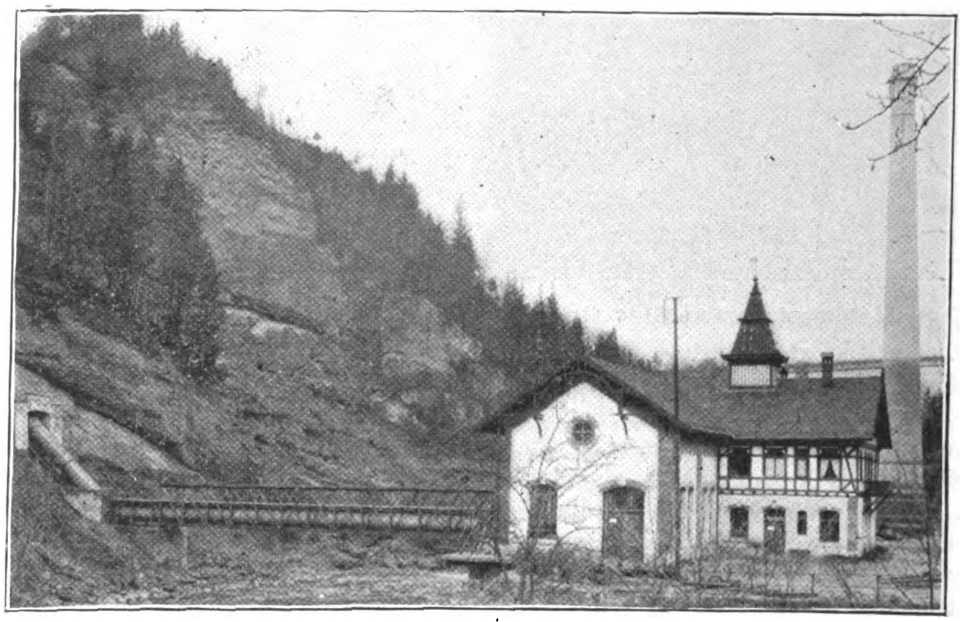

Fig. 1.—Kubel Hydro-Electric Plant

is supplied with water by a steel pipe 294 meters in length, a portion of which is seen in the illustration of the exterior of the power house. The dam is 104 meters long, the thickness at the top being 3 meters and at the base 45 meters. The profile of the hydraulic installation is shown in Fig. 3, while Figs. 4 and 5 show the plan and elevation of the power house.

The hydraulic plant includes four turbine sets of 500 hp. each, and two turbine sets of 1,000 hp. each, while the auxiliary steam plant consists of one vertical compound engine of 1,000 hp. capacity directly coupled to an 850 kw. dynamo operating at a speed of 150 revolutions per minute. The steam engine and the hydraulic turbine were installed by Escher, Wyss & Co. of Zurich, Switzerland, while the electrical equipment

was supplied by the Elektricitats-Actien-Gesellschaft, formerly W. Lahmeyer &

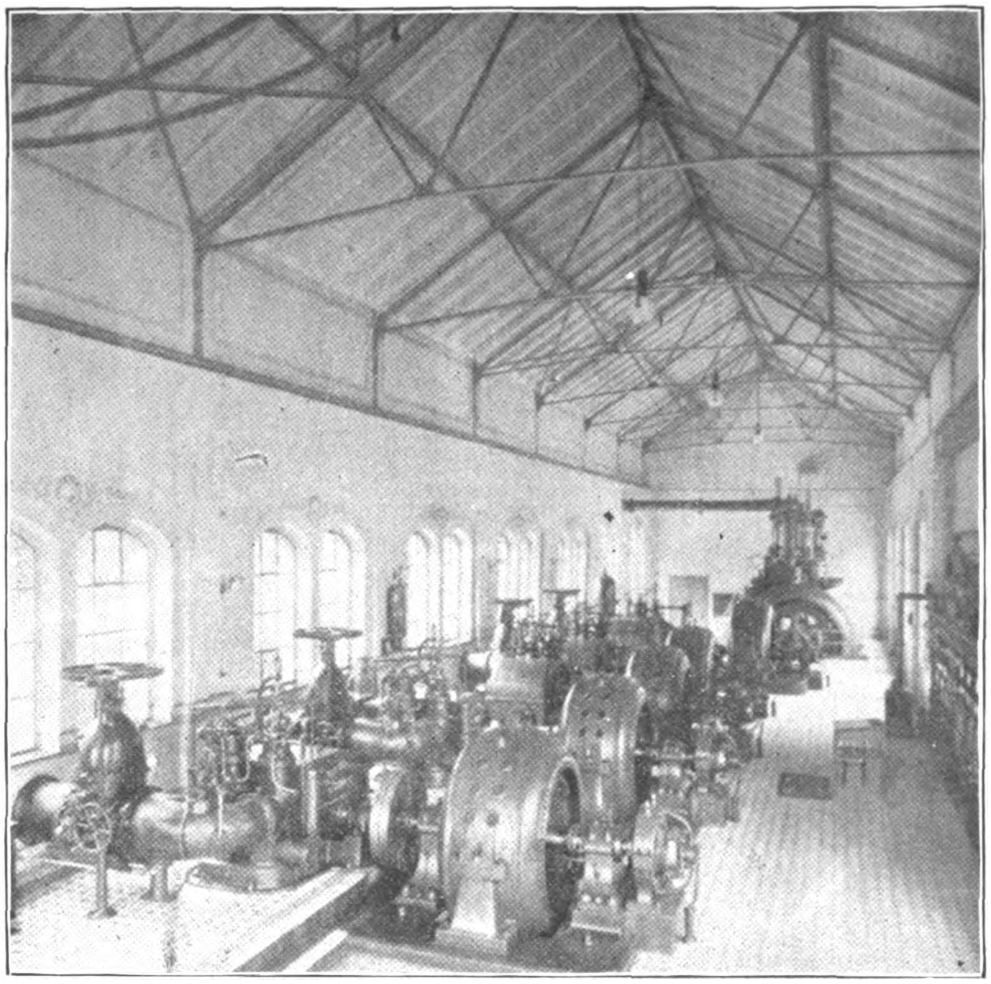

Fig. 2.--Kubel Hydro-Electric Power House and Auxiliary Steam Plant.

Co. of Frankfort, Germany. The 500 hp. hydraulic turbines operate at a speed of 375 revolutions per minute, and are directly coupled to 400 kw. alternators which supply a three-phase current of 10,100 volts directly in the windings of the generator. These machines are of a revolving field type having 16 poles. The outside diameter of the armature is 1,900 mm., while the inside diameter is 1,500 mm., the width being 400 mm. including the ventilating device, while there are in all 96 slots for the winding.

The 1,000 hp. hydraulic turbines are directly coupled to two 850 kw. three-phase machines having 20 poles and operating at a speed of 300 revolutions per minute. One of these machines may be noted in the background in Fig. 2, just in front of the steam driven unit, while the four machines in the foreground are of 500 hp. each. The 850 kw. machine has 120 slots in the armature, the width being 420 mm. and the inner diameter 2,200 mm. while the outer diameter measures 2,670 mm.

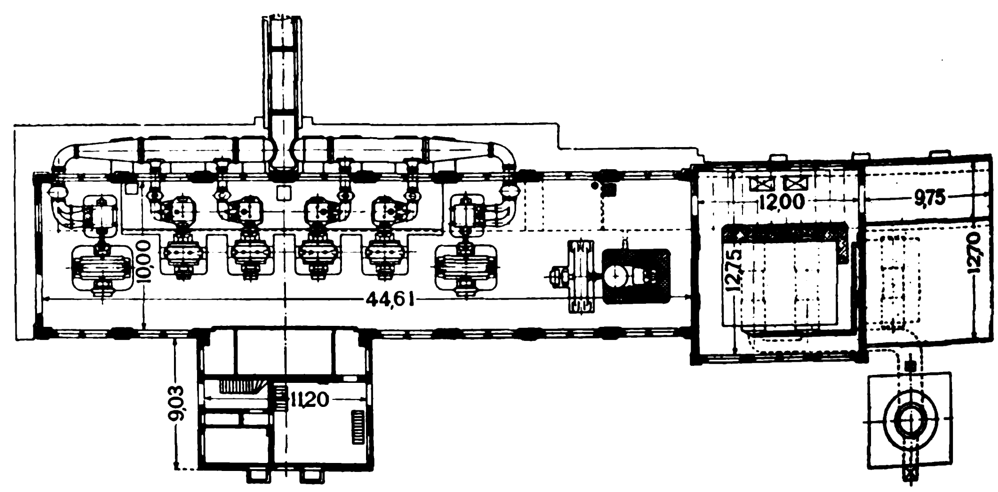

Fig. 4.—Plan of Kubel Power Plant.

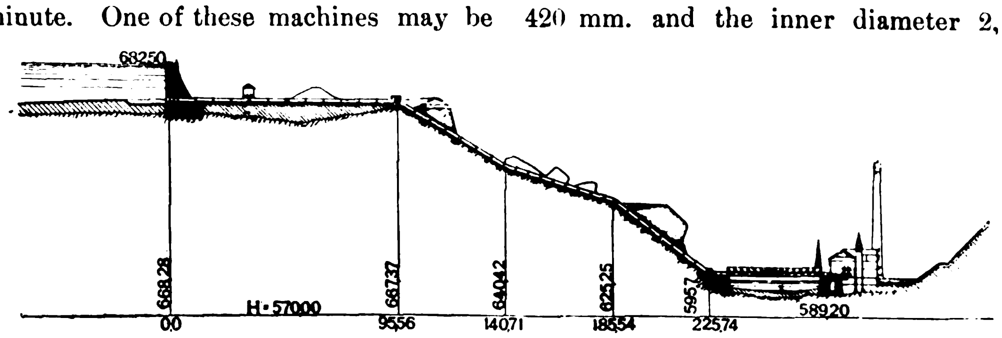

Fig. 3.—Profile of Hydraulic Installation at Kubel Hydro-Electric Plant.

The vertical compound engine has a stroke of 750 mm., the high pressure cylinder having a diameter of 685 mm. and the low pressure cylinder 1,150 mm. It operates at a speed of 150 revolutions per minute and is supplied with superheated steam at 280 degrees. The boiler plant includes two water tube boilers each having a heating surface 270 square meters, and each provided with a superheater of 65 square meters heating surface. The boilers operate at a steam pressure of 10 atmospheres and measure 1.4 meters in diameter and 6.8 meters in length. They are provided with 171 tubes each having an outer diameter of 95 mm. and a length of 5.06 meters. The engine is directly coupled to the revolving flywheel field magnet of the 850 kw. alternator which has 40 poles. The armature has 240 slots and is 330 mm. wide. The inner diameter of the armature is 3.2 meters and the outer diameter is 3.6 meters, while the total outside measurement of the generator is 4,200 mm. The exciter for this unit is a multipolar direct current dynamo mounted on the outside of the main bearing of the alternator.

The current is transmitted by overhead lines at a pressure of 10,000 volts and is transformed at the sub-station to 550 volts for the secondary power circuit and to 125 volts for the lighting distribution. The current is sold for power purposes at the rate of 400 francs per horse power per year for a small machine, 275 francs per horse power per year for machines of 10 hp. capacity, and at 180 francs per year for motors of 50 hp. or over.

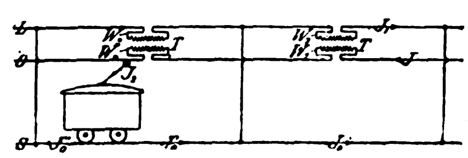
Heligoland's Lighthouse Searchlight.

The searchlight in the lighthouse tower at Heligoland, which was referred to some time ago in these columns, is of a novel type, according to the *Model Engineer and Electrician*. The lamp consists of three arc lights, reflecting mirrors, and projector regulating devices 120 degrees

apart, all operated automatically. Thus three beams of light are thrown simultaneously from the top of the tower.

EARTHED RETURNS FOR ALTERNATE CURRENT RAILWAY WORKING.

In a contribution to the *Elektrotechnishe Zeitschrift*, Dr. Behn-Eschenburg discusses the fall of potential in earthed rail returns when alternating currents are employed, and the means available for reducing this leakage, or its effect upon telegraphs and telephones using earth returns. A remedy which at once suggests itself consists in the choice of a periodicity for the current by which the instruments are not influenced. The effect of the self-induction of the track rails increases the loss for higher periodicities with the same current. It would, therefore, seem advantageous to reduce the periodicity to a minimum. At the same time it is well known that the human ear is not susceptible to the vibrations set up by low periodicities, so that disturbance as far as the telephone is concerned could be easily avoided. On the other hand, the relays used for the telegraphs, signal bells, and telephones on railways are especially sensitive to these low periodicities, and consequently liable to be affected by the same. The human ear is capable of detecting vibrations from about 16 to 16,000 periods per second. The mean periodicity of the vibrations produced by the voice is about 400, while the alternating currents in vogue employ periodicities of from 16 to 60. The vibrations due to the commutator segments of direct current machines used for working tramways range from 500 to 1,000 per second. To the fact that these vibrations approximate in number those produced in speaking, is due the comparatively marked disturbance of telephone apparatus by tramways worked with direct current. The author goes on to describe in detail some experiments carried on in the laboratory attached to the Maschinenfabrik Oerlikon in order to determine the effect of different periodicities on different telegraph and telephone apparatus. He then proceeds to deal with the practical means available for preventing leakage from earthed returns. One of these consists in the system introduced by the Maschinenfabrik Oerlikon, whereby the current in the track rails is transferred to an auxiliary conductor, the track rails in fact only carrying the return current over a short section upon which the moving train happens to be, being for the rest conveyed by the auxiliary conductor. The advantages offered by such an arrangement over an insulated return may be called into question. A decisive answer is found in the simplification enabled by the use of the wheels of the train as collectors. The arrangement is shown diagrammatically



herewith. Parallel to the track rails, S, in which the fall of potential is to be compensated, an auxiliary conductor, L, is provided electrically bonded at intervals with the track rails. By means of these connections the track rails and auxiliary returns are divided into a number of linked sections. In certain of the sections of the auxiliary conductor the secondary windings, W_2, of ordinary transformers are placed, whose primary windings, W_1, are connected in series with the overhead conductor, O. Several possible modifications of this arrangement are referred to by the author, who also enters into the theory of its working, showing the ratio which should exist between the dimensions of the windings, W_1 and W_2. He points out, incidentally, that a transformer should be used whose self-induction is very high compared with the non-inductive resistance of a section of the auxiliary return, and that an EMF. must be generated by this transformer equal to the fall of potential over the section. The total loss of pressure in the overhead conductor is thereby increased by the amount lost in the auxiliary return. In conclusion, the author gives the results of some careful experiments with the system, showing that a reduction in proportion to the total current of $\frac{4}{100}$ can be made in the current conveyed by the track rails. That is to say the current in the track rail can be reduced to one twenty-fifth of the total. This device is not unlike, in principle, the negative boosters used in the return current feeders of direct current lines.—*Electrical Engineer, London.*

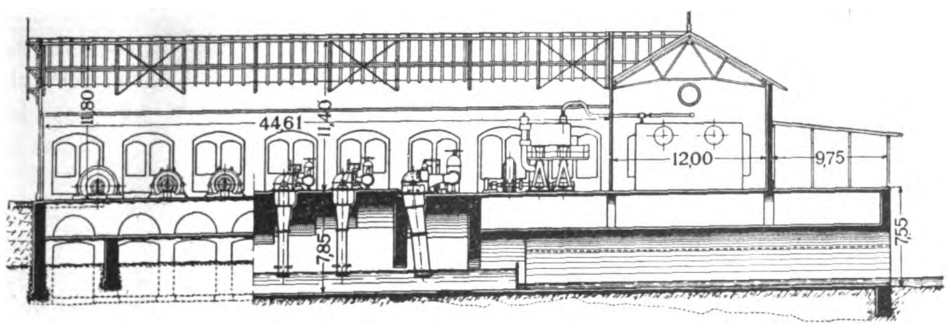


Fig. 5.—Elevation of Kubel Hydro-Electric Power House.

SAFE PRESSURES FOR STEAM BOILERS.

ARTICLE II.

BY W. H. WAKEMAN.

In order to make a series of articles on this subject complete it is necessary to explain the terms used, so that readers may fully comprehend their meaning and application.

The tensile strength of a boiler plate means the number of pounds or tons that is required to pull a bar 1 inch square, made of this plate, into two pieces. This is not altogether a theoretical calculation, but is the result of a test made on a piece of the plate in question. It is not practical to take a bar of this metal 1 inch square, for this test, therefore a much smaller piece is taken and tested, then from the total pull required, and the sectional area where fracture occurred, it is possible to tell the stress required to part a bar one inch square.

For illustration suppose that a piece of

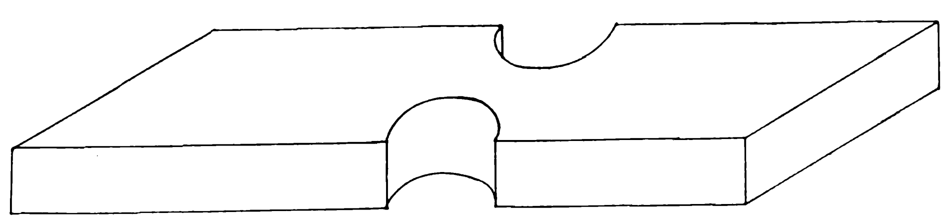

Fig. 1.

plate ½ inch thick is taken and reduced in section as shown in Fig. 1 until it is ½ inch wide at the smaller part. The sectional area at this point is $.5 \times .5 = .25$ square inch. Suppose that it parted under a stress of 15,000 pounds. This is to be multiplied by a number obtained by dividing 1 by the area of test piece. Then $1 \div .25 = 4$ and $15,000 \times 4 = 60,000$

pounds, which is the tensile strength of the plate in this case.

English rules and formulas sometimes state the tensile strength in tons. If it is desired to apply these to a case where the strength is given in pounds, divide by

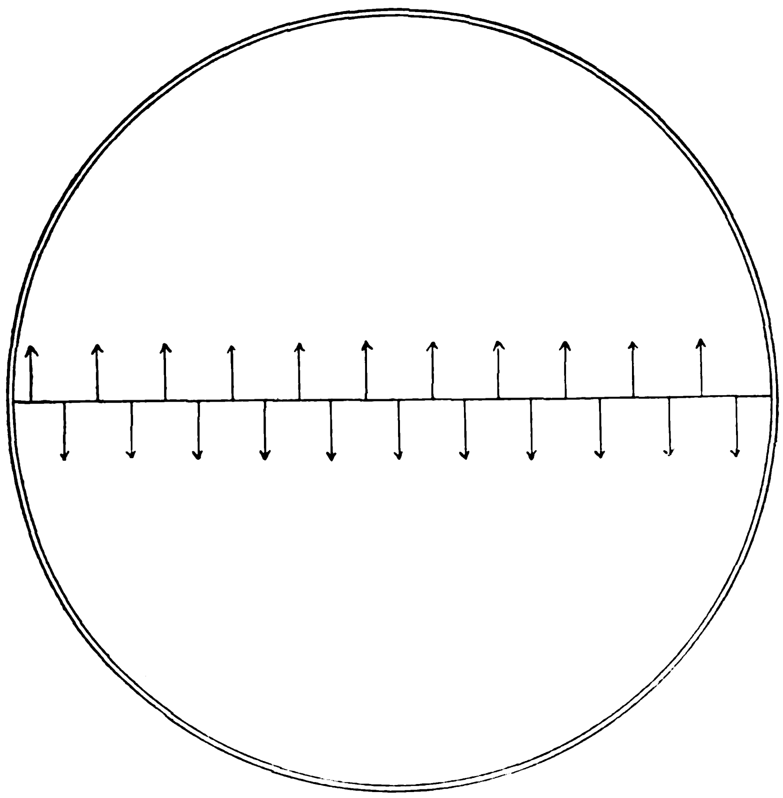

Fig. 2.

2,240 and the quotient is in tons. This is mentioned in order to prevent confusion in regard to the kind of ton that is meant.

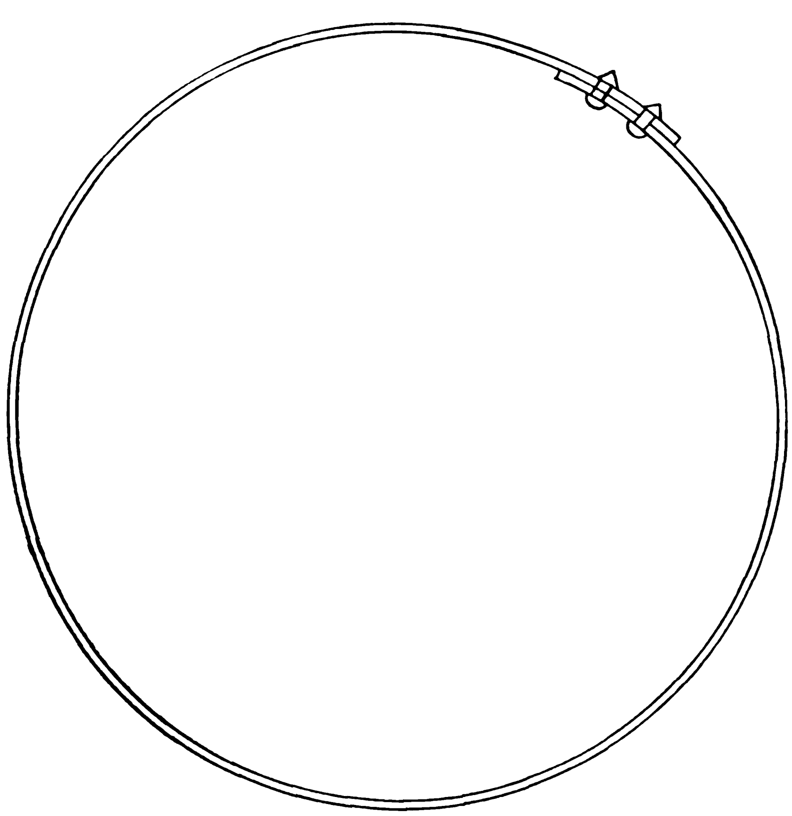

Fig. 3.

In the above case it is 60,000 ÷ 2,240 = 26.78 tons.

If the plate is to be located so that the greater strain will come lengthwise of the grain, then the test piece should be tested in that way, but where the strain is to come across the grain, care should be taken to have the test piece fairly represent this condition. This is important because in the latter case the tensile strength is less than in the former. Where the shell of a tubular boiler is made in two plates, the grain lies lengthwise of the boiler, hence the greater strain is applied across the grain, and this is one objection to the two plate boiler. The thickness of plate is a factor because plates for stationary boilers are usually much less than 1 inch thick, therefore the thickness in decimals of an inch accounts for the material to be depended

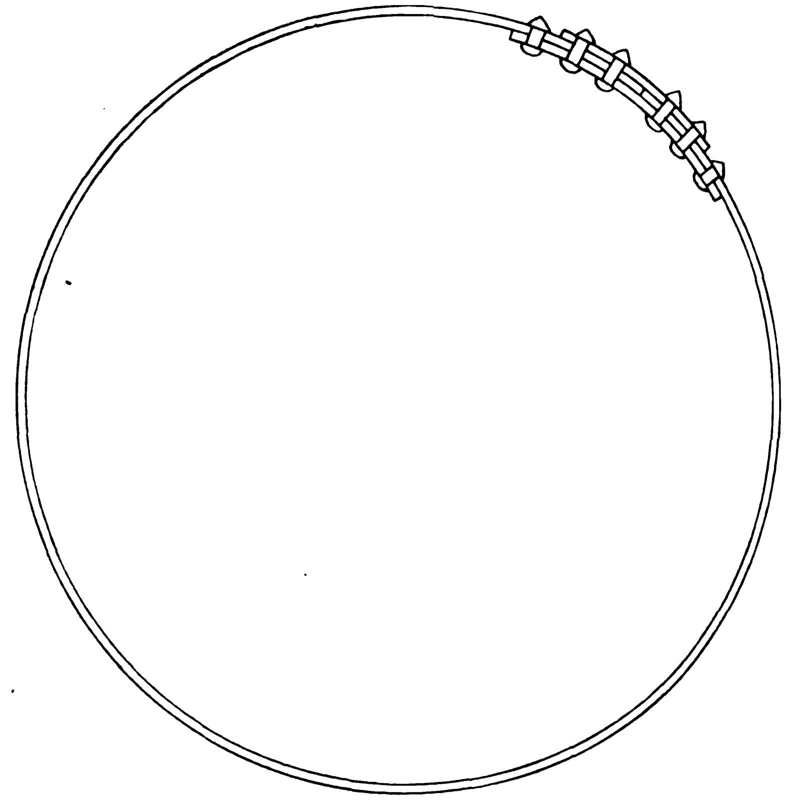

Fig. 4.

upon. When the strength of a boiler shell is calculated, a strip 1 inch wide is assumed to represent conditions which apply to the whole, but this is not mentioned in the formulas because multiplying by 1 does not change the value of a factor. The strength of riveted joint, stated as a decimal fraction, is used because such a joint in always weaker than the solid plate. This of course operates to reduce the actual strength, as a structure of any kind is no stronger than its weaker part. It is taken into account in every rule or formula given for determining the safe pressure, but it is not always stated in the same way, hence the real fact is sometimes overlooked by readers who do not study the subject.

As I have fully explained and illustrated the comparative strength of riveted joints of many kinds in previous issues of this paper, no extended notice of the subject is required here, but brief reference to it is proper.

The circle in Fig. 2 represents a ring of solid plate. If plates could be welded so as to be equally strong at every point, it would eliminate this factor, or, in other words, the fraction would be raised to 1, thus having no effect on the remainder of the calculation, but this is not practical in the present state of the art.

Fig. 3 represents a plate containing a

double riveted joint of ordinary design, which has about .70 of the strength of Fig. 2. Fig. 4 shows a ring from a plate containing a superior form of joint which has about .90 of the strength of Fig. 2.

The diameter of boiler is taken into account because pressure acts at right angles to a line drawn through the larger part of shell at a given point. This is illustrated in Fig. 2. It is true that pressure acts on every part of the circumference, but only the diameter is used, for this when multiplied by the pressure per square inch gives the strain on the two sides of shell at both ends of the straight line in Fig. 2. Some rules take the whole diameter and both sides of the shell, while others only take the radius or one-half the diameter and one side of the shell, but the result is the same.

The factor of safety is fully explained in the preceding chapter. Briefly stated it represents the proportion of estimated ultimate strength of shell that it is safe to depend on in every day practice. It is the only factor in the calculation that is left to the judgment of the calculator, for although it is arbitrarily stated in some cases, and given with many modifications in others, there is nothing to prevent the substitution of any other that may seem advisable.

A NEW PORTABLE CAPILLARY ELECTROMETER.

BY L. RAMAKERS.

Mr. S. W. Y. Smith, M. A., demonstrator in physics, Royal College of Science, London, recently presented to the Physical Society of London a new portable capillary electrometer, the principal advantages of which over other types existing, are as follows: The liability to get out of order is reduced to a minimum; the liquids being completely inclosed, the instrument can be carried about freely, evaporation of the elecrolyte is prevented and adjustments to different degrees of sensitiveness are made very easily. The pneumatic key, free from appreciable thermoelectric effects, and requiring no attention, greatly facilitates the observation of minute electromotive forces by means of the capillary electrometer; keys of the kind described can be used in measurements in which the electrometer is not employed and form convenient commutators, make-and-break keys, etc. They can be worked at a distance with certainty, and, engaging very little of the observer's attention, allow almost undivided observation of deflections, etc., arising from changes of contact produced by their means.

The instrument presented by Mr. Smith is a modification of the form of capillary electrometer represented in Fig. 1, and consisting of two wide tubes joined across by a capillary tube which is cylindrical, and may be horizontal or may slope upwards at any angle from b towards a. The apparatus contains mercury and sulphuric acid of about maximum conductivity, distributed roughly as shown. A spring key, like that represented in the figure, is commonly used with the instrument, and keeps the platinum terminals P_1 and P_2 at the same potential unless the lever S is depressed. When the lever is depressed

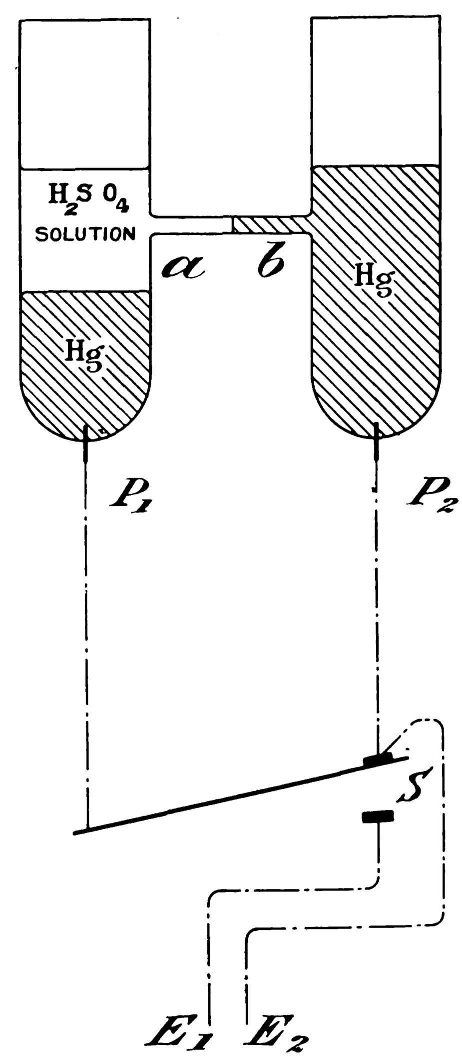

Fig. 1.

the potentials of the terminals become E_1 and E_2, which may, for example, be the potentials of two points in a potentiometer circuit. It is the function of the instrument to determine whether these potentials are the same or different.

The nature of the modifications made in the present electrometer is shown in Fig. 2. To prevent evaporation of the sulphuric acid solution, without preventing free motion of the liquids within the apparatus, the wide tubes are closed at the top, but are joined across by another tube opening into them as shown. With this arrangement the apparatus is made air tight, and can, if desired, be made air free by exhaustion of the apparatus before sealing. The apparatus contains approximately enough mercury to completely fill one limb, and about half as much sulphuric acid solution. By suitably adjusting the distribution of the mercury and the solution in the two limbs, the apparatus can be arranged for use with the capillary tube either horzional or tilted upwards at a considerable angle.

The distribution of the mercury can be altered most easily by means of a crosspiece provided with a top as represented in Fig. 2 by dotted lines. When the top is open there is free communication between the mercury in the two limbs, and the relative amount in each can be altered by tilting the apparatus. When the top is closed the two quantities of mercury are insulated from each other.

The usual spring key has several disadvantages. Thus, if it is made of brass, the contacts frequently become unsatisfactory through surface tarnishing, and if, to avoid this, the bearing surfaces are made of platinum, the key sometimes shows pronounced thermoelectric effects. Further (and this is a point of some importance in a portable instrument), the key cannot conveniently be fastened on to the same stand as the rest of the instrument, for, unless the stand and the support on which it rests are very rigid, the pressure necessary to depress the spring produces sufficient movement of the meniscus, by change in the inclination of the capillary tube during the act of depression, to render the detection of minute changes of surface-tension impossible.

The mercury key, represented in Fig. 2, is free from these disadvantages. It consists, as shown, of a U-tube closed at one end and communicating at the other with a pneumatic-pressure ball and containing mercury in the bend. Three platinum wires are fused into the tube and connected as shown. It is obvious that the same change of contacts is produced by squeezing the ball B, as by depressing the lever S in the spring key. The mercury in this key takes the place of the lever in the spring key, and the two different contacts between it and E_1 and E_2 respectively are here quite definite and practically independent of the amount of pressure exerted upon the ball B. Further, the contacts are not exposed directly to the laboratory atmosphere. The thermoelectric effects are very small since the changing contacts take place between platinum and mercury which are almost identical thermoelectrically. The warmth

communicated to the key from the hand of the operator can be neglected, and the heat produced by the compression of the air in the key need only be very small. The key can be fixed to the same stand as the rest of the apparatus, for even if the pressure which changes the contacts is applied as suddenly as possible the maximum vertical pressure upon the stand is only a few grams, whereas in the case of the spring key it may be 500 grams or more.

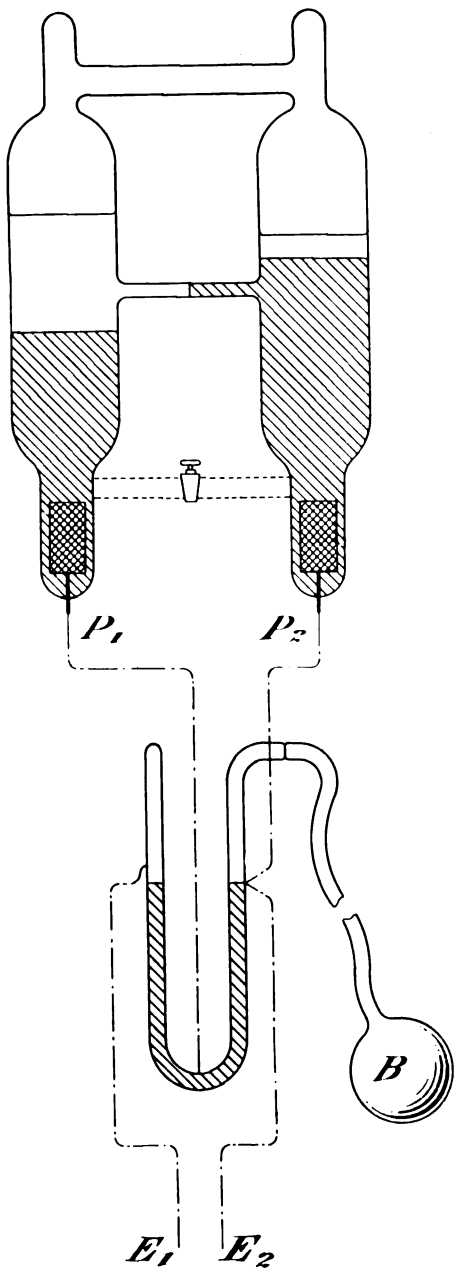

Fig. 2.

By adjusting the length of the mercury column in the key so that it is only slightly less than the length of the U-tube between the two extreme platinum wires, the change of potential at P_1 from E_2 to E_1 and conversely, can be made almost instantaneously. Hence measurements can be made with the instrument even if the zero is altering fairly rapidly. With a key of this kind it is also obvious that the observation of the meniscus through the microscope can receive a very near approach to undivided attention.

Commutators and keys which make a set of connections in a prescribed order can be constructed on the same principle as the pneumatic key described. Fig. 3 represents a combined commutator and electrometer key.

The U-tube to the left is the key already described, and the double U-tube to the right is the commutator. The positions of the different wires are so arranged with request to the levels of the mercury that it requires greater pressure to change the contacts in the double U-tube, than in the tube to the left. The first effect of pressure is to throw the electrometer into the potentiometer or other circuit. connecting P_1 with E_1 and P_2 with E_2. On increasing the pressure, the connections

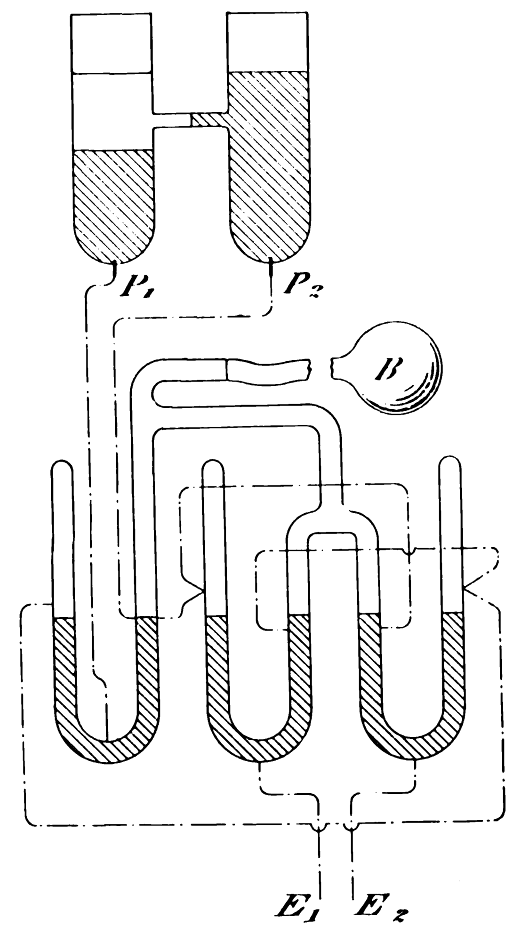

Fig. 3.

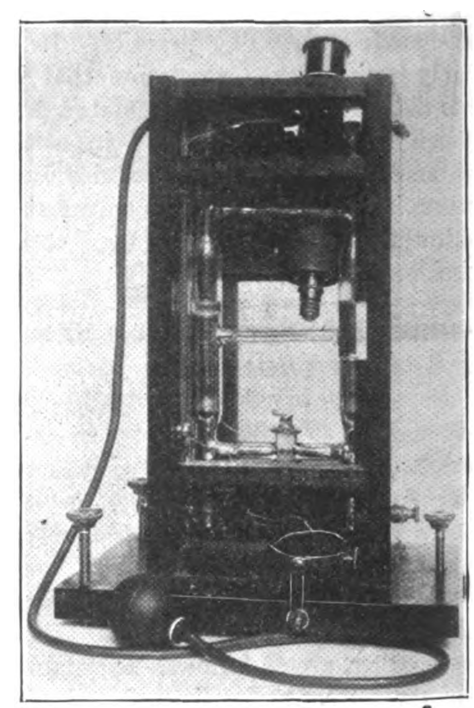
in the double U-tube are reversed and P_1 is connected with E_2 and P_2 with E_1. Hence, when the contacts change in the commutator, we get a motion of the electrometer meniscus corresponding to approximately twice the difference of potential between E_1 and E_2, and so, in this way, the sensitiveness of the instrument is doubled.

The sensitiveness of the electrometer, using the simple key first described, is such that when the diameter of the wide tubes is about 1 cm. and the diameter of the capillary is about 1 mm., a movement of the meniscus perceptible with certainty in a microscope magnifying 100 times is produced by a potential difference equal to 0.0001 volt. The actual extent of the movement is somewhat variable, and amounts usually to about 0.01 mm.

The sensitiveness of 0.0001 volt, which is obtainable without any difficulty if the mercury is clean, is sufficient for a great many measurements in which the electrometer can be employed, and for these the electrometer (which for the purpose in question is really a surface-tension galvanometer) is more convenient than an ordinary galvanometer with a suspended magnetic system. The electrometer is much more easily set up than an ordinary galvanometer. There is no suspension, no lamp and scale, and, practically, no leveling; but it is advisable when working with the instrument that the potential of E_1 should never be more than a few tenths of a volt less, or more than about



A New Portable Capillary Electrometer.

a volt greater, than the potential of E_2. These conditions of working are, in general, not difficult to satisfy. If the potential-differences applied exceed either of the limits previously mentioned, it is sometimes necessary to run some of the mercury through the capillary tube in order to get the instrument again into its best working order.

The accompanying photograph represents one form of the instrument described. The arrangement of the different parts will be obvious from the description already given. The illumination of the end of the mercury thread is effected by means of a concave mirror attached to the base of the instrument.

THE STEAM TURBINE AS APPLIED TO ELECTRICAL ENGINEERING.*

BY THE HON. CHARLES A. PARSONS, F.R.S.; G. GERALD STONEY AND C. P. MARTIN.

In the early days of electric lighting the speed of dynamos was far above that of the engines which drove them, and therefore belts and other forms of gearing had to be resorted to. To make a high-speed engine, therefore, was of considerable importance, and this led to the possibilities of the steam turbine being considered. It was, however, at once seen that the speed of any single turbine wheel driven by steam would be excessive without gearing, and in order to obtain direct driving it was necessary to adopt the compound form, in which there were a number of turbines in series, and thus, the steam being expanded by small increments, the velocity of rotation was reduced to moderate limits. Even then, for the small sizes of dynamos at that time in use, the speed of revolutions was high, and therefore a special dynamo had to be designed. Speaking generally, an increase of speed of a dynamo increases its output, and therefore it was obvious that such a high speed dynamo would be very economical of material.

These considerations led in 1884 to the first compound steam turbine being constructed. It was of about 10 hp. and ran at 18,000 revolutions per minute, the diameter of the armature being about 3 inches. This machine, which worked quite satisfactorily for some years, is now in the South Kensington Museum.

Before, however, this first turbo dynamo was constructed, a set of preliminary experiments were commenced with the view of ascertaining, by actual trial, the conditions of working equilibrium and steady motion of shafts and bearings at the very high speeds of rotation that appeared to be essential to the construction of an economical steam turbine of moderate size. Trial shafts were run in bearings of different descriptions up to speeds of 40,000 revolutions per minute; these shafts were 1½ inches in diameter and 2 feet long, the bearings being about ⅜ inch in diameter. No difficulty was experienced in attaining this immense speed, provided that the bearings were designed to have a certain small amount of "give" or elasticity, and after the trial of many devices to secure these conditions, it was found that elasticity combined with frictional resistance to transverse motion of the bearing bush, gave the best results, and tended to damp out vibrations in the revolving spindle. This result was achieved by a simple arrangement; the bearings in which the shaft revolved was a plain gun-metal bush with a collar at one end and a nut at the other; on this bush were threaded thin washers, each being alternately larger and smaller than its neighbor, the small series fitting the bush and the larger series fitting the hole in the bearing block, these washers occupying the greater part of the length of the bush. Lastly, a wide washer fitted both the bush and block, forming a fulcrum on which the bush rested, while a spiral spring between the washer and the nut on the bush pressed all the washers tightly against their neighbors. It will be seen now that, should the rotating shaft be slightly out of true (which it is impossible to avoid in practice), the effect is to cause a slight lateral displacement of the bearing bush, which is resisted by the mutual sliding friction of each washer against its neighbor. The shaft itself being slightly elastic, tends to center itself upon the fulcrum washer before mentioned; and under the gyrostatic forces brought into play by the rapid revolutions of the shaft and influenced by the frictional resistance of the washers, the shaft tends to assume a steady state of revolution about its principal axis, or the axis of the mass, without wobbling or vibration. This form of bearing was exclusively used for some years in turbine engines aggregating some thousands of horse power, but it has since been replaced by a simpler form fulfilling the same functions. In this latter form the gun-metal bush is surrounded by several concentric tubes fitting easily within each other with a very slight lateral play; in the interstices between the tubes the oil enters, and its large viscosity when spread into thin films has the result of producing great frictional resistance to a rapid lateral displacement of the bearing bush; the oil film has also a centring action, and tends, under vibration, to assume a uniformity of thickness around the axis, thus centring the shaft, and, like a cushion, damping out vibrations arising from errors of balance. This form of bearing has been found to be very durable and quite satisfactory under all conditions.

These first turbine engines consisted of two groups of 15 successive turbine wheels, or rows of blades, on one drum or shaft within a concentric case on the right or left of the steam inlet, the moving blades or vanes being in circumferential rows projecting outwardly from the shaft and nearly touching the case, and the fixed or guide blades being similarly formed and projecting inwardly from the case and nearly touching the shaft. A series of turbine wheels on one shaft were thus constituted, and each one complete in itself is like a parallel flow water turbine; the steam, after performing its work in each turbine, passing on to the next, and preserving its longitudinal velocity without shock, gradually falling in pressure as it passes through each row of blades, and gradually expanding. Each successive row of blades was slightly larger in passage way than the preceding to allow for the increasing bulk of the elastic steam, and thus its velocity of flow was regulated so as to operate with the greatest degree of efficiency on each turbine of the series.

About 1890, however, an account of the temporary loss of control of the patents, the radial flow type of turbine was reluctantly adopted, and this was in 1892 arranged to work condensing, and a 100 kw. plant driving a 2,000 volt single-phase alternator at 80 periods, which ran at 4,800 revolutions per minute and therefore was two-pole, when tested by Prof. Ewing was found to take only 27 lbs. per kilowatt-hour, with 100 lbs. steam pressure moderately superheated to about 70 degrees F. and with 27 inches vacuum, a result comparable with the best obtained by reciprocating engines at that time, and thus a wide field was opened up for the use of the steam turbine as a prime mover. Many of these plants, mostly of 150 kw., were made for electric lighting stations.

In 1894, on the recovery of the original patents, the parallel flow type was reverted to, with considerable improvements in design calculated both to increase the economy and decrease the cost of manufacture. Instead of the steam entering at the center and expanding both ways, one set of blades was replaced by a set of dummy pistons which were substituted for them, in which a grooved piston or dummy on the spindle ran close to but not in contact with corresponding grooves in the cylinder, thus making a practically steam-tight and yet frictionless joint. The bearings also were made of the later type, with several concentric tubes. At the same time the system of blading was greatly improved, giving a more perfect form of blade, and one also with much greater mechanical strength than in the original formation.

A good vacuum is of great importance in a turbine, as the expansion can be carried in the turbine right down to the vacuum of the condenser, a function which is practically impossible in the case of a reciprocating engine, on account of the excessive size of the low-pressure

*Abstract of paper presented before the British Institution of Electrical Engineers, May 12, 1904.

cylinder and also of the ports, passages and valves which would be required. Thus in a turbine the benefit derived from a good vacuum is much more than in a reciprocating engine, every 1 inch of vacuum between 23 inches and 28 inches affecting the consumption on an average about 3 per cent. in a 100 kw., 4 per cent. in a 500 kw., and 5 per cent. in a 1,500 kw., the effect being more at high vacua and less at low. It is thus seen how a good vacuum is of importance in a turbine plant, and in this regard it may be well to look into the conditions necessary for obtaining the same. The first point is to avoid all air leaks, and this is easily accomplished in a turbine plant, as there are no packed glands and stuffing boxes to leak. The only places where leakage of air is possible are where the turbine spindle comes out of the cylinder, and here leakage of air is rendered very small by packing the glands with steam, so that any leakage which takes place is steam and not air. The next is to have a suitable condenser, and in this regard sufficient area must be allowed by suitable arrangements of the tubes, and also ample way for the steam between them for proper velocities of the water in the tubes, sufficient supply of cooling water and efficient means of cooling the condensed water so as to keep the air-pump cool, and full provision for extracting by the air-pump and other means the inevitable small quantity of air which must leak in. By attention to these requirements it is unnecessary to increase the size of the condenser beyond that used in ordinary practice, so that in the case of the most recent condensers for steam turbines from 10 to 12 lbs. steam is condensed per square foot per hour; and at this rate of condensation, vacua of from 27½ inches to 28 inches, with barometer 30 inches, can be obtained at full load. The amount of cooling water generally allowed is about 50 times the full-load steam consumption, which will increase the vacuum under normal conditions by about ¾ inch or 1 inch over that obtained by the usual 30 times the steam used. If we allow 14 feet total head on the circulating pump due to lift, and for friction in the pipes and condensers, etc., which in most cases is excessive, especially where the return pipe is sealed, with 50 times the steam consumption in a plant taking 18 lbs. steam per kw. hour, and assuming 50 per cent. efficiency in the pump and motor, the power used by the circulating pump is only 1 per cent., and with circulating water 30 times the steam consumption it would be 0.6 per cent., a difference of only 0.4 per cent., such a small difference as not to be comparable with the gain of 4 per cent. to 5 per cent. in the turbine by the use of increased circulating water.

With regard to extracting the air, a great improvement has been effected by the use of a vacuum augmentor which has been recently introduced. In it the air-pumps are placed about 3 feet below the bottom of the condenser. From any convenient part of the condenser, preferably near the bottom, a pipe is led to an auxiliary condenser, generally about one-twentieth the cooling surface of the main condenser, and in a contracted portion of this pipe a small steam jet is placed which acts in the same way as a steam exhauster, or the jet in the funnel of a locomotive, and sucks nearly all the residual air and vapor from the condenser and delivers it to the air-pumps. A water seal is provided to prevent the air and vapor returning to the condenser. Thus if there is a vacuum of 27½ inches to 28 inches in the condenser, there may be only about 26 inches in the air-pump, which therefore need only be of small size, the jet compressing the air and vapor from the condenser to about half or a little less of its original volume. The small quantity of steam from this steam jet, which is only about 1½ per cent. of that used by the turbine at full load, together with the air extracted, is cooled down and condensed by the auxiliary condenser, which is generally supplied with water in parallel with the main condenser. In this connection it should be observed that condensation in a condenser takes place much more rapidly and effectually if the air is thoroughly extracted than if there is much air present, as the air seems to form a blanket round the tubes and retards the steam getting to them.

In steam turbines the governing is effected either by a centrifugal governor of a well-known type, which keeps the speed constant, or by a core sucked into a solenoid to keep the voltage constant. In most cases, however, the centrifugal is preferable, especially where there are large changes of load, as in traction work, and it is also preferable where alternators have to run in parallel. In either case the governor moves a small relay plunger which regulates the steam, admitted to a relay, which in turn actuates the main admission valve, generally of the balanced double-beat type. The exhaust from the steam relay is utilized for the steam packing the end glands. Thus the governor having only to move the small plunger has very little work to do, and therefore can be made very sensitive. The sensitiveness is still further increased by keeping the whole governor gear in slight movement by connecting one of the pivots of the levers with a cam. These movements are so rapid as not to affect the even turning movement of the turbine. For parallel running of alternators, an even turning movement is of great importance, and this makes the turbine specially suitable for the driving of alternators. It might be thought that there would be difficulty in making alternators driven by reciprocating engines parallel with turbines, and vice versa, but in no case has the running not been satisfactory, and in some the turbines have been found to steady the reciprocating engines.

In the design of dynamos and alternators to be coupled to steam turbines, special regard is to be paid to the large centrifugal force to be encountered. Diameters have to be kept down, and excessive surface speed must also be avoided. Since, then, the diameter has to be small, the length must be increased in proportion and a long core is the result, with moderate diameter, the contrary of slow-speed machines. At the same time, on account of the higher surface speed, the pitch of the poles is greater, thus giving more ampere-turns per pair of poles than is usual. In alternators this gives no trouble at all, as all that has to be provided is sufficiently strong field magnets to overcome the reaction of the armature, and sufficient magnetic resistance to allow of strong field magnets. This extra magnetic resistance can be given either in the air-gap or by saturation of the poles as may be found desirable. These large poles also conduce to diminish magnetic leakage, and as a result very good regulation can be obtained. In low-voltage alternators rotating armatures are preferable, as the iron and copper losses are much less, especially where there are only two or four poles, but rotating armatures, although satisfactory for 500 to 2,000 volts, have not been found suitable for the higher voltages of 6,000 and 10,000 which are now common, and therefore rotating fields and fixed armatures have been adopted in many of the recent alternators. For continuous-current dynamos the same remarks apply, only here sparkless commutation has to be provided for. Carbon brush blocks cannot be used, as at these speeds the brushes are apt to vibrate, and so diminish the intimacy of contact and cause heating and undue wear. The result is that it has been found best to form the brushes of wire, gauze, or foil, preferably of brass, and these must be sufficiently flexible so as to main-

tain a good contact with the commutator over the whole section of the brush. It follows, therefore, that the properties of the carbon brush blocks in giving sparkless commutation without alteration of the lead of the brushes, cannot in turbine-driven dynamos be utilized, and other means must be adopted to secure sparkless commutation at varying loads. One way is to shift the brushes automatically according to the change of load and this can be effected by connecting the brush gear to a steam cylinder controlled by a spring and supplied with steam from the point where the steam enters the turbine. At this point the pressure of the steam is proportional to the load of the dynamo, and therefore the piston in the steam cylinder being controlled by a spring takes up a position proportional to the load and thus shifts the brushes to the point of sparkless commutation. Another method is to provide commutating poles as proposed by Prof. Ryan and others, but the best method is to provide compensating winding as proposed by Prof. Forbes, Deri, etc. By these means, with the improvements recently adopted, absolute sparkless commutation can be secured with fixed brushes, up to, in plants for traction purposes, 100 per cent. overload.

Electrical Association Formed in North Dakota.

The organization of the Electrical Association of North Dakota was perfected in Grand Forks recently, with J. S. Leary of Valley City, president; J. S. Fuller of Larimore, secretary, and Thomas Roycraft of Grand Forks, treasurer. The next meeting will be held in Fargo in October.

New York Electrical Society.

The 243d meeting of the Society will be held at the Havemeyer Building, Columbia University, Wednesday evening, May 25. There will be a business meeting at 7:45, and at 8 o'clock Dr. M. I. Pupin will lecture on "Selective Signaling by Electrical Resonance." Dr. Pupin will explain the principles and the essential elements of this system of transmission. These elements are: The multi-frequency alternator, the transmitter, the distributors, the resonators and the rectifiers. At the special request of the U. S. Patent Office Commissioner, Dr. Pupin has prepared an exhibit for the pavilion of the U. S. Patent Office, at the St. Louis Exposition, illustrating by a complete model the transmission of telegraphic messages by alternating currents of various frequencies, the receiving and the transmitting apparatus being electrically tuned to the frequencies which they are intended to receive and transmit. This exhibit will be shown at the lecture. The lecturer will discuss at some length the application of electrical resonance on which the development of wireless telegraphy may so largely depend.

Removal.

The Bullock Electric Manufacturing Company has removed its New York offices to the Empire Building, No. 71 Broadway.

PERSONAL MENTION.

Mr. Harry J. Clark, chief engineer of the Syracuse (N. Y.) Rapid Transit Company, has been appointed assistant to President and General Manager C. D. Beebe, of the Rochester, Syracuse & Eastern Road and the Auburn & Syracuse Electric Road. He will have an active part in the construction of the new road connecting Rochester and Syracuse, which will be built this summer.

Mr. E. H. McHenry has been elected as fourth vice-president of the New York, New Haven & Hartford Railroad Company. Mr. Mellen, president of the road, says that Mr. McHenry is particularly well versed in the adaptation of electricity to standard gauge railroad operation and that his services are particularly desired in this direction.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED MAY 17, 1904.

Electric Railways and Appliances.

759,876. Trolley Wheel and Harp. Frank W. Garrett and Joseph D. Forrer, Johnstown, Pa., assignors, by mesne assignments, to the Westinghouse Electric & Manufacturing Company. Filed Dec. 26, 1901.

760,079. Trolley. Frank A. Overdier, Columbus, O. Filed June 30, 1903.

760,145. Guard for Trolley-Wheels. Charles O. Phillips, Kalamazoo, Mich., assignor of one-half to Hiram C. Streeter, same place. Filed March 2, 1904.

760,159. Electric Block-Signal System. Tony Silvene, Victoria, Canada. Filed May 29, 1902.

760,163. Trolley-Catcher. Irwin W. Smith, Dayton, O. Filed Jan. 25, 1904.

760,184. Trolley Pole-Head. Robert I. E. Dunn, Dallas, Tex. Filed Aug. 29, 1903.

760,223. Electric Railway. Thomas D. Lovell, Beverly, Mass., assignor of one-half to Robert M. Bailey, Deadham, Mass. Filed Jan. 22, 1904.

760,231. Trolley-Base. Peter D. Milloy, Buffalo, N. Y. Filed Nov. 16, 1903.

760,325. Electric Railway. William R. Fearn, Camden, N. J. Filed Dec. 16, 1903.

760,330. Trolley-Pole. James Furgason, Montour Falls, N. Y. Filed May 28, 1903.

Electric Lights and Appliances.

759,880. Electric-Arc Lamp. Otto Gross, near Manchester, Eng. Filed Dec. 11, 1903.

759,904. Regulating Apparatus for Theatrical Electric Lighting. Ernest F. Moy and Percy H. Bastie, St. Pancras, London, Eng. Filed Dec. 11, 1903.

759,925-926. Bracket for Electric Lights. Theodore Smith, Chicago, Ill. Original application filed July 27, 1903. Divided and last application filed Dec. 22, 1903.

759,962-963. Plural Lamp-Socket. Reuben B. Benjamin, Chicago, Ill., assignor to the Benjamin Electric Manufacturing Company, same place. Filed Dec. 9, 1901, and July 18, 1902.

760,376. Electric-Lamp Cluster. Reuben B. Benjamin, Chicago, Ill., assignor to the Benjamin Electric Manufacturing Company, same place. Original application filed Dec. 9, 1901. Divided and this application filed Nov. 12, 1902.

Electrical Machinery and Apparatus

759,873. Power-Transmission Device. William Evans and Paul W. Knauf, Philadelphia, Pa.; said Evans assignor of his right and said Knauf assignor of one-half of his right to said William Evans, John H. Evans and Robert Evans, Philadelphia, Pa., trading as John Evans' Sons. Filed Oct. 17, 1903.

759,915. Electric Switch. Max von Recklinghausen, New York City, assignor, by mesne assignments, to the Cooper Hewitt Electric Company. Filed April 22, 1902.

759,941. Plug-Receptacle for Electric Circuits. John H. Trumbull, Plainville, Conn., assignor to the Trumbull Electric Manufacturing Company, same place. Filed Oct. 9, 1903.

759,967. Alternating-Current Motor. Alexander J. Churchward, Brooklyn, N. Y. Filed March 29, 1897.

759,981. Electric Cable. Johannes Frisch, Mulheim-on-the-Rhine, Germany, assignor to Felten & Guilleaume Carlswerk Actien-Gesellschaft, same place. Filed May 5, 1902.

760,035-036-037. Steam-Turbine. Johann Stumpf, Charlottenburg, Germany, assignor to the General Electric Company. Filed Sept. 8, 1903.

760,077. Electrical Switchboard. Ernest W. Muller, Brooklyn, N. Y., assignor to Hubert Krantz, same place. Filed Nov. 20, 1902.

760,081. Automatic Switch-Indicator. Dewey S. Rice, Weatherly, Pa. Filed Dec. 24, 1903.

760,086. Dynamo-Electric Machine or Motor. Imle E. Storey, Amsterdam, N. Y. Filed Sept. 15, 1903.

760,091. Automatic Regulator for Electric Circuits Montgomery Waddell, New York City. Filed June 18, 1903.

760,160. Power-Transmitting Device. Clement Smith and Terry Stafford, Topeka, Kan. Filed Dec. 26, 1903.

760,209. Circuit-Controller. Paul H. Jaehnig, Newark, N. J., assignor to the Electric Motor & Equipment Company. Filed March 1, 1904.

760,289. Electrical Apparatus for Working Reciprocating Tools. Alfred D. Williamson and Cecil L. Sumpter, Sheffield, Eng., assignors to Vickers Sons & Maxim, Limited, same place. Filed Jan. 31, 1903.

760,387. Electric Switch. Egbert R. Dull, Chicago, Ill. Filed Aug. 5, 1901.

760,400. Automatic Oil-Switch. Max von Recklinghausen, New York City, assignor to the Cooper Hewitt Electric Company. Original application filed April 22, 1902. Divided and this application filed Jan. 6, 1904.

760,408. Dynamo-Electric Machine Leonard Wilson, Pittsfield, Mass., assignor to the Stanley Electric Manufacturing Company. Filed June 1, 1903.

Telephones and Telephone Apparatus

760,143. Apparatus for Amplifying or Reinforcing Telephone-Currents. Joseph J. O'Connell, Chicago, Ill., assignor to the American Telephone & Telegraph Company. Filed Aug. 22, 1903.

Miscellaneous.

759,910. Electric Separator. Alonzo H. Perry, St. Louis County, Mo. Filed Feb. 28, 1903.

759,987. Facsimile-Telegraph Apparatus. Ernst K. Gruhn, Dresden, Germany, assignor to the Telautograph, Gesellschaft mit Beschraenkter Haftung, same place. Filed Nov. 20, 1902.

760,012. Electric Self-Registering Target. Theodore F. Oetjen, Augusta, Ga. Filed April 14, 1903.

760,023. Apparatus for the Electrolytic Refining of Metals. Alfred Schwarz, New York City, assignor to the General Metals Refining Company, same place. Filed Nov. 22, 1902. Renewed Nov. 20, 1903.

760,029. Telegraph-Sounder. John F. Skirrow, East Orange, N. J. Filed Jan. 8, 1904.

760,057. Process of Electrically Smelting Materials. Alfred H. Cowles Cleveland, O. Filed Oct. 20, 1903.

760,075. Electrical Resistance. George I. Leonard, Pasadena, Cal. Filed Oct. 27, 1902.

760,076. Electric Heater. George I. Leonard, Pasadena, Cal. Filed Jan. 22, 1903.

760,096. Protecting Device for Vapor Electric Apparatus. James R. Baker, Arlington, N. J., assignor to the Cooper Hewitt Electric Company. Filed Nov. 6, 1903.

760,119. Means for Protecting Vapor Electric Apparatus. Peter C. Hewitt, New York City, assignor to the Cooper Hewitt Electric Company. Filed Dec. 22, 1903.

760,234. Electric Cab-Signal. Edward McClintock, Merriam Park, Minn., assignor of two-thirds to F. E. Butler and Edward Mierke, St. Paul, Minn. Filed Sept. 5, 1903.

760,280. Electric Water-Heater. Richard Toennes, Boonville, Mo. Filed Jan. 27, 1904.

760,281. Electric Alarm. Herbert Trull, Fernie, Canada. Filed Sept. 17, 1903.

760,315. Combined Electric Heater and Battery. Jesse R. Davis, Parkersburg, W. Va., assignor of one-third to Charles A. Wade, same place. Filed Dec. 8, 1903.

760,399. Selective Signal System. Fred C. Penfield and Olin Templin, Lawence, Kan. Filed March 17, 1902.

THE TELEPHONE WORLD.

Covington, Tenn., Without Telephone Service.

Because the city authorities imposed a tax of $1.50 per pole on the Cumberland Telephone Company which holds no franchise in Covington, the company has stopped its service and that city is no longer able to talk over the wires. The company feared that if it paid the tax other towns would make it do the same thing. The Memphis Telephone Company is arranging to install an exchange.

The New England Telephone & Telegraph Company will, within a few weeks, proceed to install a farmers' telephone system in Oxford, Mass., connecting the farms by wire with the outside world. It is probable that a farmers' telephone exchange will be established to include subscribers in Oxford, Sutton, North Oxford, Howarths, Buffums and the eastern section of Charlton, with headquarters in Oxford.

The Kinloch Long Distance Telephone Company of Missouri, according to St. Louis dispatches, has authorized an issue of $5,000,000 twenty-five year 5 per cent. gold bonds, of which $1,000,000 are to be placed at once. The mortgage covers all the lines of the company in Missouri, Kansas, Illinois and Indiana,

The People's Rural Telephone Company has met its first drawback in Clayton, Pa. The borough council has held up an ordinance granting privileges because of a disagreement on the height of poles.

The Round Top, Purling & Cairo Telephone Company of Cairo, N. Y., is a new concern, with the following directors: W. L. Richards, J. B. Edgerly and N. H. Griffin, all of Cairo.

The work of pole setting by the Hamilton, O., Home Telephone Company is completed through Venice, and the workmen are now nearing Shandon.

The Chesapeake & Potomac Telephone Company is contemplating the installation of a telephone system at Benwyn.

The German Independent Telephone Company of Gage County, Neb., has increased its capital stock to $5,000.

The Citizens' Telephone Company will install automatic 'phones in its Traverse City and Battle Creek, Mich., exchanges soon.

The Farmers' Interstate Telephone Company is installing about 50 'phones in the neighborhood of Lane, Ill.

A movement is on foot to establish a telephone company at Philadelphia, Miss., representing an investment of $10,000.

The Summerfield, Telephone Company of Noble County, O., capitalized at $5,000, has been formed.

The Farmers' Independent Telephone Company has been granted a franchise to enter the village of Upper Alton, Mo.

The Stryker, O., Telephone Company has increased its capital stock from $10,000 to $15,000.

Cost of Operating Automatic Telephones.

The Automatic Telephone Company of Chicago, whose stock is extensively held in Wilkes-Barre, Pa., and which operates under the Strowger patents, has issued a statement showing the comparative cost of operating with a manual telephone apparatus as compared with that of operating with an automatic system. The statement is made up from actual results obtained in the city of Grand Rapids, Mich., which used a manual board for six years, and in January, 1904, installed automatic apparatus manufactured by the Automatic Electric Company.

With 5,125 telephones in service in November, 1903, on the basis of one month's cost of operation with the manual board, the total cost per year was $51,024--147 people being employed. For the month of March, 1904, with 5,507 telephones in service and the automatic system in use, a total of 35 people were engaged, and the cost for the month was at the rate per annum of $26,292, or a saving of $24,732 in favor of the automatic system, the services of 112 persons being dispensed with. In both cases the cost of repairs and renewals was eliminated from the statement.

Citizens' Company of Columbus, O., Increasing Lines.

Work of extending the lines of the Citizens' Telephone Company was lately commenced on the viaduct. It will be pushed as rapidly as possible on both the north and east sides, and when completed, probably in January, 1905, over 4,000 new telephone connections with the central station will have been provided.

Most of the cables will be in conduits. While the underground and overhead work is being pushed the work on the company's new building, adjoining its present structure at Third and Long streets, will be rushed equally as fast and a new automatic switchboard installed, so that both will be finished about the same time.

The facilities of the company will almost be doubled when the plans under consideration are finally carried out. To make the improvements mentioned will necessitate an expenditure of nearly half a million dollars.

Many of the heavy cables that are now on the poles in the districts to be covered by the new conduits are to be taken down and placed in the conduits.

The Seneca County, N. Y., Home Telephone Company has connected its line with Geneva and now announces a long distance service to all points west, while in Waterloo and Seneca Falls it has extended its line until there are 108 'phones in Seneca Falls and 123 in Waterloo. It is extending its lines throughout the country.

Thomas Parmalee and Bert Pollock, president and superintendent of the Plattsmouth, Neb., telephone system, are working for the connection of the Plattsmouth and Lincoln systems.

The Bucyrus, O., Telephone Company has completed a new telephone circuit through Ridgeton, which will be known as the Ridgeton line.

Weather Reports by Telephone for Farmers.

The residents of 13 counties in Northern Ohio are being supplied daily, including Sundays and holidays, with weather reports from the United States bureau in Cleveland.

The reports are sent out at about 10 A.M., from the weather bureau office in that city, to the United States Telephone Company and from there they are telephoned to each town within the 13 counties. This is of especial benefit to the farmers and fruit growers.

The telephonic system of distributing the weather reports was started first in Iowa. It has been a success there. Forty thousand farmers receive the reports daily, besides the special frost and storm warnings. The reports thus reach the people who are interested several hours earlier than can be done by the use of mails.

The Pleasant Prairie, Wis., Telephone Company is reported to have notified the Wisconsin Telephone Company, with which it is now connected under a sub-lessee's contract, that it has elected to rescind the contract. If this is true it means that the Pleasant Prairie Company has decided to accept the offer of the Citizens' Telephone Company to purchase the small company at the price of $1,600.

The South Bethlehem Telephone Company was lately incorporated in Albany, N. Y., with a capital of $2,000 to operate a telephone system between South Bethlehem, Selkirk, Cedar Hill and Coeymans. The directors are E. C. Palmer, Charles D. Niver and J. R. Davidson, of South Bethlehem, and Newton B, Vanderzee, John W. Mosher, John B. Mosher and John F. Vrooman of Selkirk.

News from West Farmington, N. Y., states that the Pleasant Valley Telephone Company held its annual meeting a short time ago. The accounts were audited and it was found that after paying all bills there was quite a surplus in the treasury. The officers were re-elected for another year with the exception of treasurer, which office was filled by Frank Weeks. The line is to be extended and better service rendered than heretofore.

Rural telephones will soon connect all parts of Sonoma County, Cal. A franchise, was applied for by residents of the Two Rock and Penn Grove sections at a recent session of the board of supervisors. Six different systems have been installed during the past two months.

The farmers in the neighborhood of Okolona, O., a little village about six miles west of Napoleon, have formed a Farmers' Mutual Telephone Company, and ordered a 100 drop switchboard. J. W. Durham is president.

The net output of the American Telephone & Telegraph Company for the month of April decreased 366 instruments as compared with the same month last year.

There is soon to be established in Akron, N. Y., a Citizens' Telephone Company. The capital will be $10,000. Most of the stock has been taken by residents of that village.

GENERAL ELECTRICAL NEWS.

LIGHTING.

Addison, Mich.—This town wants electric lights.

Addison, N. Y.—The building with its contents containing the electric light and water company's machinery was lately destroyed by fire, entailing a l)ss of $70,000.

Brewton, Ala.—The city electric light and waterworks plant was damaged considerably by a recent fire.

Carrollton, Ga.—An election is to be held June 4 to vote on the matter of issuing bonds to the amount of $45,000, for waterworks, sewerage and electric light purposes.

Cape May Point, N. J.—The streets of this place will be lighted with electricity during the summer.

Carthage, Ill.—The Carthage Electric Light & Power Company has increased its capital stock from $20,000 to $50,000, and changed its name to the Carthage Electric Light & Heating Company. The plant will be enlarged.

Conroe, Tex.—W. H. Clark, merchant, is arranging to put in a small electric light plant to supply lights for the business section of this city.

Cookeville, Tenn.—It is now thought to be almost an assured fact that the Gainsboro Telephone Company will in the near future erect an electric light plant in this city.

Deland, Ill.—The council is figuring on putting in an electric light plant at a cost of $6,100.

Duquoin, Ill.—An,electric light plant is under consideration. Job Cook, city clerk, Box 88, may be addressed.

Freeburg, Ill.—The amount of $5,000 has been voted for an electric light plant. John Sintzeley, clerk.

Janesville, Minn.—This town will soon offer bonds for sale for an electric light plant.

Joplin, Mo.—On June 6 the citizens will vote on the issuance of $30,000 bonds to improve the city lighting plant.

Kilbourn, Wis.—The village board is considering the question of lighting the village by electricity.

Middletown, Ill.—There is a rumor that electric lights are to be established here.

Montague, Mich.—This town is reported to be considering plans for an electric light plant.

Norwich, N. Y.—S. N. Blake, of the Norwich Gas & Electric Company, promises improvements in street lighting.

Oyster Bay, N. Y.—The Oyster Bay Electric Light & Power Company is preparing to equip its plant with more power to meet the requirements of its business. It has also adopted a new shunt lamp, which will remove the danger of the light being extinguished from any ordinary cause.

San Francisco, Cal.—A meeting of the stockholders of the Mutual Electric Light Company has been called for June 21 to vote on an issue of $400,000 5 per cent. gold bonds, of which $250,000 will be for immediate improvements.

Schoolcraft, Mich.—The power house of the electric lighting plant here was lately destroyed by fire.

West Point, Ia.—The electric light proposition is being agitated here.

Williamstown, N. J.—The township committee has advertised for bids for lighting this town with electricity.

STREET RAILWAYS.

Bessemer, Ala.—The proposed line of the Brookwood Electric Company will be constructed and equipped for $260,000.

Columbus, O.—Superintendent Ralph Peters, of the Pennsylvania lines, has confirmed a report that the Cincinnati & Muskingum Road is planning to equip the line from Trinway to Lancaster with electric power, so as to compete with interurban lines that are contemplated.

Decorah, Ia.—It is stated on the authority of men who are financially interested in the project that the proposed electric line between here and Chatfield, via Preston, is now a certainty, and that the work has partly been laid out for a considerable distance from this city, and the full right of way to Chatfield has been secured.

Emporia, Kan.—Hugh Holmes, of Kansas City, who is building an electric railroad from Kansas City into Central Kansas, is interesting local business men in building a line from Ottawa to this city.

Evansville, Ind.—William L. Sonntag has organized a company here to build an electric line from this city to Rockport.

Glasgow, Mo.—Col. W. H. Chase is the promoter of the Missouri Central Electric Railway here.

Kalamazoo, Mich.—The common council has granted a franchise for an interurban electric line, which it is proposed to build between here and Benton Harbor. This will, if built, be the only road through the peach and grape belt.

Lansing, Mich.—The West Michigan Interurban Railway Company, with a capital stock of $1,000,000, has filed articles of incorporation with the Secretary of State. The organization is effected to build a trolley road from Grand Rapids via Muskegon to Park, Oceana County. F. A. Nims, of Muskegon, and ex-Senator J. K. Flood, of Hart, are among the incorporators.

New Decatur, Ala.--Parties from the Decaturs, Florence, and elsewhere, are contemplating the building of an electric street railroad from this city to Moulton, in Lawrence County, a distance of about 20 miles.

New York City.—The electrical equipment of the New York City terminals and the suburban lines of the New York Central is expected to be pushed actively, now that funds have been provided by the recent negotiations of the company's $30,000,000 debenture bond issue. In discussing the improvement plans lately W. J. Wilgus, fifth vice-president and chief engineer of the New York Central, said that electricity would be used not only in the tunnel, but also to White Plains, on the Harlem, and to Ossining or Croton Landing on the New York Central.

Olean, N. Y.—There is talk of an electric road running from Addison to this place via Woodhull, Rexville, Whitesville and Wellsville, thence to Bolivar, connecting with the line of that village to Olean.

Trinidad, Col.—It is understood that the Trinidad Electric Railway Company contemplates very shortly extending its line from this city to Aguilar 26 miles north. P. M. Johnston is one of the promoters.

Wallingford, Conn.—The new electric road of the Wallingford Tramway Company will soon be built.

West Point, Va.—The New Point Comfort Company has been canvassing some of the lower Tidewater counties soliciting subscriptions for an electric line. If the counties to be benefited by the company take $25,000 of the company's stock it is asserted that an electric railway from New Point Comfort to this place will be completed this year. Mathews and Gloucester County are expected to subscribe this amount.

POWER PLANTS.

Baker City, Ore.—The Oregon Power & Development Company has been incorporated with a capital of $200,000. An electric plant will be constructed in the Greenhorn mining district on Granite Creek. Water power will be obtained from Granite, Boulder and Sunrise Creeks.

Duffryn Mawr, Pa.—The Ridley Creek Electrical Supply Company has purchased the John G. Smedley farm, in Willistown Township, Chester County. There is a fine water power on this property of sufficient energy to produce abundant electricity. The company proposes to furnish light and power to this place, Paoli, Malvern and other adjacent points along the Pennsylvania Railroad.

Eureka, Cal.—The Eureka Lighting Company will erect a power plant about four miles below Hyampom. Surveys will be started soon.

Granville, N. Y.—The Granville Gas, Electric Light & Fuel Company, composed mostly of Sandy Hill capitalists, is about to begin the erection of a dam at Lake St. Catherine, near here. About 2,000 hp. will be developed. Surveyors are now on the preliminary work, and as soon as the work of constructing the dam is under headway the building of a line to Whitehall and furnishing electricity for light and power will be begun.

La Grande, Ore.—J. K. Roming, manager of the Sanger mines here, states that a large power plant is to be installed at the mines soon.

Lowell, Kan.—W. O. G. Sergeant is preparing to begin construction on a mammoth power plant at this place, 16 miles west of Joplin.

Quincy, Cal.—The Quincy Water & Power Company has been incorporated by J. D. Goodwin and others with a capital stock of $50,000. The waterworks will be improved and an electric power plant installed.

San Francisco, Cal.—The park commissioners are considering a plan to install an electric power plant in Golden Gate Park. The new equipment would cost $7,200.

BIDS WANTED.

Vancouver, Wash.—Sealed proposals in triplicate will be received until June 9 by F. G. Hodgson, quartermaster, for constructing an electric lighting system at the Vancouver barracks.

Woodville, Miss.—Sealed bids will be received by the mayor and board of aldermen of this place until June 7 for the erection of a system of waterworks and electric light plant. D. C. Bramlette, treasurer; C. N. Jenks, engineer, Fayette, Miss.

NOTES FOR INVESTORS.

Latest quotations for copper are: Electrolytic, 13@13⅛c.; Lake 13⅛@13¼c.; casting, 12⅞@13c.

The Illinois Traction Company, capital $4,000,000, has been incorporated at Augusta, Me.

It is reported that the Chicago Telephone Company will issue $1,000,000 new stock within a few weeks.

The Philadelphia Electric Company has declared the regular semi-annual dividend of 18¾ cents a share, payable June 15.

The Bell Telephone Company of Missouri has been given authority to increase its capital from $4,000,000 to $10,000,000.

A special meeting of the stockholders of the Tampa (Fla.) Electric Company has been called for May 30, to increase the capital stock by the amount of $100,000.

The New England Telephone & Telegraph Company will in all probability issue additional stock this summer for new construction.

Official notice has been received by the New York Stock Exchange from the General Electric Company of the increase of its capital stock from $45,000,000 to $48,325,000.

The United Traction Company of Albany, N. Y., has given to the Central Trust Company of New York a mortgage of $6,500,000 to cover an issue of 6,500 gold bonds of $1,000 each.

Phelps-Dodge people say that under general business conditions 13 cents is a fair price for copper and they are willing to fill orders at this price. They rather look for prices to hold around a 13-cent level.

It is estimated when the full plans of the Public Service Corporation are carried to completion this company will own or control practically all the street railway and gas companies of any importance in New Jersey.

The Massachusetts Electric Companies now has $20,557,400 of preferred and $14,293,100 of common stock outstanding, back of which are 165,000 shares of underlying stocks, or a ratio of 1¼ to 1 in preferred and ¾ to 1 in common stock.

The board of directors of the United Railways & Electric Company of Baltimore, at a meeting Thursday, will decide upon what action will be taken in regard to the payment of the June coupon on the income bonds.

By the payment recently of the final installment on its new stock, the Boston Edison Company has taken up about $500,000 of its notes leaving at present $1,000,000 still outstanding. These notes are of various maturities, the longest being for a year, and the latter bearing a 4 per cent. interest rate.

It is again rumored that payment of dividends on New York Interborough stock may begin this summer, the surplus earnings of the elevated lines after providing for the full 7 per cent. dividend on Manhattan stock being sufficient to warrant the lessee company in making a distribution to its own stockholders.

President C. S. Mellen has announced that formal merger will be made this week of the Meriden (Conn.) Electric Railway Company and the Consolidated Railway Company, both of which are controlled by the New York, New Haven & Hartford Railroad Company. Friday the merger of the Winchester Avenue Railroad Company and the Fair Haven & Westville Railroad Company, comprising the traction service of New Haven, and the Consolidated Railway Company, was officially made.

ELECTRICITY.

VOL. XXVI. NEW YORK, JUNE 1, 1904. NO. 22.

ELECTRICITY.

Published every Wednesday by the
ELECTRICITY NEWSPAPER COMPANY.

Publication Office, - - 136 Liberty St., New York.
Long Distance Telephone, 4021 Cortlandt

SUBSCRIPTION RATES:
United States, Canada and Mexico..$1.00
Foreign Countries........................ 3.00
Single Copies........................10 cents
Remit by Draft, Post Office Order, Registered Letter, or in Stamps.

Owing to the expense involved in keeping back numbers, papers over two years old will be charged for at the rate of 25 cents apiece.

ADVERTISING RATES.
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily understood. Rates will be sent on application.
Changes of advertisements should reach the office not later than Saturday morning preceding the day of publication.

Entered at the New York Post Office as second-class mail matter.

THE TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY.

EDITORIAL NOTES.

The Boston Convention.

The Twenty-seventh Convention of the National Electric Light Association, which was held last week in Boston was eminently successful and satisfactory. In spite of the fact that the "Hub" can hardly be termed a hub so far as the electric lighting industry is concerned, and though it might more aptly be likened to a point half way up the spoke, there was no lack of delegates, over four hundred being present from all parts of the country.

The papers dealt with subjects of vital interest to the industry, and what is more were very thoroughly discussed, which has not always been the case in the past.

The social features were as usual everything that could be desired, and though the weather was fine it was warm.

The proceedings as well as several of the papers presented will be found elsewhere in this issue.

* * *

Coast Government Control.

Advices from San Francisco state that for the first time on the Pacific coast communication has been had by wireless telegraphy between a ship at sea and points on shore. The United States hospital ship Solace sailed from the above port recently and until she was 70 miles out messages were sent between the Solace and the Weather Bureau's stations at Point Reyes, on the mainland, and on the Farallone Islands, which lie off that city. Conditions were very favorable, and communication was continued without a break for five hours.

The local Weather Bureau has been informed by Willis L. Moore, chief of the service, that all the California observation stations and those on Tatoosh Island and North Head, in Washington, will soon be equipped with the latest instruments.

In connection with wireless telegraphy stations along the coast it is interesting to note that steps are about to be taken to place them all under Government control. This decision has been reached by a committee of Cabinet members to whom the question was referred. If it is carried out it will seriously interfere with Marconi and his Cape Cod station, from which point he proposed to establish communication with England. The Marconi station on Nantucket lightship has already been ordered discontinued, and the Navy Department has established a modification of the Slaby-Arco system, which is in use on German ships. The Navy Department has established with considerable secrecy seven stations along the north Atlantic coast. The Government proposes to handle free messages to or from persons on ships at sea, turning such messages over to the telegraph companies to be forwarded to destination.

In the opinion of many it will be impossible to make wireless telegraphy valuable for commercial purposes, or in time of war, unless its control is vested in the general Government.

Alternating Current Measuring Instruments.

Mr. W. Duddell, whose oscillograph is now so well known, described some new instruments, for the measurement of large and small alternating currents, before a recent meeting of the Physical Society in London. They were three thermal instruments of his own construction. One was essentially a sensitive Ayrton-Perry twisted strip ammeter, which is very quick in action for a thermal instrument, and has been used for observing and recording potential differences and currents which varied as

rapidly as one per second. It is compensated for change in the surrounding temperature by forming the sides of the frame which holds the twisted strip with the same wire that the strip itself is made from.

Mr. Duddell exhibited an instrument in which a current of 22 milliamperes gave a deflection of one-quarter the scale-distance, i.e., 250 ohms at one meter scale-distance. The mechanical periodic time is only about one-fifteenth second. Using this instrument in series with a high resistance Mr. Duddell has made observations on the variations in the voltages of alternators caused by cyclic irregularity of the engine. By working to a false zero it is easy to obtain 10 mm. change in deflection for one per cent. change in the potential difference.

The second instrument exhibited was a very sensitive thermal galvanometer called a "thermogalvanometer." It is a combination of a radio-micrometer of the "Boys" type with a very small resistance which is heated by the current to be measured, and which in turn heats the thermo-junction of the radio-micrometer by radiation and convection. The principle of its action may be described thus: A loop of wire has its two ends fixed to the two bars of a single thermo-junction, a mirror is fixed to the loop, and the whole is suspended in a magnetic field by means of a quartz fiber. The heat from the resistance raises the temperature of the thermo-junction and causes a current to flow round the loop which is deflected by the magnetic field. The sensibility of the instrument depends on the resistance of the heater. Using a heater having a resistance of 13,910 ohms, a deflection of 250 mm. at a scale distance of one meter is obtained with a current of 31 micro-amperes; a heater having 18 ohms resistance required 800 micro-amperes to give the same deflection. Mr. Duddell, in order to illustrate the high sensibility of this instrument showed the large deflections produced by the currents through a telephone receiver even when the source of sound was many feet distant from the microphone. He also showed that if the thermogalvanometer was placed in series with the vertical receiving wire in spark telegraphy over a short distance, large deflections were produced.

The third instrument was a switchboard instrument which works on the same principle as the last, only the moving part is pivoted in the usual way. One of the instruments, which was exhibited to the Physical Society audience, was arranged to give the whole scale deflection for only 0.15 volt; this can be used in connection with shunts to measure large currents; for instance, to measure 1,000 amperes the power lost in the shunt would only be 150 watts. Transformers can also be used as the power to produce the whole scale deflection is only 0.3 watt. The author also placed on view a similar instrument with a high resistance heater; it gave the whole scale-deflection for 0.1 ampere, and can be used as a voltmeter by putting resistance in series with it.

UNDER THE SEARCHLIGHT.

Notes and Comments on Various Topics.

Among the examinations of the United States Civil Service Commission, to be held at Albany, N. Y., June 22-23, are electrical and civil engineering, at salaries from $1,200 to $1,400 per annum in the Philippine service.

A dispatch from Berlin announces the death of Wilhelm von Siemens, of the Siemens & Halske Company. He was a member of the famous Siemens family, whose inventions have been foremost in the modern industry of electrical engineering. He was frequently consulted by the Emperor William, especially in connection with the electric line at Zossen.

It is reported from Boston that Boston and Worcester street railway interests are considering plans for the building of a double track, high speed electric line from Boston to Providence, to enter into active competition with the New York, New Haven & Hartford Railroad Company. The cost is estimated at $2,500,000.

Dr. M. I. Pupin, of Columbia University, lectured before the New York Electrical Society, in Havemeyer Hall, on May 25, on a method which he has perfected for sending telegraph messages. Dr. Pupin said that his invention would admit the sending of six messages simultaneously over a single line, to a greater distance, and more rapidly than is possible at present. He also said that a lighter wire than is now common could be used. Dr. Pupin exhibited a model of his invention and explained its workings in detail. This model is to be sent to the pavilion of the United States Patent Office at the St. Louis Exposition.

A fireproof insulation for electric wires, which, it is believed, will remove one of the most frequent causes of fires in buildings in which electricity is used, was described recently by Dr. William H. Easton, of York, Pa., at a meeting of the Franklin Institute. The new insulation, which has recently been perfected after years of experiment, consists of a covering of asbestos chemically united by the action of heat, with a cement, producing a hard, flexible waterproof and fireproof sheathing over the wire.

Members of the New York Rapid Transit Commission are looking with decided favor on the proposition made by the Schmidt & Gallatin Syndicate, in connection with the Belmont interests of the the Interborough Rapid Transit Company, to install a system of moving platform subways in the crosstown streets so as to provide an interchangeable transfer system between these subways and the Interborough subways and elevated lines.

A telegraph instrument has been invented that is attracting the attention of railroad telegraphers. It is called a mecograph and is a small simple contrivance about the size of an ordinary relay. It is composed of a baseboard, a standard from which is suspended a pendulum, a key, two binding posts for a split cord, on the end of which is a wedge that fits in the Morse key, and one or two other essentials. From the bottom of the pendulum, which forms one pole of the wire, extends a flat spring carrying a platinum point which, when set in motion, vibrates between two points or bumpers, one of which forms the opposite pole. The advantage the inventor claims for the instrument is that it reduces the work of the operator. In making a six dot figure but one movement is necessary.

United States Commercial Agent Harris at Eibenstock has made a report to the State Department of the industrial schools in Saxony, which have been founded for the sole purpose of training young men to become competent and skillful locksmiths and blacksmiths. These schools are located in the following cities: Burgstadt, Grossenhain, Frankenberg, Meissen, Glauchau, Rosswein and Zittau. The report contains an interesting account of the course of studies in these schools, and shows an extra cost for advanced training in electrical science. Special attention is called to the number of hours devoted to practical instruction in the workshop. There the students are drilled in the art of constructing and laying telephones, telegraphs and lightning rods, as well as of drawing and constructing machinery of every description for the application of electricity and steam.

PROCEEDINGS OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION CONVENTION AT BOSTON

President Charles L. Edgar called the 27th Convention of the National Electric Light Association to order at 10:45 A. M. on Tuesday, May 24, at the Hotel Vendome, Boston, and said: "I take great pleasure in calling the 27th Annual Convention of the National Electric Light Association to order. The first business will be the reading of acceptances of invitations to attend this meeting and letters of regret at not being able to do so, from various gentlemen, both past presidents, honorary members and distinguished gentlemen whom we have invited to attend.

Several letters were read by Secretary Davis, among them one signed by Thomas A. Edison, saying that he would like to be in attendance but at present was "having so much trouble" with his stomach that it seemed "uncertain." Then President Edgar read his address, saying:

THE PRESIDENT'S ADDRESS.

"It is now 17 years since this association met in Boston, and I cannot resist the opportunity to make a few comparisons between the year 1887 when this association met at the Parker House, and the present year. It was my pleasure to attend that convention as a guest of our old friend, Captain Brophy, and I have a somewhat distinct recollection of the meetings and of the entertainments. I know it was with considerable anticipation that I looked forward to the visit to the works of the Thomson-Houston Company in Lynn, then rated as one of the largest works of its kind in this country, and yet the number of men employed in the entire works at that time was not as many as it now employs in almost each one of the dozen departments.

"At that time, too, the Boston Edison Company, who, with friends and associates in Boston, is one of those to welcome you here to-day, was the proud possessor of one small station, with total load connected to its overhead system equal to the fortnightly growth of the present year. In those days, too, the horse cars made their weary way along the Tremont street mall of Boston Common. To-day not only horses, but cars and tracks have disappeared, and under this same mall is located one of the finest electrically operated subways in the world.

"We are astounded when we turn our gaze upon our own business as represented by the members of this association distributed throughout the United States and Canada. The number of electric light stations has increased during these 17 years more than ninefold. Naturally the membership of this association has not grown in proportion, but the fact that there are now on our rolls 588 members as compared with only 158 at that time, is a matter for sincere congratulation."

Mr. Edgar called attention to the need of a change in the association by-laws. When the body was organized, 19 years ago, there was a large number of small companies. Consolidations have wiped out the small companies or absorbed them, and their membership in the National Association has disappeared. In the Boston district the membership has thus been cut down from seven to one. The President suggested a new class of memberships to make up for those thrown out by the absorption of their companies,

ERNEST H. DAVIS,
President-elect of the National Electric Light Association.

this class to consist of "junior active members," to be elected under some sort of supervision from the active members, with whom they are connected in business, and paying dues, an amount in keeping with their privileges.

The President noted the lack of a comprehensive and correct directory of the electric lighting industry, and announced that this lack was about to be remedied by the action of one of the association members. An index of the association records has also been undertaken.

One novel paragraph in President Edgar's address was the one calling attention to the new use of the service of electric companies last winter in thawing water pipes, and he suggested the appointment of a reporter to look into the subject, to collect and distribute to members the experiences of the various companies in this respect.

President Edgar recommended a strong, permanent committee to deal with the subject of municipal ownership of electric lighting plants.

Mr. Henry L. Doherty—Mr. President, it has been customary to refer the address of the President to a committee to report upon the recommendations contained therein. The address you have just heard probably contains as many, if not more, valuable suggestions for the future conduct of the association than any of the addresses we have heretofore heard. It is a comprehensive effort to put the affairs of the association in better shape, and I move, Mr. President, that the Secretary be instructed to appoint a committee of three to consider and report upon the recommendations in the President's address.

The Secretary put the motion, which was carried, and the Secretary appointed as such committee Henry L. Doherty; George W. Brine and H. T. Hartman.

President Edgar—I desire to announce that the sessions of the convention will be called to order strictly on time, and the chair hopes that the members will be punctual in their attendance, so that we may proceed with the business in a proper manner and have sufficient time to consider all the papers. The first paper on the programme is one on a subject which was new last year, but which was such a success that it is repeated this year, and I have no doubt that will be repeated indefinitely at our future meetings. I take pleasure in introducing Mr. T. Commerford Martin, of New York, who will present a report on "Progress."

Mr. Martin—Mr. President, I understand from the remarks which have been made, regarding the papers being in type and sent to the members of the association a week ago, that it will hardly be necessary to read the papers in full. Mine was one of the papers in type. The members have, therefore, had a full week in which to determine the value of its contents, and I hardly think it necessary for me to take up your time in presenting merely an abstract of the paper.

Mr. Martin called attention to the run of the contents of the report. (An installment of the report will be found on another page of this issue of ELECTRICITY.)

The President—We will now proceed to the next paper, "A Three-Wire, 500-Volt Lighting System," by Mr. Walter I. Barnes, Providence, R. I.—Mr. Barnes read the paper and it was discussed by

Messrs. Woodward, Whitfield, Junkersfeld, Ferguson, Dow, Williams, Doherty, Gossler and Hallberg. Capt. William Brophy brought out many important points in the discussion.

The President—We will close the discussion on this paper and take up the paper on "The Luminous or Flaming Arc," by Mr. Welles E. Holmes of Newton, Mass.

Mr. Holmes read the paper, which was discussed by several members.

The President—I have on this morning's programme the reports of four committees, all of whom are going to ask to be discharged, and I think possibly it would be well to adjourn this business until the beginning of the afternoon session. It won't take over five minutes to discharge the four committees, as they request.

On motion adjourned until 2:30 P.M.

AFTERNOON SESSION.

President Edgar called the meeting to order at 2:30 o'clock promptly.

The President—We will now take up the consideration of the reports of the four committees which were left over rom the morning session. We will first consider the committee Report on Uniform Accounting, of which Mr. Guy L. Tripp, of Boston, is chairman. Mr. Tripp wrote me a letter, saying that he regretted he could not be present at this meeting and said he had nothing further to report as chairman of the committee.

The President—The Committee on Legislative Policy is another of these committees. Mr. Samuel Insull, of Chicago, the chairman of this committee, is abroad. The committee has done no work for several years.

Mr. W. M. Anthony, Chicago—I move that the committee be discharged. Motion carried.

The President—The Committee on Standard Candle Power of Incandescent Lamps, Dr. Louis Bell, chairman, and the Committee on Photometric Values of Arc Lamps, Mr. Henry L. Doherty, chairman, are the two remaining committees to be considered, but as the chairmen of these committees are not in the meeting room, although present at the convention, we will pass those for the present. We will now take up the paper, "A One Hundred Mile Transmission Line," by Mr. Robert Howes, Spokane, Wash.

Mr. Howes read the paper and at its conclusion added: "Since I wrote this paper we have received the regulator and gotten it installed in time for me to know the results before I left Spokane. We succeeded in holding our voltage at Spokane practically steady. There was a variation not to exceed ¾ of a volt above or below the normal on a 116-volt basis. At the other end of the line this cut down the variation to a trifle over one-half of what we had before. Then the controller for the motor arrived, but without a time relay device. When that was installed we cut down the variation at the other end to one-half of what it was then, leaving us with a variation of ¼ at the other end of the line to what it was when we wrote this paper. We now have variations of 5 to 6 per cent. on either end of the line in extreme cases."

The President—The paper on "Grounding the Neutral of High Voltage Generators," by Mr. George N. Eastman, of Chicago, will now be considered.

Mr. Eastman presented the paper and a short discussion followed.

The President—The next paper is on the "Remote Control of Electrical Apparatus," by Mr. William H. Cole, of Newton, Mass.

Mr. Cole presented the paper.

The President—We will proceed to the next paper, "The Organization and Equipment of an Arc-Lamp Department," by Mr. Samuel G. Rhodes, New York.

Mr. Rhodes read the paper.

The President—I want to say one thing in regard to Mr. Rhodes' paper. Of all the papers asked for in advance by members to whom I sent a list of the papers, this paper was asked for by more delegates than any other paper before the convention. Mr. Rhodes' paper seems to be such a complete story of the whole subject, that I judge, from the absence of any gentlemen arising to discuss it, that there seems to be no member who wants to know more about it. It seems a shame to pass such a paper without a very thorough discussion.

The President—We will take up the next business, which is the report on "Lost and Unaccounted for Current," by Mr. C. W. Humphrey, Denver, Col.

Mr. Humphrey presented the report, and after a short discussion the meeting adjourned until 10 o'clock on Wednesday morning.

Wednesday, May 25.

MORNING SESSION.

President Edgar called the meeting to order at 10 o'clock promptly and announced the first paper on the programme to be that on "Economy in Minor Station Supplies," by Mr. Edgar B. Greene, of Altoona, Pa.

Mr. Greene read the paper.

The President—The next paper in order is that on "Notes on the Internal-Combustion Engine as Applied to Central Station Service," by Mr. E. E. Arnold, of Pittsburg. Pa.

Mr. Arnold presented the paper.

The President—We have three or four papers on kindred subjects this morning, and with your permission I am going to ask the gentlemen who are to take part in the discussion of these papers to wait until the papers have all been read and then we will have a general discussion of all of them at the same time. Pursuing that policy, we will have the paper on "Economy Test of a 5,500 Horse-power, Three-Cylinder, Compound Engine and Generator," by Messrs. J. D. Andrew and W. F. Wells, New York.

Mr. Andrew read the paper.

The President—Gentlemen, with your permission I am going to change the order of programme just a trifle and pass the paper on "Mechanical Stokers" for the next half hour, and take up the paper or report of the Committee on Investigation of Steam Turbines, Mr. W. C. L. Eglin, of Philadelphia being the chairman of the committee.

Mr. Eglin presented the report of the committee.

The President—I have asked both the General Electric Company and the Westinghouse Electric & Manufacturing Company to either prepare papers on this subject of steam turbines, or to discuss them. Mr. Rice is here prepared to discuss the subject, and Mr. Hodgkinson has prepared a paper on it.

Mr. Louis A. Ferguson—Mr. President and gentlemen, I know that Mr. Eglin and his associates have spent a great deal of time during the year in preparing this report, and I therefore move that a vote of thanks be given Mr. Eglin and his associates for this excellent report which they have presented.

Mr. Ferguson's motion was put and carried.

The President—We will now take up the paper on "Practical Notes on Steam Turbines," by Mr. Francis Hodgkinson, of Pittsburg, Pa.

Mr. Hodgkinson read the paper.

DOHERTY MEDAL AWARDED.

A pleasing feature was the award of the Doherty gold medal for the best paper on "Underground Electrical Construction. The winner was W. P. Hancock, at present general operating superintendent for the Boston Edison Company. Dr. Schuyler S. Wheeler, of Ampere, N. J., who, with Past President L. A. Ferguson, and H. G. Stott, of New York, composed the committee of judges, in announcing Mr. Hancock's success, said that a paper by John D. Blood had been very highly commended and was so well

put together as to be remarkable in that respect, but Mr. Hancock's paper showed such mastery of detail and covered the whole subject so completely that the members of the committee, though acting independently, had each concluded that Mr. Hancock deserved the prize. Past President Doherty said he had been constrained to offer the medal by the need of standard practice in underground construction and he hoped the competition had done something to stimulate such uniformity.

The President—We will now have the paper on "The Mechanical Stoker and the Human Operator," by Mr. Edwin Yawger, Pittsburg, Pa.

Mr. Yawger read the paper, which will be found in this issue of ELECTRICITY.

On motion the meeting adjourned until 10 o'clock on Thursday morning.

Thursday, May 26

MORNING SESSION.

President Edgar called the convention to order at 10:30.

The first paper was on "Electric Light and Power Plants in Connection with Ice Plants." The author, Mr. C. L. Wakefield of Dallas, Tex., was not present and the paper was read by Mr. Maunsell. In the discussion points were brought out to show the value of the installation of refrigerating plants operated by electricity.

The committee on nominations was appointed as follows: P. G. Gossler, D. P. Robinson, Irvin Butterworth, W. C. L. Eglin and F. E. Smith.

The report of the committee on the President's address was presented by Mr. H. L. Doherty, chairman. The convention approved the recommendations of the President.

The report of the Committee on Purchased Electric Power in Factories was read by Mr. W. H. Atkins, chairman, and was discussed by Louis A. Ferguson, Arthur Williams, P. G. Gossler, Charles B. Burleigh and J. F. Dumesmay.

The report of the committee on Purchase Electric Power in Factories called out a protracted and interesting discussion after which the convention adjourned until 2:30 P.M.

AFTERNOON SESSION.

The report of the committee on District Heating was the first business taken up in the afternoon session. This report was presented by Mr. E. F. McCabe of Lewiston, Pa. The report on Office Methods and Accounting was presented by Mr. Frank W. Frueauff, of Denver. A paper on "A Proposed System of Standard Instruments for Operating Companies," by Mr. H. P. Davis, of Pittsburg, was read. This was followed by the paper on "Single-Phase Power Motors for Electric Lighting Stations," by W. A. Layman, of St. Louis.

At the executive session held on Thursday evening, the reports of the Executive Committee, Secretary and Treasurer, and the Committee on Finance were presented.

The Treasurer's report showed the following transactions during the year:

Balance, 1903	$ 8,651.90
Receipts	11,214.00
Total	$19,865.90
Expenses	10,392.17
Balance, 1904	$9,473.73

Mr. William Brophy presented the report of the Committee on Standard Rules for Electrical Construction and Operation.

THE NEW OFFICERS.

The Nominating Committee presented the following nominations: President, E. H. Davis, Williamsport, Pa.; First Vice-President, W. H. Blood, Jr., Seattle, Second Vice-President, Arthur Williams, New York; Secretary and Treasurer, Dudley Farrand, Newark; Executive Committee, Samuel Scovil, Cleveland; H. A. De Camp, Philadelphia; W. F. White, St. Louis.

On motion, a vote of thanks was passed to the New England Electrical interests for the very elaborate entertainment and many courtesies received by the delegates.

A vote of thanks was passed to President Edgar for the efficient manner in which he has presided over the convention, and for the very great amount of work he had performed in the interests of the asssociation during the term of his Presidency.

President E. H. Davis was escorted to the chair by Messrs. Doherty and Ferguson and upon his installation assured the convention that all his efforts would be entirely devoted to the success and best interests of the association.

Ex-President Edgar acknowledged the courtesy of the members to him during his administration, and the meeting adjourned.

Obituary.

It will be learned with regret that Thomas Rowland Western, cashier of the Manufacturers' Advertising Bureau, New York, of which Benjamin R. Western, his father, is the proprietor, died suddenly on Sunday, May 22, after an illness of only a few days. Mr. Western was of a genial and accommodating disposition, and will be missed by many admiring friends.

REPORT OF THE COMMITTEE ON PROGRESS.*

BY T. COMMERFORD MARTIN.

The central station industry of the United States has enjoyed since this association last met, in Chicago, another year of marked advance and prosperity. Although the period has been one of uncertainty and disturbance in the financial markets, the disasters of speculation thus thwarting the legitimate hopes and ambitions of industrial enterprise and checking new investment, electric lighting has experienced no setback. The rate of gain over previous periods has apparently been maintained, if indeed it has not been accelerated.

Statistical data are the first that should receive consideration, and fortunately we now have a firm basis upon which we can found our study and analysis of the figures of electric light and power. When I had the honor to present my report last year as Committee on Progress, the United States Census statistics were not available as to the growth and status of the art. They have since been published, and are perhaps now familiar. As special expert for the Government in connection with this work, and having an opportunity, therefore, to test the work done, I can speak with praise in regard to the conscientious, intelligent and painstaking manner in which Messrs. S. N. D. North (now director of the Census Office) and W. M. Steuart (now chief statistician for the Department of Manufactures in the Census Office) sought to verify and confirm every statement given out.

FIGURES OF THE INDUSTRY.
